Results: Four key themes emerged from the analysis. First, there was a lack of awareness of TC as a service. Many participants were unfamiliar with the term "teleconsultation," perceiving it as technical jargon, and found doctors' explanations insufficient. Second, limitations in TC service processes led to confusion and dissatisfaction. Patients were uncertain about medication collection after TC session and viewed TC as redundant when in-person visits were still required to obtain medicines. Third, patients felt that TC lacked social and physical connection. Encounters were perceived as impersonal and rushed, with limited cultural sensitivity. Finally, privacy and security concerns were prominent. Patients feared breaches of confidentiality through session recordings, unauthorized presence of others, and potential cybersecurity risks.

Discussion: While the findings of this study are similar to many studies, this study provided a deeper insights on barriers to TC adoption among patients utilising the qualitative approach. One of the unique findings that is rarely reported in the literature but found in this study was the lack of awareness and understanding of what is TC among patients. This indicates that there is a need to improve patient literacy about TC services. The finding also pointed that there is a need to improve TC workflow integration, train clinicians on empathetic virtual communication, and enhance privacy for TC service.

Conclusion: Low TC uptake in primary care stems from inadequate patient awareness, service process gaps, diminished interpersonal connection, and privacy concerns. Addressing these barriers holistically is essential for effective and equitable TC adoption.

ID 64- Two Years Later: From Adoption to Acceptance – The Evolution of Telemedicine Use and Physician Satisfaction in Family Medicine in Pomurje, Slovenia

Staša VODIČKA

Department Of Family Medicine, Faculty Of Medicine, University Of Maribor, Slovenia, Murska Sobota, Slovénie

Context: Telemedicine was promptly integrated into primary care during the COVID-19 pandemic, but initial implementation was patchy and inconsistent. Since 2024, it has been legally obligatory to use national eHealth platforms in Slovenian family medicine. Collectively, they make up the digital backbone of communication and documentation, integrating telemedicine features as a core component of day-to-day clinical work. This study presents a two-year follow-up of telemedicine adoption and satisfaction among family doctors in the Pomurje region, which was initially surveyed in 2023.

Objectives: In order to compare physician satisfaction and telemedicine adoption in 2025 with that of 2023, as well as indicate which areas of digital practice became better after legal integration.

Methods: A repeated cross-sectional survey was conducted among family doctors in Pomurje in 2023 (N = 105) and 2025 (N = 100). The same questionnaires were employed, measuring telemedicine adoption (yes/no) and 15 satisfaction statements on a 7-point Likert scale (1 = strongly disagree, 7 = strongly agree). PSPP was utilized for descriptive statistics as well as for paired comparisons (McNemar, paired-samples t, Wilcoxon tests).

Results: Telemedicine use increased from 82% in 2023 to 100% in 2025 ($\chi^2(1) = 23.0$, $p < 0.001$). Out of 105 participants, 23 recently adopted telemedicine, and no participants stopped its use. Mean overall satisfaction improved from 4.68 ± 1.96 to 5.13 ± 1.58 ($p < 0.05$). Most notable increases were for perceived work quality (4.05 → 4.63), pleasure in use of digital tools (4.14 → 4.63), and patient accessibility (5.11 → 5.57). No negative changes were noted across items.

Discussion: The results indicate a shift from selective adoption to widespread, stable implementation of telemedicine in everyday family medicine practice. Increased satisfaction implies increasing confidence and normalization of workflows at a digital level. Ongoing concerns relate to usability and retaining patient-centred communication in digital care.

Conclusion: Telemedicine had come a long way in Pomurje, developing by 2025 from a crisis innovation to a regular, legally sanctioned practice. Doctors expressed increased satisfaction as well as benefits, changing from being forced to being accepting. Future attention needs to shift from implementation towards refinement, fairness, and retaining humanism in digital healthcare.

ID 2012- Problems coordinating and accessing primary care for attached and unattached patients in a pandemic year: findings from the patient survey

Abraham MUNENE [(1)], Emily MARSHALL [(1)] , Mylaine BRETON [(2)], Veronique DESLAURIERS [(2)], Maria MATHEWS [(3)], Michael GREEN [(4)], Jennifer ISENOR [(1)]

(1) Dalhousie University, Halifax, Canada
(2) Sherbrooke University, Sherbrooke, Canada
(3) Western University, London, Canada
(4) Northern Ontario School Of Medicine, Sudbury, Canada

Context: Fifteen percent of XXX patients lack access to regular primary care providers (PCP) i.e., family physicians or nurse practitioners.These patients are referred to as unattached patients. PCPs are the first point of contact patients have with the healthcare system. Primary care is a crucial component of the healthcare system and is important to providing the first line of care, prevention of illness and mortality, and referral to specialists. Attachment to a PCP is associated with better health outcomes such as timely treatment, better management of chronic illness, lower likelihood of unmet health needs or

undiagnosed conditions, and better health outcomes.

Objectives: To delineate patients' attachment status, ways of gaining attachment, time to attachment, preferences for, and attachment to different PCP types.

Methods: We conducted a cross-sectional survey with patients across three XXX provinces, XXX, XXX, and XXX. The survey was conducted online over a two-week period in November 2025. Descriptive statistics were conducted on key variables including patient attachment status, provider attachment type, ways of finding a provider, and time to attachment.

Results: The survey was sent to 3202 patients with 2571 patients completing the survey. Approximately 25%, 15%, and 32% of patients did not currently have a PCP in XXX, XXX, and XXX, respectively. Nearly 86%, 95%, and 93% of attached patients were attached to a family physician. The top way of getting connected to PCPs was through family members in XXX and XXX, and through Guichet d'accès à un médecin de famille (GAMF, the patient registry) in XXX. Approximately 39%, 56%, and 35% of patients waited less than one year to get attached to a PCP in XXX, XXX, and XXX.

Discussion: Early findings suggest differences in both the proportion of attached patients and the rates of attachment in the three provinces. Family doctors are also the main provider type patients are attached to, and there is a preference for attachment to a family doctor.

Conclusion: The findings from this cross-provincial survey will be used to inform research, policy, and practice with respect to improving access to primary care for patients.

ID 1817- Geographical coverage analysis of primary care centers operating with patient panels

Mehmet AKMAN, Furkan ALTINÖZEN, Pemra ÜNALAN

Marmara University School Of Medicine Department Of Family Medicine, Istanbul, Türkiye

Context: Population is generally defined as a community of people living in the same geographical area, particularly in the context of community-oriented primary care. However, in many countries, including Türkiye, GP's provide services to the population registered on their patient lists.

Objectives: This study aimed to examine the geographical coverage of Family Health Centers operating with patient lists in the districts of Tuzla, Sultanbeyli, and Pendik in XXX.

Methods: This quantitative, descriptive, and cross-sectional study was conducted in six Primary Care Centers (Family Health Center -FHC) selected through convenience sampling, with two centers from each district. With a 99% confidence level and an unknown population size, the required sample size was calculated as 664. Assuming a 40% non-response rate, 928 individuals were planned to be included, corresponding to 155 participants per center. Adults aged ≥18 years registered at the FHCs were randomly selected. Selected individuals were contacted by phone, and those who agreed to participate and signed the consent form completed a pre-designed questionnaire.

Results: A total of 598 participants completed the study. Of these, 51% were women and 49% were men, with a mean age of 40.6 .The most common reasons for FHC visits were upper respiratory infections or minor health problems (40.1%) and prescription renewal (30.1%). The proportion of participants living within 0–500 meters of their FHC was 46%, and those living within 0–1000 meters reached 77.9%. Overall, 90.4% lived within 2000 meters. A total of 76.1% accessed the FHC on foot, while 23.9% used a vehicle. Participants residing within 0–500 meters applied to the FHC more frequently—both within the last 3 months and within the last year.

Discussion: The study shows that in the patient-list–based family medicine service provision, individuals predominantly select FHCs close to their residence, and proximity facilitates access to services.

Conclusion: These findings suggest that geographical coverage can be achieved through patient lists even within community-oriented primary care models.

ID 1629- Spatial disparities in access to general practitioners: longitudinal study of the lived territories of the Centre-Val-de-Loire region in France (2013-2022).

Charlotte DE FONTGALLAND [(1)] , Katerina KONONOVICH [(2)], Frédérique MÉNORET [(3)], Jean-Marc MACÉ [(4)]

(1) Urps Ml Cvdl, Orléans, France
(2) Lirsa-Cnam, Paris, France
(3) Assurance Maladie, Orléans, France
(4) Lirsa, Paris, France

Context: The French health system is marked by a deficiency in medical demography which impacts the management of front-line care (general practitioners, emergency services). The liberal configuration of this health system allows any doctor to choose their place of exercise, which strengthens the territorial inequalities of access to care linked to both the aging of the population and the retirements of non-replaced practitioners.

Objectives: In response to the deterioration of the density of general practitioners, we sought to understand whether patients were turning to other forms of front-line care (emergency services, teleconsultation platform, out-of-region consultations, etc.) and to assess the impact of these developments on the health of populations.

Methods: This research is based on a longitudinal study in the 385 "territories experienced by general practitioners" identified in the Centre-Val-de-Loire region between 2013 and 2022. Healthcare data from the SNDS databases SNIIRAM and DCIRS-PMSI (general practice procedures and services, emergency department visits, teleconsultations, unscheduled care), and epidemiological data from Santé publique France (Géodes), are analyzed using multivariate methods (Comparative Consumption Index, Principal Component Analysis, and Hierarchical Agglomerative Clustering).

Results: The results show a significant drop in ten years of consultations with general practitioners at the regional level (-20 %). At the same time, emergencies without hospitalisation are barely increasing (+0.1%), consultations within and outside the region have fallen sharply (-2 million consultations, i.e. -52%), and we can see a timid appearance of teleconsultations. Only 10% of the shortfall in consultations in offset by emergencies and teleconsultations, with strong infra regional disparities.

Discussion: These spatial inequalities reflect the systemic effect linked not only to the decrease in the effective density of general practitioners, but also a pejoration of the state of health of the populations of certain "territories experienced" by the mechanism of renunciation of care of first lines by the different most disadvantaged populations.

Conclusion: This shows, firstly, that the choice of territory, the geographical divisions used, change the vision of these inequalities, and secondly the importance for public policy of equipping itself with territorial observation tools that are as close to the reality as possible, corresponding to the care practices of patients and carers.

ID 562- Implementation of territorial pediatric care teams to ensure equity and quality in Catalonia

Gemma RICÓS FURIÓ [(1)], Elisabet DESCALS SINGLA [(1)] , Rafael RUIZ RIERA [(2)], Aina OLLÉ VILA [(2)], Anna REÑÉ REÑÉ [(1)], Aniol MARULL BORRELL [(2)], Eulàlia FORNIES CODINA [(2)], Albert SIURANA SAUMELL [(2)], Anna ANDRES [(1)], Albert BOADA VALMASEDA [(2)]

(1) Institut Català De La Salut, Barcelona, Espagne
(2) Departament De Salut, Barcelona, Espagne

Context: Catalonia has a recognized pediatric primary care model. However, social, demographic, and health changes, together with territorial inequalities and coordination gaps, make it

necessary to redefine the model to guarantee equitable and comprehensive care. Scientific evidence confirms that care provided by pediatricians and specialized pediatric nurses improves child health outcomes. Objective is to ensure integrated, coordinated, accessible, and high-quality pediatric care across Catalonia through the progressive implementation of Territorial Pediatric Care Teams (ETAP), reducing disparities, ensuring homogeneous access to services, and achieving improved health outcomes.

Methods: A quantitative and qualitative analysis of the current situation was conducted, including territorial distribution, vacant positions, retirement forecasts, ETAP implementation status, and care indicators. Based on these results, a strategic plan was defined to include team creation and expansion, service portfolio, resource allocation, and a monitoring system based on indicators.

Originality: The ETAP project is innovative because it introduces a territorial, integrated pediatric care model with multidisciplinary teams that ensure equity and quality in child health. Unlike other models, it incorporates a data-driven strategy for resource plann

Lessons learned and future implication: Key lessons learned include the importance of collaborative leadership, clear communication with professionals and families, and technological adaptation to improve accessibility. The future plan aims to expand coverage from 36% to 55% during the first se

Discussion: Implementation faces challenges such as institutional recognition, infrastructure adequacy, resistance to change, technological limitations, and public acceptance. Strategies include collaborative leadership, clear communication, and active involvement of professionals and families. The project is based on principles guiding ETAP organization: professional autonomy for responsible clinical decisions; territorial equity to ensure equal access to services, prevention, and scientific innovation; and cohesion to foster interprofessional collaboration, resource solidarity, and an integrated vision of child health.

Conclusion: ETAP deployment is a strategic commitment to consolidate a territorial, integrated, and sustainable pediatric care model that guarantees equity and quality in health.

ID 363- Qualitative survey of patients' perceptions of general practitioner accessibility

Dominique HENRION

Université De Namur, Namur, Belgique

Context: A detailed understanding of accessibility to healthcare is vital to support healthcare professionals, universities and political decision-makers in developing sustainable healthcare provision in Belgium. Accessibility to healthcare is a widely debated concept, often in binary terms: financial accessibility and/or the density of doctors per population. Unfortunately, the issue is much more complex and subjective.A detailed understanding of accessibility to healthcare is vital to support healthcare professionals, universities and political decision-makers in developing sustainable healthcare provision in Wallonia. Accessibility to healthcare is a widely debated concept, often in binary terms: financial accessibility and/or the density of doctors per population. Unfortunately, the issue is much more complex and subjective.

Objectives: This studie aim is to identify whether there are any difficulties in accessing GPs, potential accessibility problems and geographical variations. The aim is also to identify the predominant independent variables (distance, travel time, other factors) impacting on accessibility difficulties.

Methods: We surveyed a panel of Belgian citizens through the "The Social Study" project call: the TSS panel comprises a representative group of 5,000 Belgian citizens aged 16 and over, randomly selected from the national register. The scientific committee selected 1,042 panelists residing in the Walloon Region. The response rate was 81.77% (n=852). Data collection took place between December 2, 2024, and February 4, 2025, using either an electronic or paper questionnaire to avoid technological bias. After cleaning the database, 801 responses were used (76.87% of the panel).

Results: Approximately 25% of panelists reported having difficulty finding a general practitioner. The reasons are varied. For example, about 6% postpone an appointment due to cost. Patients whose health

requires a home visit have more difficulty finding a general practitioner.

Discussion: This is an exploratory study preceding a qualitative study.

Conclusion: Our study allows us, on the one hand, to establish an observation on the difficulties of access to general practitioners in the French-speaking part of Belgium and, on the other hand, to establish hypotheses on the causes of these difficulties;

ID 284- Finding a GP in a healthcare desert: assessing a territorial access initiative

Alexis VANDEVENTER, Clélia INGUIMBERT

Faculté De Médecine De Montpellier-Nîmes Dumg Montpellier Nîmes, Montpellier Nimes, France

Context: Several European regions face persistent difficulties in ensuring access to primary care due to GP shortages, demographic pressures, and increasing care needs. Territorial health organisations have been mandated to improve population coverage, particularly by facilitating access to a regular general practitioner (GP). This study assessed the implementation and perceived effectiveness of a structured access initiative targeting individuals without a GP.

Objectives: To assess the acceptability, and perceived feasibility of a territorial scheme designed to secure a regular GP for patients lacking one.

Methods: A cross-sectional study was conducted among patients and GPs participating in the initiative. Participants completed a structured satisfaction survey assessing accessibility, clarity of information, perceived barriers, and continuity of care. Descriptive analyses were performed.

Results: Among 104 eligible patients, 43 participated (41%). Most were women (63%) and reported long-term conditions (84%). Despite 65% requiring assistance to complete the request form, most found the procedure easy. Satisfaction with initial contact was universal, and 86% reported timely outreach. Appointment timeliness (76% satisfied) and practice distance (85% satisfied) were positively rated. Continuity was high: 86% were still followed by the assigned GP, who had become their regular doctor in most cases. Recommendation intention was strong (74%). Fourteen of 44 participating GPs responded (32%). Most worked in multidisciplinary practices (64%) and judged the information provided as clear or sufficient (71%). Most integrated only a small number of patients. Half reported organisational adjustments, mainly longer consultations. Missing clinical information was frequently mentioned as a barrier. Nonetheless, 86% would participate again, and 93% would recommend the scheme.

Discussion: Findings suggest that a structured territorial approach can enhance access to a regular GP for patients without one, with high levels of satisfaction and sustained continuity of care. GP engagement was positive, although operational constraints, particularly incomplete information transfer and increased workload, may limit scalability. Strengthening clinical information flow and organisational support appears essential for sustainable implementation. Such initiatives may constitute a valuable contribution to mitigating primary care shortages and promoting equitable access in underserved areas.

Conclusion: The scheme demonstrates high acceptability and offers a promising model for improving access to primary care in contexts of limited GP availability.

Transgender's care

ID 2207- Assessments of healthcare services received and healthcare professionals encountered by transgender individuals living in Türkiye

Fatih Erkan AKAY [1] , F. Gülsüm ÖNAL [2], Pemra CÖBEK UNALAN [1]

(1) Department Of Family Medicine, Marmara University School Of Medicine, Istanbul, Türkiye
(2) Department Of Deontological Ethics, Trakya University School Of Medicine, Edirne, Türkiye

Context: Individuals belonging to minority groups in gender and sexual orientation experience poorer health outcomes, largely due to barriers in accessing and discrimination in receiving proper healthcare. A key step in reducing stigma was the removal of the term homosexuality as a disease from the Diagnostic and Statistical Manual of Mental Disorders in 1973; however, healthcare professionals' attitudes toward transgender individuals continue to influence the quality of care received by them.

Objectives: The aim of this study is to assess the thoughts of the transgender individuals living in Türkiye about the healthcare they received and the healthcare professionals that they encountered.

Methods: This descriptive study was conducted using purposive sampling and included 39 transgender participants. Data were collected through a structured questionnaire consisting of 21 questions, 4 of which were open-ended. The questionnaire assessed participants' demographic characteristics, gender identity, experiences with healthcare professionals, and perceived and desired attitudes from healthcare workers. Participants were recruited through the transgender-supporting networks and NGOs. Descriptive statistics are analyzed by SPSS.

Results: Of the total, 25 were identified as trans women, 13 as trans men, and one as intersex. The majority of participants (n=22) were currently undergoing gender transition, while nine had not yet initiated transition medically and eight reported having completed the process. Notably, 21 participants expressed dissatisfaction with the healthcare they received during their transition. Nineteen participants reported that the accessibility to general healthcare services was affected negatively by their comfort. Participants frequently described healthcare professionals' attitudes as inattentive, careless, hostile, dismissive, or characterized by providing exaggerated reassurance while disregarding their specific concerns. Nonetheless, 24 of the individuals thought that their identity wasn't an issue in the general healthcare they received.

Discussion: These findings indicate persistent variability in healthcare experiences among transgender individuals, reflecting ongoing gaps in healthcare professionals' knowledge, attitude, and inclusive clinical practices that will affect patient comfort, satisfaction, and equity in healthcare delivery.

Conclusion: Transgender individuals face notable challenges in healthcare settings, highlighting their need for awareness, inclusive practices, and particularly training among healthcare professionals to promote equitable and respectful care.

ID 2008- New-onset chronic pelvic pain after initiation of gender-affirming hormone therapy among transmasculine individuals: an exploratory qualitative survey.

Blanca BERMUDO DE MATEO [1] , Max CRESSENT [2], Saraeve GRAHAM LONGSWORTH [1], Katia GHERAIEB [3], Camille BOYER [1], Alix ISAAC [3]

(1) Université Grenoble Alpes, Grenoble, France
(2) Rita (trans Community Health Association), Grenoble, France
(3) Planning Familial De L'isère, Grenoble, France

Context: New-onset chronic pelvic pain (CPP) has been reported in transmasculine individuals after initiation of testosterone gender-affirming hormone therapy (GAHT). Its physiopathology, prevalence and link to GAHT remain unknown. Trans people have poorer health status compared to the general population and face numerous barriers to accessing healthcare.

Objectives: The objectives of this study were to describe CPP in this population, its impacts, and to identify barriers and facilitators to healthcare.

Methods: A qualitative observational study was conducted between September 2024 and October

2025 in Grenoble (France). Individual, semi-structured, face-to-face interviews were conducted. Participants were adult transmasculine individuals experiencing new-onset or modified CPP after initiation of GAHT. Interviews were transcribed. Emerging codes subthemes, and themes were identified according to reflexive thematic analysis.

Results: Twelve participants were interviewed. In most of the cases, dysmenorrhea disappeared or improved with GAHT, but new new-onset CPP subsequently appeared. This CPP was frequently triggered by orgasm. CPP had a strong impact on mental health, social, sexual, and professional life. In the healthcare system, participants faced multiple discriminations and neglects. Trans community health was very important for participants but could not substitute formal health services. Younger participants trusted more medical institution suggesting potential ongoing structural changes.

Discussion: New-onset CPP after initiation of GAHT in transmasculine individuals may be related to pelvic floor dysfunction, to endometriosis and/or to central and peripheral sensitization mechanisms. Intersectional, biopsychosocial and trauma-informed care approaches are needed to understand the experience of CPP in this population.

Conclusion: This study describes CPP that transmasculine individuals may suffer from. It also identifies important healthcare issues which may help to ensure quality care for trans people. Further studies evaluating CPP prevalence and physiopathology in transmasculine individuals are needed.

ID 1835- The One That Got Away: Unregulated Hormone Use in a Transgender Adolescent with Psychiatric Comorbidities

Stephanie Nicole REYES

University Of The Philippines-Philippine General Hospital, Manila, Philippines

Context: Family Medicine Practitioners often serve as the first contact for most of the population navigating complex psychosocial and medical needs. This role places family physicians at the forefront of identifying health risks among vulnerable patients. Such patients may engage in high risk behaviors, including unsupervised ingestion or use of medications or supplements. A high index of suspicion for toxicologic or iatrogenic causes is essential when patients present with unexplained symptoms or laboratory abnormalities. This case emphasizes the importance of comprehensive history-taking, psychosocial assessment, and vigilance for potential toxicants in primary care settings.

Methods: An 18-year-old transgender male (assigned female at birth) with bipolar disorder and major depressive disorder presented with exacerbation of psychiatric symptoms and deranged laboratory values following prolonged, unsupervised use of testosterone enanthate as gender transitioning therapy. His clinical manifestations manifested both the acute and chronic toxicities of testosterone. The patient was assessed through comprehensive medical and psychiatric evaluation, underwent appropriate diagnostic testing, and was managed primarily with symptomatic and supportive care. A key strength of this case is that it highlights unsupervised substance exposure in an adolescent with psychiatric comorbidities and provides practical implications for family medicine practice. Long-term outcomes could not be assessed due to unavailability of follow-up after the patient's premature departure from the hospital.

Originality: This case contributes to limited literature describing testosterone toxicity in transgender adolescents, particularly in those with pre-existing psychiatric disorders. It also illustrates unsupervised access and prolonged exposure to testosterone.

Lessons learned and future implication: Family physicians must maintain vigilance for concealed or undisclosed exposures that may contribute to a patient's presentation. This requires careful, comprehensive history taking and physical

examination. It also reinforces the need for integrated ment

Discussion: This case reflects structural gaps in access to supervised gender-affirming care that can drive patients toward self-medication. For family physicians, the case emphasizes the need for an open diagnostic approach when clinical findings appear disproportionate or atypical.

Conclusion: Family medicine physicians have a critical role in identifying toxicologic risks, protecting vulnerable populations, and advocating for safeguards within primary care systems.

ID 346- "Patient's interest must come first": XXX general practitioners' experience of initiating testosterone therapy for transgender people against national regulations

Alex WEIL [(1)] , Emmanuel ALLORY [(1)], Julie GILLES DE LA LONDE [(2)], Armelle GRANGÉ-CABANE [(2)]

(1) Université De Rennes, Rennes, France
(2) Université Paris Cité, Paris, France

Context: General practitioners (GPs) increasingly encounter transgender and gender diverse (TGD) individuals seeking gender-affirming care. But access to this care remains limited, despite evidence that it improves the well-being of this population, more at-risk for adverse health outcomes. In XXX, it is forbidden for GPs to write the initial prescription for testosterone. Some GPs choose to do it nonetheless, to help TGD patients who have difficulties accessing gender-affirming hormonal therapy (GAHT).

Objectives: This study aimed to explore the experience of XXX GPs initiating testosterone therapy for TGD patients, against current regulations, and the meaning it had for them.

Methods: This qualitative study was conducted via in-depth semi-structured interviews with nine XXX testosterone-initiating GPs recruited using purposive sampling, analyzed following the phenomenological interpretative analysis method.

Results: These GPs experienced this practice as an ethical imperative and a professional duty, as a social commitment for justice and equity, and for some, as an activist and political form of medical care. They felt responsible to help TGD people access care, and chose to transgress, in the name of their patients' interest, regulatory restrictions that they deemed illegitimate. Despite difficulties or threats, they persevered, building networks with colleagues and TGD people. They experienced a more horizontal doctor/patient relationship, and recognized the value of community expertise. Indeed, they aimed to exchange knowledge and share power with patients treated as partners, at the individual and systemic levels. They focused on a patient-centered approach, to co-build the best possible care for every TGD person: to them, this was the heart of what being a GP means.

Discussion: Our findings show the participants' answers to a pressing question, internationally: where to stand, as GPs, committed to improving patients' health and quality of life while relying on scientific evidence, when these guiding ethical and deontological principles clash with current regulations, usual protocols, or political controversies ?

Conclusion: These doctors' choice to accompany patients' self-determination sometimes put them under duress, given their medico-legal liability in the current system. National and international guidelines regarding GPs' role in transgender care are evolving. If XXX regulations changed to better acknowledge GPs' GAHT prescriptions, doctors and patients could feel safer.

ID 1133- The role of the family doctor in transgender individual healthcare – a clinical report

Rita AMARAL, Isabel GRAÇA, Ana Sofia OLIVEIRA, Mariana NEVES

Usf Aníbal Cunha, Uls Santo António, Porto, Portugal

Context: The follow up of a transgender person is a challenge to the primary care practice, with technical, ethical and empathy growing demands. The family doctor has a key role to ensure continuity, proximity, and coordination of care.

Methods: We present a case of a transgender individual with autism spectrum disorder. He had a family doctor in another unit, with whom he felt no proximity. During the transition, he had nurse assistance in our unit and, after developing a close relation with the nurse, he asked for a medical appointment. His doubts were about contraception, sexually transmitted infections and safe sexual practices, and he felt he had no time and empathy from the hospital doctors, often feeling insecure and ashamed to express his doubts. We developed a relationship based on empathy and security, clarifying his doubts and helping with decision making. Contacts were also established with other doctors, namely endocrinology, respecting the individual choices and preferred timing in the transition process.

Originality: There is a significant gap in clinical guidance for caring for transgender or gender-diverse individuals with a neurodiverse condition. Existing guidelines lack detailed, practical recommendations tailored to this intersection, highlighting the need for m

Lessons learned and future implication: This case highlights the need for caution in assuming uniform care pathways and highlights the need for additional training and multidisciplinary collaboration to address the unique needs of transgender individuals.

Discussion: This case highlights the importance of the family doctor as a care coordinator, promoting access, preventing disruptions in follow-up, and reducing risk factors associated with social exclusion.

Conclusion: The family doctor plays a central and irreplaceable role in the care of transgender individuals, providing continuous, integrated, and personalized care that is fundamental to the bio-psycho-social well-being of this population.

ID 815- Gender-Related Equipment and Primary Care: Uses, effects, and clinical perspectives from a qualitative study in Belgium. Key words : Transgender Persons, Gender Identity, Health Services for Transgender Persons, Primary Health Care, Health Services Access

Jean COËRS [(1)] , Vincent HUBERLAND [(1)], Aurore DUFRASNE [(2)]

(1) Université Libre De Bruxelles (ulb), Bruxelles, Belgique
(2) Genres Pluriels Asbl, Bruxelles, Belgique

Context: Transgender patients frequently use gender-affirming equipment to support bodily comfort, mental health, and gender expression. Despite their widespread use and documented benefits, these items are rarely addressed in primary care, where lack of training and fragmented care pathways leave patients navigating access and safety alone. Understanding these practices is essential for developing inclusive care for transgender populations.

Objectives: This study explored how transgender patients access and use gender-affirming equipment and examined their perceived benefits and limitations. It also explored patients' views on how, when, and why primary care clinicians should address these items in clinical encounters.

Methods: A qualitative study was conducted through semi-structured interviews with transgender adults recruited from primary care and community settings. Transcripts were analysed using continuous thematic analysis to identify patterns in access, use, and support needs regarding gender-affirming equipment. Ethical approval was obtained from an Ethics Committee.

Results: Participants reported that gender-affirming equipment provided essential support for bodily comfort, psychological wellbeing, and social functioning. Barriers included physical discomfort, safety concerns, high costs, limited availability in Belgium, and the lack of opportunities to try items before purchase. Participants emphasised the absence of medical guidance in primary care and the fragmentation of trans-specific care pathways, leading them to rely primarily on peers and community networks for trustworthy information. Many described these items as functioning as a form of healthcare, particularly when access to gender-affirming medical care was delayed or restricted.

Discussion: The study highlights a critical gap in primary care: despite their clear benefits, gender-affirming equipment remains largely unaddressed by clinicians, leaving patients to navigate safety and access alone. These findings mirror existing literature on binding and tucking and underline the need for primary care providers to engage with these practices as legitimate components of person-centred care, especially when medical transition options are delayed or inaccessible.

Conclusion: Gender-affirming equipment plays a meaningful role in the wellbeing and daily lives of transgender patients, yet remains largely absent from clinical practice in primary care. Recognising and addressing these items in primary care could improve safety, accessibility, and patient-centred support for transgender people.

Ultrasound Cases & Training

ID 2043- the Echo-anatomy of the breast according to the lobar approach with ducto-radial technic

Dominique AMY

Cffe /eesf, Aix En Provence, France

Context: Point of care ultrasound (POCUS)is a valuable tool in family medecine and ambulatory healthcare for evaluating sympomatic breast conditions. The extremely frequent problem of a 'lump in a breast' can be solved in a quick, simple way, as minimally aggressive as possible and not irradiating. We propose the technique of anatomical analysis of the breast lobes using ducto-radial ultrasound scans easily assimilable by the general practitioner (GP)

Methods: From histological correlations and radial echographic sections of the breast lobes, it is possible to study the mammary epithelial structures that will be affected by specific mamieres by pathological processes. These sections are codified, interpretable by all, they will not be operative-dependent but only anatomical-dependent.

Originality: the physiological or pathological variations identified at a precose stage allow the GP to classify patients in a reassuring category or in an at-risk category requiring additional investigations by specialists. the GP will no longer describe layers of fi

Conclusion: In his POCUS approach, the general surgeon needs a diagnostic tool and a reliable ultrasound methodology in breast pathology. the new possibilities for acquisition of high-quality ultraportable devices with Doppler mode associated with a specific technique Codified, readable by all, repetitive, non-operative- dependent, will deeply modify the initial approach in breast pathology. The GP is not going to make a precise diagnosis of all lesions. but he will be able to select patients at risk (oriants towards specialized centers of imageris medicale) or reassure as he can the worried patients. He will thus establish a strengthened relationship of doctor-patient trust. It will be easier for him because he was able to understand the anatomy of the breast (lobar approach to his examination) visualize early physiological changes or a pathological state at an initial millimetric stage.

ID 1739- Follow-up of patients hospitalized for sars-cov2 pneumonia: radio-clinical and respiratory function assessment

Aouayeb KHADIJA

Medical Resident, Nabeul, Tunisie

Context: The SARS-CoV-2 infection has led to a global public health crisis. Beyond acute manifestations, SARS-CoV-2 pneumonia is associated with medium- and long-term pulmonary sequelae, commonly referred to as long COVID. These persistent and heterogeneous manifestations represent a major challenge for clinicians and have generated increasing interest in long-term post-COVID follow-up studies.

Objectives: Our objective was to describe the clinical, respiratory function, and radiological evolution of SARS-CoV-2 pneumonia and secondarily, to identify predictive factors for the development of pulmonary fibrosis.

Methods: We conducted a prospective and descriptive study in the pneumology department of Menzel Temim Hospital. We included 70 patients hospitalized for moderate to severe SARS-CoV-2 pneumonia between December 2020 and June 2021. We assessed clinical, respiratory function and radiological evolution at 45 days, three months, and six months after the acute episode. Patients lost to follow-up were not included.

Results: The mean age was 63 years, with a gender ratio of 0.66. Obesity (56%) and blood hypertension (40%) were the most common comorbidities. Clinically, we observed an improvement in dyspnea ($p=0.01$), cough ($p=0.09$), and asthenia ($p=1$) after six months. However, the six-minute walk test showed a reduction in the walking distance ($p<0.001$), and spirometry demonstrated a significant decrease in forced vital capacity ($p=0.01$). The six-month chest CT scan revealed the development of pulmonary fibrosis in nine patients. Predictive factors for pulmonary fibrosis included: the severity of acute pneumonia, the absence of symptoms at discharge, the persistence of asthenia at 45 days, and radiological lesions at three months. In multivariate analysis, only the absence of functional complaints at discharge and the persistence of radiological abnormalities at three months were considered independent predictive factors for pulmonary fibrosis.

Discussion: Persistent respiratory symptoms, functional impairment, and radiological

abnormalities were common after SARS-CoV-2 pneumonia. Dyspnea remained the predominant symptom, while exercise intolerance and reduced lung volumes persisted. Pulmonary fibrosis was associated with initial disease severity and persistent radiological lesions, highlighting the importance of structured long-term follow-up. Early identification of high-risk patients may improve prognosis and management.

Conclusion: Our study shows that SARS-CoV-2 infection can lead to persistent pulmonary sequelae,requiring rigorous follow-up, at least during the first-year post-hospitalization for SARS-CoV-2 pneumonia.

ID 782- Competencies and Clinical Situations of General Practitioners Performing Ultrasound: A Systematic Review of Consensus Studies

Dragos Paul HAGIU [(1)], Fauve FLAMANT [(2)], Valentin BONNARD [(1)], Bastien AUBART [(2)], David DE BANDT [(2)]

(1) Département Médecine Générale,faculté De Médecine Jacques Lisfranc De Saint Etienne,université Jean-Monnet, Saint-Etienne, Saint-Etienne, France
(2) Département De Médecine Générale, Ufr Simone Veil Santé, Université Versailles-Saint-Quentin, Montigny Le Bretonneux, France, Montigny Le Bretonneux, France

Context: Point-of-care ultrasound (POCUS) is experiencing rapid growth in general practice, driven by technological accessibility, expanding clinical applications, and rising expectations for diagnostic precision in primary care. This trend has recently been consolidated by the 2024 WONCA Europe position paper, which affirms POCUS as an emerging core skill for general practitioners (GPs). However, the competencies and clinical situations that should guide GP training remain insufficiently standardized.

Objectives: The objective of this study was to systematically review Delphi and other consensus-based studies to identify the families of clinical situations and the competencies that should underpin ultrasound training for GPs.

Methods: A systematic review of the literature was undertaken according to a predefined protocol registered in PROSPERO (CRD420251160211). The search strategy targeted consensus studies (Delphi, RAND/UCLA, nominal group techniques) related to POCUS in primary care. Searches were conducted in PubMed, Web of Science, and the Cochrane Library. Eligible studies involved GPs, applied a consensus methodology, and addressed competencies, scopes of practice, or training requirements for POCUS use.

Results: Among 182 records, 30 duplicates were removed, 11 full texts were assessed, and 6 studies met inclusion criteria. Across these studies, thematic convergence emerged. All emphasized the value of short, structured, multimodal training combining supervised hands-on practice, clinical application, and ongoing monitoring of image quality. Priority POCUS indications consistently included emergency assessments such as FAST, abdominal examinations including abdominal aortic aneurysm, basic cardiac evaluation for function or effusion, lung ultrasound, and musculoskeletal scans. Competency frameworks described up to 36 validated diagnostic skills, such as detection of abdominal free fluid, bladder assessment, and basic urogenital evaluation, along with image interpretation, clinical integration, and referral decision-making. One framework proposed a five-level progression from equipment handling to image optimization, systematic examination and clinical interpretation. Another curriculum outlined 40 diagnostic examinations across 13 anatomical regions relevant to primary care diagnostics and procedures.

Discussion: Clarifying competencies and clinical indications is essential for structuring POCUS education in general practice and supporting its integration into academic training pathways.

Conclusion: Future studies should investigate how these competency frameworks can be implemented in academic curricula and assess their impact on training effectiveness and patient outcomes.

ID 741- Ultrasound in general practice as perceived by french medical students

Laurent AUBERTIN [1] , Baptiste CHAUVIN [2]

(1) Snecho-Mg, Angers, France
(2) Département Universitaire De Médecine Générale, Ufr Santé, Unirouen ; Snecho-Mg, Rouen, France

Context: Ultrasound has become increasingly important in medicine, particularly in general practice. However, training remains challenging and occurs late in the students' curriculum. This work proposes an analysis of the perception of second-cycle medical students in France regarding its use in general practice and how they consider their own ultrasound training.

Objectives: The primary objective was to assess how second-cycle medical students perceive the use of point-of-care ultrasound in primary care, including their understanding of its role and their interest in its clinical applications. A secondary objective was to explore students' views on the potential integration, format, and relevance of an introductory ultrasound curriculum during the second cycle of medical training.

Methods: The study is based on a qualitative approach through semi-structured interviews, targeting fourth- to sixth-year medical students who observed POCUS (Point-of-Care Ultrasound) during their internships in general medicine. Recruitment took place in 33 medical faculties across metropolitan France. The collected data were coded manually and an inductive thematic approach was used.

Results: Students expressed strong curiosity about ultrasound as a clinical learning tool but also reported apprehension related to technical aspects and limited anatomical knowledge. They identified several barriers, including insufficient hands-on training and limited access to adequate supervision.

Discussion: Findings suggest that ultrasound can serve as a meaningful pedagogical tool, reinforcing students' clinical reasoning, autonomy, and understanding of patient pathways. It also appears to enhance relational skills, particularly in the physician-patient interaction. Students showed a clear interest in structured, early ultrasound exposure during the second cycle. They identify clear barriers—limited time, resources, and late curricular integration—but also propose feasible solutions for early implementation. These findings suggest that introducing basic ultrasound training during the second cycle could meaningfully support professional development and align medical education with evolving primary care practice.

Conclusion: Ultrasound is seen as an essential tool for the training of future physicians. To maximize its benefits, it is crucial to improve training, increase access to equipment, and adapt clinical practices to current technological advancements. This could not only enhance patient diagnosis and follow-up but also optimize the efficiency of the healthcare system.

ID 1141- Primary diagnostics of cardiac ATTR amyloidosis using Point-of-care ultrasound (POCUS) evaluation

Jozef REPOVSKY [1] , Anna REPOVSKA [2]

(1) Society Of General Practicioners Of Slovakia, Trebisov, Slovaquie
(2) Society Of General Practicioners Of Slovakia - Trebisov (Slovakia), Trebisov, Slovaquie

Context: A 71-year-old woman with no significant medical history presented to a general practitioner with progressive fatigue, exertional dyspnea, and marked exhaustion when climbing stairs. Her prior history included only orthostatic hypotension and a pre-fatigue state. Physical examination and laboratory testing were performed. ECG showed sinus rhythm with low QRS voltages. Point-of-care ultrasound (POCUS) emerged as the pivotal diagnostic modality raising suspicion for transthyretin (ATTR) cardiac amyloidosis.

Methods: The diagnostic pathway relied on standard modalities accessible to general practitioners, including physical examination, laboratory tests, ECG, and POCUS. In this case, POCUS was the key tool that redirected the diagnostic reasoning toward a specific cardiac etiology, prompting timely referral and confirmatory testing.

Originality: This case demonstrates the strong diagnostic value of POCUS in primary care,

especially in patients with nonspecific symptoms where traditional modalities (including ECG and basic labs) may provide only limited clues. It represents the first documented ca

Lessons learned and future implication: Point-of-care ultrasound should be considered a standardized part of the evaluation of patients with unexplained dyspnea, fatigue, or signs of possible cardiac dysfunction. Early use of POCUS can significantly accelerate diagnostic accuracy and guide appr

Discussion: How are POCUS methods utilized in primary care settings in your country? We can evaluate the improvement of provided medical care in Slovakia since implementing POCUS.

Conclusion: In 2024, POCUS has become an accessible and impactful tool in Slovak general practice. Its integration enhances diagnostic precision, allows earlier detection of serious cardiac diseases such as ATTR amyloidosis, and supports timely therapeutic decisions—ultimately improving patient outcomes, as demonstrated in this case report.

ID 309- Scoping review about echography teaching modalities during residency and medicine study with the objective of creating a teaching class during general practitioner residency.

Aurélien LETELLIER, Anthony DROBECQ, Isabella MARINO, Baptiste CHAUVIN

Rouen, Rouen, France

Context: Ultrasound is increasingly used in clinical practice thanks to its non-irradiating nature and rapid diagnostic capability. General practice residents encounter it regularly, particularly during rotations in emergency medicine and obstetrics-gynecology. However, despite its widespread use, no standardized training exists for an examination that remains highly operator-dependent.

Objectives: The aim of this study was to conduct an international literature review to describe existing educational approaches and propose the foundation for a future training module adapted to general practice residency

Methods: A scoping review of the literature was conducted. Included were short training programs (≤ 2 weeks or ≤ 40 hours) intended for medical students and general practice residents, as well as residents in obstetrics-gynecology and emergency medicine, as these were considered transferable. The fields covered abdominal-pelvic, gynecologic, lung, skin, and targeted venous ultrasound, along with simulator-based training. Effectiveness was assessed using OSAUS criteria (indication, equipment handling, image optimization, systematic examination, interpretation, reporting, and clinical decision-making) and participants' perceived competence.

Results: Fifty-six studies were included. Training relied mainly on expert tutoring, peer-to-peer teaching, e-learning, and simulators. All programs could be completed within a timeframe compatible with medical training. They showed significant improvement in objective skills and perceived competence. Simulators, particularly in obstetrics-gynecology, helped learners acquire psychomotor skills in a safe and ethical environment.

Discussion: This review highlights the effectiveness of short, multimodal training programs for acquiring basic ultrasound skills.

Conclusion: A module combining self-directed learning, supervised peer practice, and on-site clinical application—especially in emergency and obstetrics-gynecology rotations—appears feasible.

ID 259- Persistent adenopathy: Highlighting the crucial role of correlating clinical knowledge with ultrasound examination in primary care.

Andrea BALBARINI

Ausl Mo, Lama Mocogno, Italie

Context: Persistent lymphadenopathy poses a diagnostic challenge in Family Medicine because clinical signs alone poorly differentiate benign from malignant nodes. Point-of-care ultrasound (POCUS) is the preferred non-invasive tool, assessing criteria such as shape, size, hilum visibility, echogenicity, and vascularization. In Italy, general practitioners (GPs) cannot prescribe urgent ultrasounds for suspected malignancy, making POCUS particularly important—especially in rural areas—to support early triage. However, ultrasound interpretation without adequate correlation to clinical context may contribute to diagnostic delays.

Methods: We present a clinical case from rural primary care describing the diagnostic journey of persistent adenopathy, highlighting the interplay between clinical evaluation, POCUS findings, specialist referral, and advanced imaging.

Originality: This case illustrates how seemingly reactive ultrasound findings may mask underlying malignancy, and how system-level barriers can delay definitive diagnosis. It emphasizes the need for integrated clinical–ultrasound assessment and improved access to urge

Lessons learned and future implication: Persistent lymphadenopathy warrants close follow-up even when ultrasound features appear benign. Combining POCUS with a structured reassessment pathway could help GPs identify red flags earlier. Policy changes allowing GPs to request urgent diagnostic ima

Discussion: In May 2024, Tatiana, 30 years old, presented to the emergency department with painful right cervical and axillary lymphadenopathy after razor-related skin irritation and self-administered antibiotics. Diagnosed with bacterial lymphangitis, she received amoxicillin/clavulanic acid. By July, her symptoms persisted. Her GP noted multiple painful, firm lymph nodes; POCUS showed enlarged reactive nodes with atypical features. A specialist ultrasound again described them as reactive, and she was treated for presumed viral lymphangitis with prednisone. After 20 days without improvement, she returned to her GP. Attempts to secure further specialist assessment were delayed until referral to a third-level hospital, where on November 5, 2024, she was diagnosed with metastatic melanoma. This illustrates how inconclusive ultrasound findings and limited access to urgent imaging can prolong the diagnostic process.

Conclusion: Ultrasound is indispensable in evaluating lymphadenopathy, but its findings must be interpreted within the full clinical picture. Strengthening POCUS use and improving access to urgent imaging are essential to reduce diagnostic delays in primary care.

Ultrasound Use and Indications

ID 1551- Assessment of the Use of Echography in Primary Care: Gains in consultation Length, Post-Consultation Recommendations, and Additional Examinations

Francis PELLET

Cffe-Nimes, Les Vans, France

Context: The integration of ultrasound (echography) into primary care has emerged as a promising innovation to enhance diagnostic accuracy, reduces unnecessary additional examinations, and improves patient-doctor trust.

Objectives: This study evaluates the impact of echography on consultation lenght, post-consultation recommendations, and the need for additional examinations.

Methods: A multicentric prospective survey was conducted in the Drôme-Ardèche region of Southern France, involving 18 general practitioners, 9 in the echoclinic group (ECG) and 9 in the stethoclinic group (SCG).The ECG received a 3 day training program on the use of the V-Scan Extend Dual Dicom Ultrasound device. A total of 166 patients were included, with 124 in the ECG and 42 in the SCG. Eight clinical scenarios were evaluated, focusiong on consultation lenght, the number of

additional examinations required, and the alignement between doctor's recommendations and patients' subsequent actions.

Results: The average consultation lenght was 17,5 minutes in both groups, indicating that the use of echography did not prolong consultations. The ECG demonstrated a higher rate of agreement (83%) between doctors' recommandations and patients' actions compared to the SCG (69%). The use of echography reduced the need for additional examinations in 65%of cases, compared to 29% in the SCG. It suggests that echography enhances diagnostic precision and strengthens the patient-doctor relatioship.

Discussion: The study highlights echography to streamline primary care by reducing diagnostic tests and improving patient adherence to medical advice. The abscence of increased consultation time adresses a common concern. Furthermore, the integration of echographyinfo medical training could foster greater confidence and competence among general practitioners, ultimately leading to better patient outcomes.

Conclusion: Echography is a valuable tool in primary care, offering significant benefits in terms of diagnostic efficiency, cost reduction, and patient satisfaction. Its incorporaton into medical curricula and routine pratice could transform prmary care delivery, particularly in resource-limited settings. This study underscores the need for broader adoption of echography in general practice .

ID 952- POCUS Use in French General Practice: The ECHO-MG Study

Mariela SKENDI [(1)] , Camilla AAKJAER ANDERSEN [(2)], Marion ALARD [(1)], Ilona FERAUDET [(1)], Clara JUILLET [(1)], Julie FROIDEVAUX [(1)], Gladys IBANEZ [(1)], Martin BACH JENSEN [(2)], Roxane LIARD [(3)]

(1) Sorbonne Université, Paris, France
(2) Aalborg University, Aalborg, Danemark
(3) Cabinet Médical Ipso, Paris, France

Context: Point-of-care ultrasound (POCUS), referred to in France as échographie clinique ciblée (ECC), is defined as an ultrasound examination integrated into clinical evaluation to rapidly address focused diagnostic questions. Its rapid expansion contrasts with the limited national data describing its real-world use and with the absence of formal recommendations supporting its implementation in general practice.

Objectives: The primary objective was to describe POCUS use in terms of frequency, duration, organs explored, indications, and perceived image quality. Secondary objectives assessed changes in diagnostic hypotheses, patient orientation, and treatment.

Methods: A prospective, multicentre observational study was conducted among GPs performing POCUS in private practices, health centres, and during home visits. Data were collected between 2023 and 2024 during a one-month inclusion period. For each POCUS examination, GPs completed an online questionnaire before and after POCUS. All patients who underwent a POCUS examination were eligible for inclusion, except minors and patients who declined participation. Ethical approval was obtained.

Results: Thirty-seven GPs from 11 French regions participated. They owned fixed (62%), portable (32%), or ultraportable (41%) devices; curvilinear and superficial probes were most frequently used. Participants had a median POCUS experience of 5 years and had completed a median of 3 training programs. A total of 655 patients were included. GPs used POCUS a median of 1.6 times per day. Median examination duration was 7 minutes. The main anatomical areas explored were the abdomen (24%), urinary tract (24%), musculoskeletal system (22%), and gynecological–obstetrical area (19%). GPs to obtained relevant findings in 95% of examinations. The primary indication for POCUS was answering a focused clinical question (88%). Single diagnostic hypotheses increased from 33.4% to 77.5% after POCUS. Diagnostic hypotheses changed in 68.8% of cases, imaging referrals in 40.4%, and the overall care pathway in 85.3%.

Discussion: POCUS provided rapid, clinically meaningful information, improving diagnostic clarity and informing management decisions. Its short duration demonstrates strong feasibility in general practice.

Conclusion: POCUS substantially influences diagnostic pathways and management decisions in French general practice. These findings highlight its growing role in frontline care and reinforce the need for national guidelines and structured training pathways to support safe, effective, and widespread adoption.

ID 793- Use of Ultrasound by French General Practitioners in Suspected Deep Vein Thrombosis: A National Cross-Sectional Study

Matthieu CALAFIORE, Jérôme GONÇALVES DE FREITAS

Lille, Wattrelos, France

Context: Deep vein thrombosis (DVT) is a major public health issue due to its morbidity and mortality. Diagnosis typically relies on venous Doppler ultrasound performed by specialists, but long waiting times can delay management and prompt empirical anticoagulation. Point-of-care ultrasound by general practitioners (GPs) could streamline patient care by reducing diagnostic delays and avoiding unnecessary treatments.

Objectives: To evaluate the ability of French GPs equipped with ultrasound to confirm or exclude DVT in daily practice and to describe their diagnostic and management approaches.

Methods: A national prospective observational study was conducted among GPs using ultrasound in primary care. For each patient with suspected DVT, practitioners completed a questionnaire recording clinical probability, ultrasound results, anticoagulant prescriptions, and referrals. Statistical analysis was performed with a significance threshold of $p<0.05$.

Results: Sixty-one cases were included. Ultrasound confirmed DVT in 36.1%, excluded it in 60.7%, and was inconclusive in 3.3%. Venous incompressibility was present in all confirmed cases. In 56.4% of negative or uncertain cases, an alternative diagnosis was found, mostly musculoskeletal disorders. Anticoagulant prescriptions were strongly correlated with ultrasound findings ($p<0.01$). Additional investigations and specialist referrals remained limited.

Discussion: Ultrasound performed by GPs enabled rapid diagnostic clarification, reducing delays and the need for empirical anticoagulation. Its integration into routine practice could improve care pathways, though diagnostic accuracy should be compared with specialist Doppler ultrasound.

Conclusion: Ultrasound performed by GPs appears to be an efficient diagnostic tool for suspected DVT. It supports timely decision-making, optimises anticoagulant use, and helps identify alternative diagnoses. Further comparative studies with reference imaging are required to validate its diagnostic accuracy and support broader implementation in primary care.

ID 678- Accuracy of point-of-care gallbladder ultrasound performed by general practitioners: a cross-sectional study

David HALATA, Dusan ZHOR, Roman SKULEC

Czech Society Of General Practice, Prague, Tchèque, république

Context: Point-of-care ultrasonography (POCUS) is increasingly used in primary care, yet evidence on the diagnostic accuracy of gallbladder ultrasonography performed by general practitioners (GPs) remains limited. Gallbladder disease is a frequent cause of abdominal pain, and rapid bedside assessment may improve triage and reduce delays in management.

Objectives: To determine the diagnostic accuracy of gallbladder POCUS performed by trained GPs in detecting cholecystolithiasis, compared with expert abdominal ultrasound examination.

Methods: This cross-sectional diagnostic accuracy study included consecutive adult patients presenting to GP practices with symptoms suggestive of biliary disease. All participating GPs completed standardized POCUS training. POCUS evaluation included gallstone detection, gallbladder wall assessment and presence of sludge. Expert ultrasound served as the reference standard. Sensitivity, specificity, likelihood ratios, predictive values and accuracy for solitary, multiple and overall cholecystolithiasis were calculated.

Results: Forty-three patients were enrolled; in 42 cases (97.7%) the gallbladder was successfully visualised. Mean age was 53.3±15.4 years and 71.4% were women. Right upper quadrant pain was present in 78.7% and a positive Murphy sign in 11.9% of patients. POCUS identified solitary gallstones in 33.3%, multiple gallstones in 19.0% and sludge in 14.3% of patients. Mean examination time was 263±190 seconds, significantly shorter in fasting patients (195±135 s vs 315±212 s; p=0.042). Diagnostic performance for any cholecystolithiasis showed sensitivity 95.45% (95% CI 77.16–99.88), specificity 95.00% (75.13–99.87). For solitary gallstones, sensitivity was 78.57% and specificity 100%, for multiple gallstones sensitivity reached 100% and specificity 91.18%.

Discussion: POCUS of the gallbladder performed by trained GPs displayed high diagnostic accuracy, consistent with previously reported results from emergency medicine and hospital settings. Examination was rapid and feasible during routine consultations. The lower sensitivity for solitary stones may reflect small size or difficult anatomical windows, whereas multiple stones were more readily visualised. These real-world data suggest that GP-performed POCUS can accelerate diagnostic pathways and may help reduce delays for specialist imaging.

Conclusion: General practitioners, after structured training, can accurately identify cholecystolithiasis using POCUS. Integrating gallbladder ultrasound into routine primary care practice has the potential to improve diagnostic efficiency and patient management. Further multicentre studies with larger cohorts are warranted to confirm these findings.

ID 654- Multiparametric ultrasound screening and PSA density enhance early detection of high-risk prostate pathology in primary healthcare

Mihai IACOB [(1)] , Andrei Sorin IACOB [(2)], Simona DRAGAN [(3)], Nilima KUNDNANI [(3)]

(1) Euvekus-The European Ultrasound Working Group In Family Medicine / Departament Of Cardiology, University Of Medicine And Pharmacy "victor Babes" Timisoara, Vienna, Autriche
(2) Euvekus-The European Ultrasound Working Group In Family Medicine / Departament Of Cardiology, Vasile Goldis Western University Of Arad, Faculty Of Medicine, Vienna, Autriche
(3) University Of Medicine And Pharmacy "victor Babes" Timisoara, Timisoara, Roumanie

Context: Early detection of prostate cancer in primary care remains challenging because PSA and Free PSA lack sufficient specificity, often leading to unnecessary specialist referrals. Multiparametric ultrasound (mp-US)—including elastography, microflow imaging, Doppler vascularity, prostate volume assessment, and structured PIRADS interpretation—offers a more accessible alternative to multiparametric MRI. Strengthening diagnostic capability at the primary care level promotes equity, timely triage, and patient-centred decision-making aligned with the principles of general practice.

Objectives: To evaluate the diagnostic performance of mp-US parameters combined with PSA, Free PSA, and PSA density (PSAD) for identifying high-risk prostate lesions, and to assess agreement between family physicians and urologists in biopsy decision-making.

Methods: Among 400 eligible men screened in primary care, 167 patients with abnormal PSA, lower urinary tract symptoms, or MP-US findings were included. Age ranged 26–94 years (median 65). Risk stratification incorporated PIRADS score, elastography (hard stiffness), microflow assessment, Doppler vascularity, PSA, Free PSA, prostate volume, and PSAD. Analyses included descriptive statistics, ANOVA across PIRADS groups, correlation tests, multivariate logistic regression, ROC analysis, age-stratified risk, and Cohen's kappa for inter-rater reliability.

Results: Most patients were aged 55–79 years (66%). PSA and Free PSA differentiated risk groups: normal (PSA 3.2 ng/mL, Free PSA 28%), BPH/moderate risk (5.8 ng/mL, 16%), and high-risk (10.2 ng/mL, 10%). PSAD increased progressively across PIRADS categories (p<0.001). Hard stiffness appeared in 50% of PIRADS 3 and 100% of PIRADS 4–5 lesions. Strong correlations were observed between PSAD and PIRADS (r=0.62) and between elastography and microflow (r=0.48). Independent predictors of high-risk lesions included: PIRADS 4–5 (OR 12.5), PSAD (OR 8.2), elastography (OR 3.1), microflow (OR 2.7), and Doppler score (OR 1.6). ROC analysis showed excellent accuracy for the combined model (AUC 0.94; sensitivity 92%, specificity 87%). Agreement between GPs and urologists improved from κ=0.48 to κ=0.82 after integrating mp-US and PSAD.

Discussion: MP-US features significantly enhance diagnostic precision compared to PSA-based assessment alone. The combined model supports more consistent triage decisions and reduces unnecessary referrals.

Conclusion: Multiparametric ultrasound integrated with PSA density enables accurate identification of high-risk prostate pathology in primary care and substantially improves urologist agreement, offering an equitable and accessible approach to early detection.

ID 627- Artificial intelligence-assisted focused cardiac ultrasound in primary healthcare

Mihai IACOB [(1)] , Simona DRAGAN [(2)], Nilima KUNDNANI [(3)], Andrei Sorin IACOB [(4)]

(1) Euvekus-The European Ultrasound Working Group In Family Medicine / Departament Of Cardiology, University Of Medicine And Pharmacy "victor Babes" Timisoara, Vienna, Autriche
(2) Departament Of Cardiology, University Of Medicine And Pharmacy "victor Babes" Timisoara, Timisoara, Roumanie
(3) Euvekus / Departament Of Cardiology, University Of Medicine And Pharmacy "victor Babes" Timisoara, Timisoara, Roumanie
(4) Euvekus / " Vasile Goldiş" Western University Of Arad, Faculty Of General Medicine, Arad, Roumanie

Context: Focused cardiac ultrasound (FOCUS) enhances cardiac assessment in primary care but is operator-dependent. AI integration may improve accuracy, reproducibility, and early detection.

Objectives: We aimed to evaluate the diagnostic performance of AI-assisted FOCUS (AI-FOCUS) performed by trained family physicians against blinded cardiologist-performed echocardiography.

Methods: We conducted a prospective, observational cross-sectional study in primary care in Romania (N = 1780; age 40–75 years). Patients had high cardiovascular risk (SCORE2-OP ≥10%) or symptoms suggestive of cardiac pathology. Exclusion criteria included prior cardiovascular disease, morbid obesity, and inadequate acoustic windows. Family physicians performed conventional FOCUS and AI-FOCUS using a Sonoscape-P60 system with Wis+ AI. Target endpoints were LVEF <50%, screening-level valvular abnormalities, and pericardial effusion. The reference standard was blinded cardiologist echocardiography within 24 h. Diagnostic performance was assessed with accuracy, sensitivity, specificity, PPV, NPV, and Cohen's κ. Five-fold cross-validation confirmed reproducibility.

Results: AI-FOCUS achieved 94.3% accuracy (95% CI 93.2–95.4), 89.9% sensitivity, 96.5% specificity, PPV 92.6%, NPV 95.1%, with excellent agreement (κ = 0.88). Cardiac abnormalities were present in 32.9%: valvular disease (42%), LVEF <50% (28%), and pericardial effusion (12%). AI-assisted LVEF <50% (OR = 6.05, p < 0.0001) and valvular abnormalities (OR = 4.05, p < 0.0001) were independent predictors of cardiac pathology. Diagnostic accuracy was consistently high across age, sex, and cardiovascular risk strata. It reliably detected LVEF < 50%, valvular disease, and pericardial effusion, supporting early triage and referral in primary care.

Discussion: AI-FOCUS substantially reduces operator dependency and allows standardized cardiac assessment in primary care. Its high

reproducibility supports early detection, risk stratification, and timely referral while minimizing unnecessary specialist visits.

Conclusion: AI-assisted FOCUS is a scalable and reliable tool for primary care cardiovascular screening, enabling early diagnosis of systolic/dyastolic dysfunction, valvular disease, and pericardial effusion. Integration into routine practice and telemedicine optimizes patient outcomes and efficiency in resource-limited settings.

(6) University Of Szeged, Department Of Radiology, Szeged, Hongrie
(7) University Of Szeged, Department Of Surgery, Szeged, Hongrie

Context: Abdominal aortic aneurysm (AAA) is an uncommon, yet potentially fatal condition due to its high mortality rate in the event of rupture. To ensure timely detection, several countries have introduced organised, invitation-based national screening programmes. In Hungary, such institutionalised and targeted screening is not yet available.

Objectives: The aim of our multiregional validation pilot study was to assess the feasibility and justification of implementing AAA screening within Hungarian primary care.

Methods: Following a brief practical training, ten general practitioners (GPs) joined the pilot screening programme. Point-of-care ultrasound recordings obtained during screening were validated by radiologists. Screening was offered to men aged 65–75 years irrespective of smoking status, as well as to men and women over 50 years of age with a personal or family history of aneurysmal arterial disease.

Results: To date, 309 screening examinations have been performed across five counties in Hungary. During the validation process, only six image sequences (1.98%) were deemed non-assessable. Among the 303 patients with valid examinations (mean age 69.5±3.1 years; 97.7% male; 21.8% current smokers), infrarenal AAA was identified in eight individuals, yielding a period prevalence of 2.64%. Three patients have since undergone vascular surgery. The mean examination time recorded during screenings conducted by GPs was 6.7±4.0 minutes.

Discussion: Introducing AAA screening into Hungarian primary care appears to be an efficient strategy for early detection. GPs are well positioned to reach the target population, and the low rate of non-assessable examinations suggests that the diagnostic process is feasible following brief training. Nevertheless, the overall success of such a screening programme depends heavily on the quality of training, the availability of resources, sustainable financing structures, and the maintenance of diagnostic accuracy.

Conclusion: These preliminary findings demonstrate that abdominal aortic aneurysm screening integrated into Hungarian primary care is both feasible and potentially clinically valuable, supporting further evaluation of its long-term effectiveness, cost-efficiency, and nationwide implementability.

Unbreak my heart

ID 2152- When 'something smells wrong': the role of clinical intuition in diagnosing heart failure

Sara FUMIS [1], Riccardo LUCIS [2]

(1) Primary Care, Gradisca D'isonzo, Italie
(2) District Care Department, Department Of Medicine, Gorizia, Italie

Context: This report originates from a rural group practice in Friuli-Venezia-Giulia, Italy, facing significant workforce shortages and fragmented care, tending to high patient loads and challenging diagnostic continuity. We present a case where systemic constraints and cognitive biases delayed diagnosing severe heart failure in a 61-year-old woman.

Methods: A 61-year-old female smoker with hypertension and obesity presented with a six-week persistent non-productive cough and exertional dyspnea. Despite lacking fever or purulent sputum, she was diagnosed with respiratory infections by multiple physicians and prescribed three antibiotic courses (amoxicillin-clavulanate, azithromycin, levofloxacin) without improvement. Subsequently, a new GP noted bilateral basal crackles and jugular venous distension. Trusting a clinical intuition that "something smelled wrong" despite the patient's naive cardiac history, the GP ordered NT-proBNP test. The result was 1,161 pg/mL. She was hospitalized for acute decompensated heart failure. Echocardiography revealed a dilated left ventricle with an ejection fraction (LVEF) of 28%. Coronary angiography was normal. She was discharged on guideline-directed medical therapy.

Originality: This case highlights "cardiac cough" as an underappreciated primary symptom of heart failure in a fragile and rural setting, where speed of visit is more required than precision. Unlike typical reports, it focuses on the intersection of diagnostic error a

Lessons learned and future implication: Persistent cough in patients with cardiovascular risk factors warrants cardiac investigation when respiratory treatments fail. Clinical intuition remains a vital safeguard against algorithmic errors. Our practice encourages testing for NT-proBNP for unexp

Discussion: Diagnostic reasoning is vulnerable to anchoring bias, especially when systemic pressures reduce consultation time. This case demonstrates that biomarkers like NT-proBNP are essential tools to objectively validate clinical suspicion and prevent diagnostic delays.

Conclusion: A common symptom like cough can mask life-threatening pathology. In rural settings with workforce shortages, maintaining a high index of suspicion and trusting clinical intuition are crucial for patient safety.

ID 2067- External Validation of the American Heart Association PREVENT Cardiovascular Disease Risk Equations Based on the CHARLS Database

Ma LI, Shan ZHOU, Taihong LV

Department Of General Medicine, Beijing Tiantan Hospital, Capital Medical University, Beijing, Chine

Context: In 2025, the American College of Cardiology (ACC) and the American Heart Association (AHA), in partnership with eleven other academic societies, updated the guidelines for hypertension prevention, detection, and management. A major revision is the endorsement of the PREVENT risk model—which integrates cardiovascular, renal, and metabolic parameters—as a tool to support risk communication and therapeutic decision-making.

Objectives: To assess the predictive performance, calibration, and discrimination of the PREVENT model for cardiovascular disease (CVD) in a contemporary Chinese population.

Methods: We used data from the China Health and Retirement Longitudinal Study (CHARLS) from 2011 to 2020. Primary outcomes were incident CVD and non-cardiovascular mortality. Discrimination was evaluated using Harrell's C-statistic under competing risk analysis; calibration was assessed via the slope of predicted versus observed risk. The PREVENT model was compared with the Framingham risk score, and the incremental value of adding glycated hemoglobin (HbA1c) was examined.

Results: Among 6,942 adults free of baseline CVD (mean age 58.1 years; 54.4% female), 1,792 CVD

events occurred over a median 9-year follow-up. The PREVENT model showed modest discrimination for CVD events (C-statistic = 0.609, 95% CI 0.532–0.686; AUC under competing risk = 0.596, 95% CI 0.581–0.611) and systematic underestimation of risk (calibration slope = 1.67, 95% CI 1.06–2.37). Notably, it performed better for predicting non-CVD death (AUC = 0.760). Compared with the Framingham score, PREVENT offered slight improvements in discrimination (C-statistic 0.598 vs. 0.583), calibration (slope 0.82 vs. 0.36), and net reclassification (overall NRI = 0.035; men = 0.139). Adding HbA1c did not meaningfully enhance performance.

Discussion: PREVENT showed limited discrimination and systematic CVD risk underestimation, though modestly outperforming Framingham. Competing mortality and population risk differences may reduce transportability. Recalibration and local refitting are needed before clinical risk classification; HbA1c added little.

Conclusion: In this community-based Chinese cohort, the PREVENT model exhibited limited discriminative ability and a tendency to underestimate CVD risk. Although it outperformed the Framingham score, its accuracy remains insufficient for direct clinical use in China without prior recalibration and external validation using local population data.

Corresponding author: Shan Zhou, 972935355@qq.com

ID 2033- Electrocardiography in Out-of-Hours Chest Pain in the Netherlands: Use, Yield, and Clinical Impact

Indra MELESSEN, Michelle DE JONG, Jelle HIMMELREICH, Amy MANTEN, Eric MOLL VAN CHARANTE, Ralf HARSKAMP

1. amsterdam Umc, University Of Amsterdam, Academic Medical Center, Department Of General Practice, Meibergdreef 9, 1105 Az Amsterdam, The Netherlands, Amsterdam, Pays-Bas

Context: Identifying patients with chest pain at risk of acute coronary syndromes (ACS) or other major adverse cardiovascular events (MACE) remains challenging in urgent out-of-hours primary care (OOH-PC). To support clinical decision making, the HEART score is used in emergency departments. The acronym HEART refers to History, Age, ECG, Risk factors, and Troponin, with each component scored from 0-2 points, for a maximum of ten. This score includes an electrocardiogram (ECG), which is often unavailable and not recommended by Dutch general practitioner guidelines.

Objectives: This study evaluates determinants of ECG use and its added diagnostic value within the HEART score in OOH-PC.

Methods: We conducted a diagnostic accuracy study involving consecutive patients presenting with chest pain at two OOH-PC centers with ECG capabilities in the Netherlands, from March 2023 to August 2025. The primary endpoint was major adverse cardiac events (MACE), including ACS, at six weeks after the index consultation, adjudicated blindly by two independent researchers. We analyzed factors associated with ECG use and compared the added diagnostic value of the HEART score, which includes ECG points assigned for repolarization disorders (1 point) or significant ST deviation (2 points), versus the HART score, which excludes ECG.

Results: A total of 285 patients were included, 8.8% experienced MACE; 67 (23.5%) underwent ECG evaluation at the OOH-PC. ECG use was not associated with specific patient characteristics. Among patients with ECG, the c-statistics for the HEART and HART scores were 0.89 (95%CI 0.78-1.00) and 0.91 (95%CI 0.81-1.00), respectively. At a threshold of three points, the HEART score showed a sensitivity of 100% (95%CI 54.1%-100%), specificity of 24.6% (95% CI 14.5%-37.3%), negative predictive value (NPV) of 100%, and positive predictive value (PPV) of 11.5%. The three point cut-off of the HART score yielded a sensitivity of 100% (95%CI 54.1%-100%), specificity of 26.2% (95%CI 15.8%-39.1%), NPV of 100%, and PPV of 11.8%.

Conclusion: In Dutch out-of-hours primary care, ECG use in patients with acute chest pain was limited and not guided by patient characteristics. When incorporated into structured risk scores with high-sensitivity troponin, ECG appears to offer limited added value. Funding: Dutch Heart Foundation (03-003-2022-0029)

ID 1718- Sex differences in the diagnostic pathway of patients with chest discomfort in general practice

Anique DOBBE [(1)] , Beatrijs B.N. HOORWEG [(2)], Dorien L. ZWART [(1)], Geert Jan DINANT [(2)], Frans H. RUTTEN [(1)], Hester M. DEN RUIJTER [(1)], Robert T. A. WILLEMSEN [(2)]

(1) Umc Utrecht, Department Of General Practice & Nursing Sciences, Utrecht, Pays-Bas
(2) Department Of Family Medicine, Maastricht, Pays-Bas

Context: There is a lack of knowledge about sex differences in the diagnostic trajectory of patients presenting during office hours with chest discomfort to the general practitioner (GP).

Objectives: We aimed to compare the diagnostic care pathways initiated by the GP for women and men presenting with chest discomfort.

Methods: A sex-specific analysis was conducted within a prospective registry involving 118 GPs in XXX and XXX. All patient contacts were registered during a two-week period, detailing the diagnostic steps for individuals presenting with chest discomfort. A 30-day follow-up was used to collect the outcomes of diagnostic tests and final diagnoses.

Results: Preliminary results. Among 22,294 consultations, 1.26% (n=280) concerned chest discomfort (56.4% women; 43.6% men, p=0.030). Women were less often referred (33.5% vs. 48.4%, p=0.012) and underwent fewer diagnostic investigations (38.6% vs. 50.0%, p=0.057) compared to men. During 30-day follow-up, none of the women were diagnosed with an acute coronary syndrome (ACS) or other life-threatening events (LTE). In contrast, eight men (6.9%) had an LTE; 5 an acute myocardial infarction, 2 unstable angina pectoris, and one pulmonary embolism. There were three clear misdiagnoses in men; a pneumonia (n=1) and only suspicion of cardiac disease (n=2) had to be rectified later in the disease trajectory into an ACS. No such cases of misdiagnosis occurred in women.

Discussion: Women presenting with chest discomfort in primary care were less frequently referred, underwent less diagnostic testing, and had lower rates of ACS or other life-threatening diagnoses compared to men.

Conclusion: Our results are insufficient to determine whether gender differences exist in the adequacy of diagnostic assessment of patients presenting with chest discomfort to GPs during office hours. Future studies with larger patient populations are needed to clarify this potential difference.

Corresponding author: Anique Dobbe, aniquedobbe@hotmail.com

ID 1324- How Often Do QT-Prolonging Drugs Really Prolong QT? A Systematic Review

Dragos Paul HAGIU [(1)] , Lina HAMDI [(2)], Edouard OLLIER [(3)], Sébastien BRUEL [(1)], Paul FRAPPÉ [(1)]

(1) Département Médecine Générale,faculté De Médecine Jacques Lisfranc De Saint Etienne,université Jean-Monnet, Saint-Etienne, Saint-Etienne, France
(2) Département Médecine Générale,faculté De Médecine Jacques Lisfranc De Saint Etienne,université Jean-Monnet, Saint-Etienne - Saint-Etienne (France), Saint-Etienne, France
(3) University Hospital Of Saint-Etienne, Saint-Priest-En-Jarez, France., Saint-Priest-En-Jarez, France

Context: Drug-induced QT interval prolongation is a well-recognized risk factor for life-threatening arrhythmias such as torsades de pointes (TdP). Despite the widespread prescription of QT-prolonging drugs, especially in primary care, the incidence and prevalence of drug-induced long QT syndrome (diLQTS) remain poorly characterized, particularly in outpatient settings.

Objectives: The aim of this study was to evaluate the incidence and prevalence of diLQTSnin cases where screening was performed in adults taking QT-prolonging drugs.

Methods: A systematic review of studies reporting incidence or prevalence of drug-induced QT prolongation in patients undergoing ECG monitoring was conducted in PubMed database. Observational and interventional studies assessing QTc >500 ms or ΔQTc ≥60 ms were included. Study quality was evaluated using Newcastle-Ottawa Scale for

observational studies and RoB 2.0 tool for interventional studies.

Results: Out of 501 records, 42 studies met inclusion criteria: 5 were interventional and 37 were observational (15 prospective cohorts, 14 retrospective cohorts, 8 cross-sectional), totaling 14756 patients. Methadone was the most frequently studied drug (17 studies), with reported QTc >500 ms incidence ranging from 0% to 16.2%, and TdP incidence of up to 3.17%. Other frequently studied drugs included hydroxychloroquine (5 studies), azithromycin (4), and antipsychotics such as haloperidol and quetiapine. Incidence of QTc >500 ms varied considerably across settings and drug classes, influenced by heterogeneous QTc correction formulas. Only four studies reported TdP cases, all associated with methadone, droperidol, or tyrosine kinase inhibitors such as Cabozantinib and Dasatinib.

Discussion: Drug-induced QTc prolongation is not uncommon across a range of widely used medications, yet its monitoring and risk remain inconsistently assessed—particularly in outpatient settings. While torsades de pointes was rarely reported, QTc > 500 ms occurred with notable frequency. Significant heterogeneity in QTc definitions, study populations, and ECG methodologies limits cross-study comparability, underscoring the need for greater standardization

Conclusion: Although TdP was rare, several studies reported that once diQTLS was identified, clinicians responded with therapeutic modifications—such as stopping or substituting the suspected medication. For clinicians—particularly in primary care—targeted QTc monitoring and individualized risk stratification, potentially supported by portable ECG technologies, may help improve patient safety.

Corresponding author: Dragos Paul Hagiu, dragos.paul.hagiu@univ-st-etienne.fr

ID 319- Severity of chest pain seems not to be a valuable diagnostic tool for primary care telephone triage in patients suspected of an acute coronary syndrome

Sander VAN DOORN, Mathe DELISSEN, Esther DE GROOT, Dorien ZWART, Frans RUTTEN

Julius Center For Health Sciences And Primary Care, University Medical Center Utrecht, Utrecht University, Utrecht, Pays-Bas

Context: Despite its complexity as a symptom, severity of pain score plays a prominent in clinical practice. Pain score has long been used at out-of-hours primary care serives (OHS-PC) for triaging patients with chest discomfort in the Netherlands but its value was questioned.

Objectives: To examine (i) how patients with chest discomfort report pain scores during telephone triage, (ii) how triagists record these scores, and (iii) the risk of acute coronary syndrome (ACS) for these reported and recorded scores.

Methods: In a cross-sectional study we used data from adult patients calling with chest discomfort to 7 OHS-PC in the Netherlands. Backed up recordings of telephone triage conversations we re-listened. Pain scores mentioned by patients were compared to pain scores recorded by triagists using descriptive statistics. Final diagnoses were retrieved from health records.

Results: We included 2,322 triage conversations with mean age 56.5 (SD 19.4) years, 54.0% were women. In 1,510 (65.0%) of all 2,322 triage conversations, the patient had rated pain score on a scale of 0 to 10. In 2,062 (88.8%) of all conversations, a pain score was registered by the triagist in 1 of 3 categories (no/light pain, moderate pain, severe pain). In the 1,250 triage conversations where the pain score was both registered and reported the scores were identical in 80.9% of the cases. A lower pain score was registered by the triagist than reported by the patient in 160 (12.8%) conversations, and a higher pain score in 48 patients (3.8%). Risk of ACS was highest for highest pain scores registered by the triagist, irrespective of the score reported by the patient.

Discussion: Our study shows that pain scores often are not explicitly reported by patients but estimated instead or, even when collected, up- or downscaled by triagists to tinker the outcome of triage. This reflects both the inherently subjective nature of pain and communicating about pain, and the

limitations of applying a single-point score with a strict cutoff.

Conclusion: Patient-reported pain scores offer little reliable information and have no practical value for triaging patients with chest discomfort.

Undergraduate training

ID 1798- Why are our medical graduates choosing General Practice? What are we doing right?

Jane SMITH

Bond University, Gold Coast, Australie

Context: Around the world there is a decline in graduates choosing a career in general practice(GP). This is despite data showing strengthening GP and GP continuity of care leads to improved health, lower mortality, and reduced healthcare-system costs. Many countries rely on importing GPs from other countries, who provide great value. Ideally capturing home grown doctors We have data showing our medical program has the highest percentage ot graduates choosing to work in metropolitan general practice in the country.

Objectives: This presentation will discuss the national statistics and identify the elements of medical education associated with inspiring graduates to choose the specialty of general practice.

Methods: The national analysis on GP trainees is based on data of graduates from all medical schools in our country. This data will be shared along with specific characteristics of university medical school education programs that appear to cause a higher percentage of graduates to choose general practice as their training pathway. Insights about rural GP training pathways will be included in this data.

Results: This national data of all medical graduates in our country was generated for the first time in 2025. The results were not intuitive nor anticipated, as they were different to expected. The percentage of medical graduates choosing general practice vary from 52% to 16%. Our medical school shows the highest percentage of graduates choocing to train in metropolitan GP.

Discussion: Many previous papers have looked at characteristics that are associated with working in rural GP, or career intentions of new graduates; this reveals genuine GP training intent. This is why it is important to reach better understanding of what ingredients in medical students' education make them more likely to choose GP. Comparing GP medical education and clinical placements between the universities with greater success in producing GPs will help identify how to improve graduate career choice in GP.

Conclusion: Graduates have a higher interest in GP than thought and the medical schools producing GPs can be a surprise. The national data combined with information about university GP training (in clinic or classroom) highlights the essential design ingredients of medical training to enhance graduate choice of GP.

ID 1702- Forum Theatre and Simulated Consultations to Develop Relational Competencies in Undergraduate Medical Education

Solène BLANCHIN

Université Grenoble Alpes, Grenoble, France

Context: Relational and emotional competencies are core skills for general practitioners and are associated with patient satisfaction, adherence to care, and physician well-being. Although included in competency-based medical curricula, these skills remain unevenly taught and insufficiently practiced during the clinical years of medical training, prior to specialty selection. Experiential and arts-based pedagogies may address this gap by fostering empathy, reflexivity, and communication skills.

Objectives: To describe and evaluate an interdisciplinary educational programme combining forum theatre and simulated consultations to support the development of relational competencies in medical students.

Methods: A retrospective mixed-methods study was conducted over two academic years. All fourth-year medical students participated in mandatory forum theatre workshops, and all sixth-year students took part in mandatory simulated consultations. The programme was delivered through collaboration between medical educators and performing arts professionals. Data were collected using anonymous self-administered questionnaires completed immediately after each session. Quantitative data were analysed descriptively using five-point Likert scales assessing perceived quality, emotional comfort, and usefulness for developing relational competencies. Qualitative data from open-ended responses were analysed using inductive thematic analysis.

Results: A total of 568 students responded (mean response rate 63%). Forum theatre sessions received a mean global satisfaction score of 4.6/5 and perceived usefulness of 4.1/5, while simulated consultations scored 4.7/5 and 4.4/5 respectively. More than 95% of participants recommended continuation of the programme. Qualitative analysis identified three main themes: recognition of relational competencies as essential and insufficiently addressed elsewhere in the curriculum; the formative role of emotions when experienced within a safe and non-judgemental learning environment; and enhanced professional reflexivity, including increased awareness of empathy erosion and depersonalisation during training. Students suggested organisational improvements, including smaller group sizes and extended debriefing time.

Discussion: This interdisciplinary and experiential programme was perceived as complementary to traditional teaching and clinical placements, with emotional engagement acting as a key driver of reflective learning.

Conclusion: Forum theatre and simulated consultations appear to be effective and scalable approaches to developing relational competencies in undergraduate medical education. Their sustained integration into curricula may contribute to more patient-centred and reflective future general practice.

ID 1280- Trainer training initiatives in primary healthcare: part of a national, EU supported project in the Czech Republic

Ludmila BEZDICKOVA [1] , Jachym BEDNAR [1], David MACHARACEK [1], Barbora MEDOVA [1], David HALATA [2], Katerina JAVORSKA [2], Lucie SEFRHANSOVA [1]

(1) Euract, Institute For Postgraduate Medica Education, Prague, Society Of General Practice Czech Republic, Prague, Tchèque, république
(2) Euract, Euripa, Institute For Postgraduate Medica Education, Prague, Society Of General Practice Czech Republic, Prague, Tchèque, république

Context: Each year, 150–200 physicians complete GP board certification in the Czech Republic, which is sufficient for generational replacement. The main challenge, however, is their uneven distribution, threatening continuity of primary care in regions most affected by GP shortages. The aim of the project is to improve GP recruitment through education.

Methods: A three-year nationwide project Support for education in primary care for general practitioners, paediatric general practitioners, and support for regional accessibility of healthcare (Project registration number: CZ.03.02.02/00/24_060/0005126), co-financed by the European Social Fund through the Employment Plus Operational Programme and the state budget of the Czech Republic, was launched by the Institute for Postgraduate Medical Education (IPVZ) in 2025. The project includes several key activities focusing on 1. Regional GP education, 2. Competency-based education, methodology of specialty training and improvement of the assessment of education, providing and cascading education for trainers in GP, 3. Education for nurses in general practice (pilot). The presented work focuses on key activity 2.

Originality: To support competency-based education for trainees and trainers, we innovated a skills book for specialty training. We developed a shortened two-day Leonardo course for GP trainers

(modelled after EURACT). The project supports the production of the origin

Lessons learned and future implication: The project will produce national guidebooks—How to be a good GP trainer and How to organize Leonardo courses—to support regional cascading. A supervision process will be established to improve the quality of GP training assessment. A survey evaluating sp

Discussion: Improving GP recruitment requires a targeted approach and strong multidisciplinary cooperation, with education as a central component. Our efforts aim to stimulate interest in rural medicine, strengthen educational quality through trainer development, and build data to guide further strategic planning.

Conclusion: Transforming GP education requires a nationwide, well-resourced effort. This EU-supported project led by IPVZ enables substantial methodological progress and provides a framework for future national and regional initiatives in the field.

ID 874- A new competency-based portfolio for the sixth-year Family Medicine internship based on the WONCA definition

Paulo SANTOS [(1)] , Joana MONTEIRO [(2)], Mariana Paupério BENTO [(2)]

(1) Medcids; Rise-Health@rise; Faculty Of Medicine; University Of Porto, Porto, Portugal
(2) Medcids; Faculty Of Medicine; University Of Porto, Porto, Portugal

Context: Competency-Based Medical Education (CBME) emphasizes observable performance in authentic clinical settings. In Portugal, undergraduate Family Medicine training remains heterogeneous and predominantly knowledge-based, with limited alignment to internationally recognized competencies. This gap calls for structured tools that support competency development and assessment during clinical internships.

Objectives: To develop and validate a competency-based portfolio aligned with the WONCA definition of Family Medicine competencies for use in the sixth-year internship.

Methods: A mixed-methods validation study was conducted in three phases. First, Family Medicine experts identified tasks illustrating the 18 competencies through an open-ended questionnaire. Responses were synthesized into 22 preliminary learning outcomes. Second, content validity was assessed by a large panel of Family Medicine physicians using a 5-point Likert scale; consensus was defined as an Item-Level Content Validity Index (I-CVI) ≥0.80. Third, tasks failing to reach consensus were reformulated and re-evaluated in a subsequent validation round.

Results: In the first validation round (n=117), 19 of 22 tasks achieved I-CVI ≥0.80. Two tasks were reformulated and validated in a third round (n=113), reaching consensus (I-CVI=82.3% and 92.9%). The final portfolio comprises 22 competency-based tasks covering clinical, communicational, organizational, and community-oriented dimensions of Family Medicine practice.

Discussion: This portfolio operationalizes CBME principles by translating abstract competencies into observable behaviors, promoting authentic assessment and reflective learning. It introduces new perspectives for undergraduate education, including integration of community and system-level competencies, fostering feedback culture, and creating a foundation for Entrustable Professional Activities.

Conclusion: The validated portfolio offers a structured, feasible tool for implementing CBME in Family Medicine internships. Future research should explore its impact on student engagement, readiness for practice, and career choices, as well as its potential to strengthen continuity between undergraduate and postgraduate training.

ID 766- Stigma against people living with human immunodeficiency virus: a quasi-experimental evaluation of active stigma

reduction workshop among medical students

Imen MLOUKI, Emna BAOUEB, Emna HARIZ, Aya AJMI BLOUT, Haythem AYACHI, Sana EL MHAMDI

Preventive And Community Medicine Department, Faculty Of Medicine Of Monastir, University Hospital Of Mahdia, Mahdia, Tunisie

Context: Stigma against People Living with Human Immunodeficiency Virus (PLHIV) particularly from healthcare providers continues to be a significant barrier discouraging individuals from seeking necessary care. HIV stigma is still underexplored particularly among healthcare workers with limited focus on medical students.

Objectives: This study aimed to assess the impact of active stigma reduction workshops on stigma towards PLHIV among a sample of medical student in XXX and to identify its related factors.

Methods: We performed a quasi-experimental study among all fifth-year students during the academic years 2024 and 2025 in the Faculty of Medicine of XX (XX). We evaluated HIV stigma before and after each workshop via self-administrated and anonymous questionnaire. We used the validated versions of the brief HIV knowledge questionnaire and the Health Care Provider HIV/AIDS Stigma Scale.

Results: A total of 216 medical students answered completely to the questionnaire. Overall, most participants demonstrated a good level of HIV-related knowledge (88.4%). Good HIV knowledge, higher parental education and involvement in community or associative activities were significantly associated with lower stigma levels. Interestingly, poor parental educational level and being stigmatized were independently associated with higher prejudice scores in multivariate analysis. The student centered learning (SCL) approach was revealed to be effective in significantly improving HIV-related knowledge and reducing stigma among medical students.

Discussion: Beyond its implication in general medial subjects, SCL method has also been explored in our primary focus, enhancing HIV-related knowledge and reducing stigma against PLHIV. For instance, studies in Sudan and the United States highlights the effectiveness of SCL and peer-based approaches in promoting HIV awareness and reducing HIV stigma among students. In addition, in China, a web-based game was developed to reduce HIV-related stigma. The game used participatory gamification and storytelling to immerse university students in the lives of PLHIV. This approach enhanced empathy-building, active learning through problem solving and reflection.

Conclusion: Our findings emphasize the value of integrating active learning methods into medical curriculum to prepare future healthcare providers to deliver stigma-free care in order to promote ethical and inclusive behavior toward PLHIV.

ID 275- On-Call GP: An Experiential, Role-Play Based Game to Strengthen Patient-Centred Consultation Skills in Primary Care and Inspire GP Careers

Neepa THACKER, Holly YOUNG, Zalli ARGITA, Arti MAINI

Imperial College London, London, Royaume-Uni

Context: It is vital to inspire more medical students to consider general practice careers, amid a GP recruitment crisis. To counter negative perceptions of the profession due to the 'hidden curriculum', undergraduate teaching should engage students in a more balanced way, showcasing positive aspects of general practice. To address this, we developed a novel game-based session, 'On-Call GP: The Consultation Game', for Year 5 medical students. The session design was informed by Kolb's experiential learning theory and incorporates an adapted version of an educational board game, simulating a GP clinic. Students work in small groups to test clinical knowledge, role-play consultations and manage on-call challenges. A GP tutor-facilitated debrief aims to consolidate learning.

Objectives: We aimed to evaluate the impact of our game-based session on students' engagement in learning, sense of connectedness with peers, development of clinical knowledge and consultation skills and perception of general practice.

Methods: All students participating in the 'On-Call GP: The Consultation Game' session were invited to complete a post-session anonymised Qualtrics survey. Likert scales evaluated students' perceptions of the session's engagement and usefulness, its impact on developing clinical skills, and their sense of connectedness with peers. Free-text questions further explored students' experiences of the session and its impact on their perception of general practice.

Results: Six sessions have taken place between July and November 2025. Sessions were completed by 125 students. The survey response rate was 74%. The evaluation found that the majority of students agreed the session was engaging, improved their clinical skills and enabled them to feel connected to peers. Free-text responses highlighted the value of peer-learning, role-play and debrief in developing consultation skills and consolidating clinical knowledge. Students commented on the 'fun, engaging' nature of the session and on developing a more positive impression of general practice.

Discussion: Game-based experiential educational sessions may add value through increasing engagement with learning and providing students with insights into the varied and complex nature of general practice.

Conclusion: An experiential, game-based approach can enable students to strengthen connections with peers, develop clinical skills and develop a positive perception of general practice.

ID 378- Stakeholders' Perspectives on a Novel Competency-Based Assessment for General Practice: A Qualitative Study

Wei Ping YEW, Md Nassif HOSSAIN, Arunaz KUMAR, Dragan ILIC, Peter BARTON, Jennifer NEIL

Monash University, Melbourne, Australie

Context: Competency-based approaches are increasingly adopted in medical education to prepare medical students for clinical practice. The COVID-19 pandemic highlighted challenges in clinical assessments such as the Objective Structured Clinical Examination (OSCE) and drove innovation in assessment designs. In the post pandemic era, new assessment models require critical evaluation.

Objectives: This study explored stakeholders' perspectives on a novel General Practice (GP) competency-based assessment, the Clinical Assessment for Progression Examination (Clinical APEx), evaluating its acceptability, authenticity, feasibility, and educational impact.

Methods: A qualitative study using an interpretivist approach was conducted. Thirty-one participants including medical students, examiners, simulated patients, and administrators engaged in semi-structured interviews. Data were transcribed, coded and thematically analysed.

Results: Five themes were identified: Student Wellbeing, Authenticity of the Assessment, Results and Outcomes, Feedback and Assessment for Learning, Organisation of the Assessment. Clear assessment expectations, less rigid format and competency grading framework contributed to improved student wellbeing and assessment acceptability. The GP Clinical APEx offered authentic doctor-patient interactions, though its exclusive focus on examination skills limited reflection of clinical practice. In terms of results, delivering immediate, unfavourable outcomes proved challenging. Tailored feedback supported skills development, strengthening its educational impact. Organisational demands were reduced, supporting feasibility.

Discussion: The GP Clinical APEx was viewed as less stressful and more acceptable than the traditional OSCE, offering clarity, flexibility, and competency-based grading. Timely and carefully constructed feedback enhanced student development. In contrast, the often delayed, non-interactive or absent feedback in the OSCE limited learning. Difficulty in delivering immediate unfavourable results may contribute to the phenomenon of "failure to fail". The GP Clinical APEx streamlined logistics contrasted with the OSCE's high resource demands.

Conclusion: Stakeholders recognised the GP Clinical APEx as an acceptable and feasible competency-based assessment. By embedding

feedback and emphasising assessment for learning, it supported student development and strengthened educational impact. Future iterations should enhance authenticity by integrating clinical reasoning, and further research is needed to establish validity and reliability.

Vaccines

ID 1730- Parental confidence in childhood vaccine safety and effectiveness in Albania.

Ledia QATIPI [1] , Albana FICO [1], Arlinda RAMAJ [2], Michael HARRIS [3]

(1) Biomedical And Experimental Department, Faculty Of Medicine, University Of Medicine, Tirana, Tirana, Albanie
(2) Local Health Care Unit Tirana, Department Of Epidemiology And Environmental Health, Tirana, Albanie
(3) Department For Health, University Of Bath, Bath, Uk, Tirana, Albanie

Context: Vaccine hesitancy (VH) is an increasing global concern, contributing to vaccine preventable disease outbreaks. According to the Albania Demographic and Health Survey, childhood vaccination rates in Albania have dropped from 94% in 2008-2009 to 75% in 2017-2018. In 2023, WHO reported 83% coverage for the first dose of the MMR vaccine in Albania.

Objectives: The study aimed to (1) assess Albanian parents' confidence in the safety and effectiveness of vaccines, (2) identify which parental beliefs have the greatest influence on the decisions of hesitant and refusing parents, and (3) determine the prevalence and sources of negative vaccine information and their impact on parental decision-making.

Methods: This cross-sectional study surveyed 4,082 randomly selected Albanian parents and legal caregivers of children aged 0–18 years. Using a validated and ethically approved anonymous questionnaire, data were collected from participants at randomly selected primary health care centres across Albania. The questionnaire consisted of sociodemographic data and questions about participants' behaviours, attitudes, and beliefs regarding vaccine safety and efficacy. Data was analysed by using percentages, Pearson's Chi-squared test, and Fisher's exact test.

Results: 27.3 % and 17.6% of all respondents self-reported VH and vaccine refusal, respectively. A large number of hesitant and refusing parents reported that "They are concerned about serious adverse effects of vaccines (73%), "It's better for children to get fewer vaccines at the same time" (65%), and "It's better for children to develop immunity by getting sick than by getting vaccinated "(40%). Hesitant and refusing parents are more likely to report having received or heard negative information from their friends and family members (61%), internet (58%) and social media (49 %) P value < 0.001.

Discussion: The majority of hesitant and refusing parents expressed concerns about serious vaccine side effects, prefer fewer vaccines at one time, and believe natural infection is preferable to vaccination, often influenced by negative information from family and friends. These findings highlight the need for targeted strategies to specific parental beliefs.

Conclusion: Addressing VH in Albania requires multifaceted, targeted strategies tailored to specific parental beliefs. Engagement of trusted healthcare and community professionals will increase parental confidence and improve childhood vaccine uptake.

ID 1612- Evaluating pregnant women's satisfaction with prenatal care and their attitudes toward childhood vaccination

Esra SAATCI

Cukurova University Faculty Of Medicine Department Of Family Medicine, Adana, Türkiye

Context: Antenatal care is essential for a healthy pregnancy. Moreover, mothers' attitudes towards childhood vaccines are among the most important factors determining infant immunization rates.

Objectives: This study was conducted to assess the pregnant women's satisfaction with prenatal care and their attitudes toward childhood vaccines.

Methods: This cross-sectional study included 146 pregnant women who applied to the Çukurova University Training Family Health Centre between 1 May 2024 and 31 July 2024. Sociodemographic Data Questionnaire, Prenatal Care Satisfaction Scale (PCSS) and Vaccination Attitudes Scale (VAS) were administered.

Results: The mean age of pregnant women was 29,4±4,1 year (median: 29). Overall, 98,6% of the participants were married, 68,5% were university graduates, 45,2% were employed, and 50,7% had more than one pregnancy. The mean score of PCSS was 82,9±15,4. The mean total score, and the art of care, technical quality, accessibility, and physical environment subscale scores were significantly lower among participants with two or more pregnancies compared to in their first pregnancy (p=0,014; p=0,041; p=0,032; p=0,004; p=0,009, respectively). The mean VAS score was 17,4±3,8. The efficacy and safety subscale score of pregnant women was significantly associated with employment status (p=0,044), educational level (p=0,004), and income (p=0,003). No significant relationship was found between prenatal care satisfaction and pregnant women's attitudes toward childhood vaccination.

Discussion: As pregnant women's educational levels increase, their expectations of health care professionals also rise. Full-time employed and highly educated pregnant women tend to have more positive attitudes towards vaccination.

Conclusion: Pregnancy represents an important opportunity for family physicians to influence parental decisions regarding childhood vaccination

ID 339- Vaccination and Teambuilding in an Interdisciplinary Setting: How to Make It Fun?

Clara BLANCHARD [(1)] , Andrea POPPELIER [(2)], Damien ALBERT [(2)], Alexandre PEYRIDIEUX [(2)]

(1) Mspu Coeur De Saintonge, Pont L Abbe D Arnoult, France
(2) Mspu Coeur De Saintonge, Saint-Porchaire, France

Context: Adult vaccination coverage in France remains low: only about 50% of adults receive the DTP booster at age 65, and fewer than 5% of patients with diabetes have completed pneumococcal vaccination. In August 2023, French regulations expanded vaccination prescription rights to nurses and pharmacists to improve coverage. The Coeur de Saintonge Health Care Center (CSHCC) is a rural multidisciplinary facility with 42 health-care professionals (general practitioners, nurses, pharmacists, midwives, etc.). In 2024, a vaccination working group of the CSHCC began to develop innovative, collaborative strategies to increase vaccination coverage across its territory, while also improving team cohesion.

Methods: In May, an interdisciplinary meeting is organised to present annual updates to vaccination guidelines to all CSHCC professionals. Every year, the working group selects a specific vaccination target—based on both national recommendations and local needs—and sets a collective objective to be achieved over a four-month summer period. A visual communication campaign supports both the population and professionals during this period. Monthly updates are provided to health-care professionals regarding individual and collective progress, and final performance feedback is shared at the end of the surveillance period.

Originality: This approach combines a population-level vaccination strategy with an internal teambuilding component. An internal taskforce defines the annual vaccination protocol, integrating guideline updates with local epidemiological priorities. The initiative prom

Lessons learned and future implication: In the first year, the protocol adopted a competitive structure between professionals, which limited its impact on teambuilding. In response, the second year's protocol shifted toward a shared goal, creating a more supportive environment and strengthening

Discussion: Over the past two years, adult DTP booster coverage and pneumococcal vaccination

among patients with diabetes have significantly improved within the CSHCC population. Notably, these improvements persisted beyond the targeted surveillance periods.

Conclusion: The combination of updated guidelines, targeted objectives, structured feedback, and playful teamwork appears to be an effective strategy for increasing vaccination coverage while reinforcing interprofessional collaboration in primary care settings.

ID 1252- Improving immunization coverage through retrospective audit of routine vaccination practices in primary care

Irine KAROSANIDZE, Tamar GABUNIA, Lali GELASHVILI, Nana KIKABIDZE, Ushangi KILADZE, Nino KIRTADZE, Eka GIGASHVILI

National Family Medicine Training Center, Tbilisi, Géorgie

Context: Following large-scale national training of over 3,000 primary health-care (PHC) workers on routine immunization practices, a retrospective audit was conducted to evaluate whether these capacity-building efforts translated into measurable improvements in routine vaccination performance. The review took place in the context of newly introduced age-adjusted capitation and results-based financing mechanisms, which increased the importance of accurate immunization registration, timely service delivery, and achievement of national target indicators.

Methods: A comprehensive audit of immunization coverage among 1445, 0–6-year-old beneficiaries was conducted using multiple data sources, including the national health information system, immunization modules, and locally used planning/monitoring tools. The assessed period covered July 2024 to June 2025. Coverage was reviewed for key vaccines (Hexa-3, MMR-1, MMR-2, Tetra R1, Tetra R2) by age group and PHC team. Strengths included the availability of detailed age-disaggregated data and team-level comparisons. Limitations included inconsistent denominator definitions, unrecorded parental refusals, electronic system constraints, and incomplete accounting for inactive or migrated children.

Originality: This experience is one of the first facility-level audits aligned with the new PHC reform indicators and combines administrative data with operational reflections from PHC teams. Unlike earlier post-training supervision, this audit quantified delays, asse

Lessons learned and future implication: Findings highlighted strong team engagement and functioning reminder systems, but also systemic delays: Hexa-3 timely coverage remained low among 0–11-month-olds (62.9%), MMR-1 coverage at 12–23 months reached only 63.5%, and MMR-2 coverage at 5–6 years r

Discussion: The findings demonstrate that while overall coverage was acceptable for some vaccines, timeliness and data accuracy remained major challenges. Integrating updated electronic systems and harmonizing local measurement practices with national standards are essential for future improvements.

Conclusion: This audit illustrates how systematic, multi-source data review can reveal quality gaps in routine immunization even among well-trained PHC teams and provides actionable insights for improving timely vaccination and meeting national results-based financing targets.

ID 893- The Effect of Structured Counseling Given to Parents Influenced by Social Media on Vaccine Hesitancy: An Intervention Study

Birkan BAYRAK, Gizem LIMNILI, Nilgun OZCAKAR

Department Of Family Medicine, Faculty Of Medicine, Dokuz Eylul University, izmir, turkey, Izmir, Türkiye

Context: Social media is an important source through which misinformation and disinformation that cause parents to hesitate about vaccines spreads rapidly. Family physicians, thanks to the continuous and trust-based relationship they

establish with parents, are in a unique position to reduce this information pollution and provide evidence-based guidance.

Objectives: To evaluate the effect of brief and structured counseling delivered by family physicians on vaccine hesitancy and vaccination decisions among parents who are influenced by social media.

Methods: This randomized controlled study will be conducted in the family medicine clinics of the training family health centers (EASM) of İzmir Dokuz Eylul University. Parents of children aged 0–5 years who report social media as their main source of vaccine information and who have high vaccine hesitancy (according to the PACV score) will be included in the study. After the baseline assessment (PACV score, sociodemographic data, and the child's vaccination status), participants will be randomly assigned to the intervention or usual-care group. In the intervention group, family physicians will conduct an approximately 10–15-minute structured face-to-face counseling session focusing on common myths, vaccine safety, and the risks of vaccine-preventable diseases, and will provide an evidence-based information leaflet. The control group will receive routine counseling. PACV scores and on-time vaccination status will be reassessed 1–3 months later.

Results: The study is in the planning phase. In the intervention group, compared with usual care, a greater decrease in PACV scores and a higher rate of on-time vaccination are targeted.

Discussion: The study is in the planning phase. In the intervention group, compared with usual care, a greater decrease in PACV scores and a higher rate of on-time vaccination are targeted.

Conclusion: If found effective, this individualized, brief, and structured counseling, tailored to parents influenced by social media, may be recommended to be integrated into routine family medicine practice as a practical communication strategy against vaccine hesitancy.

ID 703- Regional trends in childhood vaccination coverage in Brazil before and after the COVID-19 pandemic: implications for Primary Health Care

Cezanne BARBOSA, Marcio MELO, Naila OLIVEIRA

São Leopoldo Mandic School Of Medicine, Araras, Araras, Brésil

Context: Childhood immunization coverage has declined globally since the COVID-19 pandemic, raising concerns about the capacity of Primary Health Care (PHC) to sustain routine preventive services. In Brazil, PHC teams coordinate the childhood vaccination pathway, including neonatal follow-up, routine infant care and outreach activities. However, regional disparities and post-pandemic behavioral changes may affect the ability of PHC to maintain vaccination coverage.

Objectives: To assess regional trends in childhood vaccination coverage in Brazil from 2016 to 2022, comparing pre-pandemic and post-pandemic periods and identifying vaccines most affected within the PHC child care continuum.

Methods: This ecological time-series study used secondary data from the National Immunization Program. Five childhood vaccines representing key stages of PHC-based child care were analyzed: BCG, Hepatitis B (30 days), Pentavalent, Poliomyelitis (1 year) and Yellow Fever. Annual coverage (%) was compiled for the five Brazilian macro-regions from 2016 to 2022. Temporal trends were estimated using Prais–Winsten regression, generating Annual Percent Change (APC) and p-values. The time frame was structured to evaluate changes between the pre-pandemic period (2016–2019) and the post-pandemic period (2020–2022).

Results: BCG coverage showed a borderline decline in the Southeast and a significant decline in the Centre-West. Pentavalent vaccination declined significantly in the North, Southeast and Centre-West. Poliomyelitis coverage decreased significantly in the Southeast and Centre-West. Yellow fever vaccination declined significantly in endemic regions, while increasing borderline in the Northeast. Hepatitis B (30 days) remained stable across all regions.

Discussion: The findings indicate progressive erosion of childhood immunization within PHC, especially for vaccines that depend on continuous engagement with PHC teams. Beyond operational disruptions, the post-pandemic period has been marked by growing vaccine hesitancy, misinformation and the circulation of antivaccine narratives, which have disproportionately affected parental confidence in routine childhood immunization. These behavioral factors may have amplified pre-existing regional inequalities and hindered the effectiveness of PHC-based strategies such as active outreach, counseling and community engagement.

Conclusion: Childhood vaccination coverage in Brazil declined unevenly, with significant reductions in key PHC-dependent vaccines. Strengthening PHC capacity, rebuilding vaccine confidence and implementing evidence-based communication strategies are essential to reverse post-pandemic declines and address emerging vaccine hesitancy.

Violences

ID 2091- The House of Women: a resource for all women, healthcare professionals and society

Catherine PLOTTON, Alicia PEREIRA, Xavier GOCKO

Department Of General Practice, Faculty Of Medicine Jacques Lisfranc, University Of Lyon, Saint-Etienne, France; Inserm Cic-Ec 1408., Saint-Etienne, France

Context: Between 2000 and 2018, nearly one in three women worldwide had experienced physical or sexual violence. This violence had an impact on their health (physical, mental, sexual and reproductive). With regard to primary healthcare, numerous resources have been developed to help caregivers identify and care for women who are victims of domestic violence. In France, in 2016, the first House of Women was created to offer a single, multidisciplinary and local care pathway and treatment facility. In 2021, a House of Women project was launched in Annonay (a rural commune of 16 359 inhabitants located in the Ardèche department).

Objectives: To explore the expectations of healthcare professionals in Annonay regarding the creation of House of Women.

Methods: A qualitative study using a grounded theory approach was conducted with healthcare professionals through individual interviews in Annonay in 2024 until sufficient data. Theoretical sampling was based on type of profession, mode of practice (primary care or hospital), age and gender. The COREQ 32 criteria were followed. This work was approved by a Ethics Committee.

Results: Fifteen healthcare professionals participated. They described the House of Women as a referral center for all women, offering a warm welcome, a listening ear and information. Professionals disagreed as to whether it should be located in the city center or more hidden, in the hospital or not. They agreed it had to be accessible geographically and temporally. Its team had to be benevolent and reassuring. It was also imagined as a centralized and multidisciplinary team for an optimized pathway in complete safety. It was seen as a necessary reflex for society, with preventive and educational actions at a population level.

Discussion: Whether or not the Women's Centre is located within the hospital, can it not nevertheless provide a reassuring and welcoming environment? A qualitative study conducted in the United Kingdom among hospitalised patients on their perception of the hospital revealed that they perceived it as a favourable environment.

Conclusion: This work could be useful for projects to set up Houses of Women. Next step is an evaluation of the house of women by users..

(2) Servicio De Urgencias. Hospital Del Rio Hortega, Zaragoza, Espagne
(3) Servicio De Urgencias. Hospital Del Rio Hortega, Valladolid, Espagne
(4) Cs Reina Sofía. Tordesillas., Valladolid, Espagne
(5) cs Laguna De Duero., Valladolid, Espagne
(6) Cs De Sardoma, Vigo, Espagne
(7) Cs Nava De La Asunción., Valladolid, Espagne
(8) servicio De Digestivo. Hospital Clínico Universitario De Valladolid, Valladolid, Espagne
(9) Scs La Victoria, Gapvae.ervicio De Digestivo. Hospital Clínico Universitario De Valladolid, Valladolid, Espagne
(10) Semfyc International, Valladolid, Espagne

Context: Gender-based violence (GBV) is a major public health issue with severe consequences for women's physical, mental, and social well-being. Primary Health Care (PHC) is a key entry point for prevention, early detection, and coordinated management of GBV. Spain has developed a strong legal, policy, and institutional framework to support health-sector responses, yet the extent and consistency of PHC implementation remain uneven across regions.

Objectives: To map and synthesize existing evidence on GBV detection and management strategies within PHC and emergency health services in Spain, identifying best practices, barriers, enablers, and gaps requiring further investigation.

Methods: A scoping review was conducted following the Arksey and O'Malley framework and PRISMA-ScR guidelines. Literature published between 2006 and 2024 was searched in PubMed, Scopus, ScienceDirect, and Web of Science, complemented by grey literature from institutional repositories and national observatories. Studies addressing GBV detection, clinical management, or professional training in Spanish PHC or emergency settings were included. Data were extracted and synthesized thematically, integrating quantitative and qualitative evidence.

Results: Of 869 records identified, 76 studies and 20 grey literature sources met the inclusion criteria, including 13 Good Practices officially recognized by the Spanish National Health System. Evidence shows that standardized protocols, validated screening tools, structured training, and intersectoral coordination improve detection, documentation, and referral. However, implementation varies widely among autonomous communities. Persistent barriers include limited consultation time, insufficient training, inconsistent data recording, and fragmented coordination. Vulnerable groups—such as adolescents, migrant women, and Roma women—remain underserved, and few studies evaluate long-term outcomes or sustainability of interventions.

Discussion: Findings illustrate the progressive institutionalization of GBV responses within Spanish PHC, supported by national policies and mechanisms for knowledge translation (Catalogue of Good Practices). Successful models emphasize socio-educational interventions, improved information systems, training networks, and intersectoral collaboration. Nevertheless, heterogeneity in implementation and limited evaluation highlight the need to strengthen monitoring, integrate GBV indicators into electronic health systems, and ensure sustained professional training.

Conclusion: Spain has made substantial progress in integrating GBV prevention and care into PHC, yet inconsistent implementation and limited evaluation hinder system-wide impact. Enhancing coordination, data integration, and long-term assessment is essential to ensure equitable, effective, and sustainable GBV responses across regions.

ID 1183- Development of a digital health tool (Eu-Decido) to support Brazilian women experiencing intimate partner violence in primary healthcare

Marcos SIGNORELLI [1] , Acacia LIMA [1], Vanessa LUCCHESI [2], Emanueli DA COSTA [1], Marcia LOPES [3], Mara DOS SANTOS [4], Stephanie PEREIRA [5], Ana Flavia D'OLIVEIRA [5], Dabney P. EVANS [6], Lilia SCHRAIBER [5]

(1) Federal University Of Parana, Curitiba, Brésil
(2) Federal University Of Parana, Paranagua, Brésil
(3) House Of The Brazilian Woman, Campo Grande, Brésil
(4) Federal University Of Mato Grosso Do Sul, Campo Grande, Brésil
(5) University Of Sao Paulo, Sao Paulo, Brésil
(6) Emory University, Atlanta, États-Unis

Context: Intimate partner violence (IPV) is a public health problem, and primary healthcare (PHC) professionals are key in support women. Digital health tools can assist professionals in developing safety planning for women, but studies on such tools are scarce.

Objectives: We developed and assessed the feasibility of a digital health tool (app and website) to support decision-making and safety planning for Brazilian women experiencing IPV in PHC settings.

Methods: We previously developed a prototype named "Eu-Decido" (I-Decide) with survivors and professionals from a specialized IPV service in XXXXXX Brazil. In the current phase, we evaluated Eu-Decido through qualitative research with participants from two PHC Units. We conducted 17 in-depth interviews with women and two Focus Groups Discussions with PHC professionals (n=31), including doctors, nurses and allied health staff. Data were recorded, transcribed, coded and subjected to thematic analysis through data triangulation and feminist/gender theoretical perspectives.

Results: Participants indicated that Eu-Decido is highly feasible for PHC settings, highlighting important issues: 1) PHC teams often lack confidence in caring for abused women, and Eu-Decido provided them with reliable information to develop a safety plan for their patients; 2) women found the tool viable for supporting their decision-making, helping them understand their exposure to IPV and assess their risks; 3) both groups felt that Eu-Decido provides updated information on women's rights and available help, though user safety measures need improvement, as many partners monitor women's devices.

Discussion: PHC is universal and accessible across all 5,570 Brazilian municipalities and is considered the main gateway to care for abused women. Eu-Decido can be a valuable support tool for PHC professionals. However, refinements and additional research are needed to expand the applicability of our local study to the broader Brazilian context.

Conclusion: The perspectives of professionals and the needs of women in PHC are informing the refinement of the current prototype, resulting in version 2.0. This new version will be submitted to a longitudinal evaluation with 400 women from across Brazil. If proven efficient and safe, the plan is for Eu-Decido to be made available free of charge for national use, supporting PHC professionals in providing comprehensive care for women experiencing IPV.

ID 412- Structural Determinants of Women's Attitudes Toward Intimate Partner Violence

Çiğdem DELICE SEZGIN, Oğulcan ÇÖME, Tolga GÜNVAR

Dokuz Eylül University Faculty Of Medicine, Department Of Family Medicine, Izmır, Türkiye

Context: Gender norms and structural inequalities strongly influence women's perceptions of intimate partner violence (IPV). Understanding how gender role attitudes shape responses to IPV is essential for informing preventive public health strategies.

Objectives: To examine the relationship between women's gender role attitudes and their attitudes toward IPV and assess how sociodemographic characteristics and generational differences influence these perceptions.

Methods: This cross-sectional study included 1,091 women aged ≥18 years registered at XXX University Family Health Centers. Participants were randomly selected and stratified by generational cohort (X, Y, Z). Data were collected using a sociodemographic questionnaire, the Gender Roles Attitude Scale (GRAS), and the ISKEBE Attitude Scale. Descriptive statistics, Spearman correlations, Mann–Whitney U/Kruskal–Wallis tests, linear regression, and logistic regression analyses were performed (α=0.05).

Results: Participants' mean age was 36.5 years; 75.2% held a university degree and 68.4% were employed. Lifetime IPV exposure included physical (16.5%), sexual (15.3%), psychological (41.4%), and economic violence (18.9%). Higher GRAS and ISKEBE scores were associated with higher education, employment, adequate income, and younger generations (all $p<0.001$). GRAS and ISKEBE scores showed moderate-to-strong positive correlations (ρ=0.52–0.69). Regression analyses identified

education and generational cohort as the strongest predictors of egalitarian and anti-violence attitudes. Logistic regression showed that low income, lower education, and being separated or without a partner increased the risk of IPV, whereas attitudinal scales did not independently predict exposure.

Discussion: Education, employment and higher economic status were consistently associated with more egalitarian and violence-rejecting attitudes, while Generation Z women displayed the strongest opposition to IPV. Exposure analyses showed that psychological and economic violence are easily normalized, whereas witnessing violence significantly shaped identity- and body-related attitudinal subscales. Marital status and economic security emerged as key predictors across all violence types, highlighting their protective roles. The lack of a direct association between attitudinal scales and IPV exposure underscores the complexity of contextual and intergenerational influences.

Conclusion: Women's attitudes toward IPV and gender equality are shaped primarily by structural determinants—education, economic status, and generational context. Younger generations show stronger egalitarian and anti-violence orientations, highlighting the need for policies that enhance educational opportunities, financial empowerment, and generational engagement to reduce IPV.

ID 312- My trauma can be my superpower – a qualitative study of GP survivors' experiences working with domestic and family violence survivors.

Jennifer NEIL [(1)] , Clare DELANY [(2)], Elizabeth MCLINDON [(1)], Kelsey HEGARTY [(1)]

(1) Department Of General Practice And Primary Care, The University Of Melbourne, Melbourne, Australie
(2) Department Of Medical Education, The University Of Melbourne, Melbourne, Australie

Context: Domestic and family violence (DFV) is common both in the community with one in four females subjected to intimate partner violence and one in two adults being survivors of child abuse. It is also common amongst healthcare workers including doctors. DFV survivors frequently present to primary care where general practitioners (GPs) who are survivors of DFV are likely to encounter them. General practice is unique as GPs look after whole families and have continuity of care. There have been no qualitative studies in general practice focusing on survivor GPs experiences when working with survivors of DFV.

Objectives: What are the experiences of survivors GPs when working with survivors of DFV?

Methods: This study used a phenomenological qualitative approach to gain a deep understanding of [country] GP DFV survivors' experiences when working with DFV survivors in their clinics. Participants were [country] GPs who self-identified as survivors of all forms of DFV. Purposive sampling was used to recruit participants from two [country] GP online groups. Semi-structured interviews took place and were audio recorded and transcribed verbatim. Reflexive thematic analysis was undertaken.

Results: Participants (20) were female and worked in a wide range of locations throughout [country]. All participants saw survivors of DFV in their clinics, and most saw more than their colleagues. Four themes were identified: Identifying with DFV survivors; wearing a cloak of professionalism; my experiences are my superpower to support survivors; going above and beyond.

Discussion: This is the first qualitative study to focus on survivor GPs experiences when working with DFV survivors. Secondary re-traumatisation was common, particularly when participants identified with DFV survivors. Despite this, participants experienced post-traumatic growth and were able to better identify, work with and advocate for their survivor patients because of their own DFV experiences. Views on reciprocal sharing were mixed due to the tension between remaining professional and improving rapport with survivor patients, an area which remains controversial amongst health professionals.

Conclusion: Survivor GPs would benefit from support due to their high case-load of DFV and to improve well-being. Further research is recommended to investigate how best to support survivors GPs.

ID 62- Testing culturally competent domestic violence and abuse management for South Asian women in Australian primary care: HARMONY a cluster randomised trial

Angela TAFT [1] , Felicity YOUNG [1], Kelsey HEGARTY [2], Jane YELLAND [3], Danielle MAZZA [4], Douglas BOYLE [2], Richard NORMAN [5], Claudia GARCIA-MORENO [6], Cattram NGUYEN [3], Xia LI [1]

(1) La Trobe University, Bundoora, Australie
(2) University Of Melbourne, Parkville, Australie
(3) Murdoch Childrens Research Institute, Parkville, Australie
(4) Monash University, Clayton, Australie
(5) Curtin University, Perth, Australie
(6) World Health Org, Geneva, Australie

Context: Immigrant women can experience high rates of domestic violence and abuse (DVA) and migration trauma and may seek help for DVA related mental and physical ill-health in primary care in diaspora countries. General practitioners (GPs) have limited DVA training or support to manage culturally-competent DVA primary care practice.

Objectives: HARMONY aimed to increase culturally-competent DVA identification and referral among all, but especially South-Asian women, attending Australian GP clinics.

Methods: 24 GP clinics recruited among South-Asian communities in Northwest and Southeast XXX, for a pragmatic waitlisted cluster trial, following CONSORT guidelines. Eligible clinics (i) employed ≥1 South Asian GPs, (ii) used 1 of 2 electronic software programs and (iii) agreed to anonymised, aggregated data extraction. Clinics randomised using computer minimisation. HARMONY's intervention comprised a) GP DVA educator and bilingual South-Asian DVA advocate co-delivering accredited culturally-competent DVA training, and b) 12 months follow-up support by DVA advocate to intervention clinics. Comparison clinics offered routine care. We extracted aggregated, anonymised routine data for primary outcomes of DVA identification and referral, and South-Asian ethnicity, at 12 and 15 months. Adjusted, intention-to-treat analysis using Poisson regression.

Results: Five of 24 GP clinics withdrew before the trial began, as COVID-19 impacted. At baseline, GPs documented DVA in 0.6% of non-South Asian, but 0.4% South-Asian women (all patients=48,362), and none recorded DVA referrals. Identification trended up in both arms, but we found no evidence of difference in DVA identification at 12 months in Intervention (0.98%) vs Comparison (0.88%), IRR 1.17 (0.60 to 2.28) or 15 months Intervention 1.01% vs Comparison 0.96%, IRR 1.17 (0.60 – 2.67). Referrals were rare (Int 14/252 vs Comp 6/199). 6/14 Intervention referrals were South-Asian women. No adverse events were recorded.

Discussion: HARMONY's model of care drew on culturally safe DVA best practice and previous GP DVA trials. We found no evidence for a significant effect on DVA identification or referral in a challenging COVID-19 pandemic. We did find that providing GP clinics serving migrant/refugee populations with cross-cultural training and support motivates improvement from a very low DVA identification rate.

Conclusion: In an increasingly diverse world, the HARMONY model of culturally safe DVA care should be further tested.

ID 47- Systematic screening of intimate partner violence among female patients hospitalized at Nîmes University Hospital

Iris BOUCHAYER [1] , Sylvie RIPART [2], Jean-Yves LEFRANT [3]

(1) Médecine Générale, Montpellier Univ, Montpellier, France
(2) Pôle Mère Enfants, Montpellier Univ, Chu Nîmes, Nîmes, France
(3) Imagine, Ur-Um 107, Montpellier Univ, Pôle Anesthésie Réanimation Douleur Urgences, Chu Nîmes, Nîmes, France

Context: WHO defines Intimate partner violence (IPV) as any behaviour within an intimate relationship that causes physical, sexual or psychological harm. In France, in 2023, we estimate

271 000 victims of IPV, 85% of whom were women. Since 2019, The French National Authority for Health recommends sytematic screening for violence due to its significant impact on the overall health of victims. The hospital is an ideal place to conduct this screening, offering a safe environment, a multidisciplinary care and an access to facilities such as La Maison des Femmes for women victims of violence.

Objectives: The main outcom of this study was to investigate the prevalence of IPV among female patients hospitalized at xxx University Hospital using the self-questionnaire WAST.

Methods: This was a single-center, cross-sectional observational study conducted during two 48h hours study sessions in March and April 2025. Any woman over 18, who had been in a previous relationship, spoke French, was able to read in French and non opposing after informations was eligible to participate.

Results: 126 women were included with a participation rate of 70 %. The prevalence of women victims of intimate partner violence recently was estimated at 1,6%.

Discussion: Our prevalence (1,6%) is lower than other french studies using the questionnaire WAST, but concurrently the average age of our patients was higher meaning that there may have been a recruitment bias. Even if the WAST questionnaire was an excellent tool to screen recent events and to act quickly , we realized through this study that we were missing all the women victims of past IPV events. Yet we know now that domestic violence, regardless of when it occurred, has a significant impact on overall health. Looking ahead, we would like to expend the screening to all patients, male and female, for all cases of IPV through their lifetime and to conduct a multicenter study.

Conclusion: Our study showed that at least one woman recently victim of IPV is hospitalized each day at xxxUniversity Hospital. It seems essential to encourage the healthcare workers to systematically screen all patients for IPV and to make it an integral part of our care habits.

Wait… did you say weight?

ID 2260- Weight stigma experienced or perceived by adult patients with obesity in primary care: A mixed-methods systematic review

Marion LAMORT-BOUCHÉ [(1)] , Romane BORDET [(2)], Fanny VADUREL [(2)], Emmanuelle GUIMARAES [(2)], Cyrielle CAUSSY [(3)], Emmanuel DISSE [(3)], Laurent LETRILLIART [(1)]

(1) Reshape U1290 Inserm Université Claude Bernard Lyon 1, Lyon, France
(2) Collège Universitaire De Médecine Générale Université Claude Bernard Lyon 1, Lyon, France
(3) Laboratoire Carmen, Inserm U1060, Université Claude Bernard Lyon 1, Lyon, France

Context: Weight stigma is widespread across all healthcare settings, where it has been shown to contribute to poor physical health outcomes, as well as to the persistence of obesity. Its impact in primary care setting deserves to be detailed.

Objectives: To synthesize evidence on weight stigma experienced or perceived by adults living with obesity in primary care, based on patient reports or data obtained from sources external to both patient and caregiver.

Methods: We conducted a mixed-methods systematic review using a convergent integrated design to combine quantitative and qualitative evidence through thematic synthesis. Five databases (PubMed, PsycInfo, Web of Science, Embase, Cairn) and grey literature were searched in 11/2025. Study selection, data extraction, and quality appraisal (MMAT 2018) were performed independently by two reviewers. Adult participants (≥18 years) with obesity (BMI ≥30 kg/m^2) were included if experiences of weight stigma were investigated within primary care settings.

Results: Twenty-five studies met the inclusion criteria (13 qualitative, 11 quantitative, 1 mixed). Weight stigma emerged at three levels: (1) in patient–provider relationships, manifested through negative assumptions, disrespectful communication, non-verbal cues, and anticipation of judgment; (2) in obesity management, characterized by either insufficient or excessive

focus on weight, oversimplified lifestyle advice, lack of referral and follow-up, limited provider training, and communication issues; and (3) in overall care beyond obesity, with frequent attribution of any health problem to excess weight, perceived lower quality of general care, and lower screening rates for cancers. Despite widespread negative experiences, several studies also reported positive care interactions and supportive relationships.

Discussion: This review suggests a need to develop research on weight stigma from men's perpective, but also from patients who are not engaged in care. It might also be interesting to study weight stigma more extensively, through direct or indirect observation of consultations or through analysis of health databases.

Conclusion: Weight stigma in primary care affects not only weight management discussions but also overall healthcare delivery for patients living with obesity. While interventions to reduce weight stigma in clinical settings appear relevant, stigma frequently arises upstream of medical interactions and reflects broader societal attitudes. Comprehensive strategies targeting individual, educational, and structural determinants of stigma are warranted.

ID 2211- Relationship Between Nutritional Status and Systemic Immune–Inflammation Indices Across BMI Categories

Aysen KUTAN FENERCIOGLU [(1)] , Hafize UZUN [(2)], Abdulhalim SENYIGIT [(3)], Gunay CAN [(4)]

(1) Department Of Family Medicine, Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Istanbul, Türkiye
(2) Department Of Medical Biochemistry, Faculty Of Medicine, Istanbul Atlas University, Istanbul, Türkiye
(3) Department Of Internal Medicine, Faculty Of Medicine, Istanbul Atlas University, Istanbul, Türkiye
(4) Department Of Public Health, Cerrahpasa Medical Faculty, Istanbul University-Cerrahpasa, Istanbul, Türkiye

Context: This original article highlights the association between nutritional status and systemic inflammation across different BMI categories.

Objectives: This study aimed to determine the relationship between nutritional status and systemic inflammation using four validated nutrition indices—Hemoglobin, Albumin, Lymphocyte, and Platelet (HALP) score, Prognostic Nutritional Index (PNI), Controlling Nutritional Status (CONUT) score, and Nutritional Risk Index (NRI)—and three immune-inflammation biomarkers—Systemic Immune-Inflammation Index (SII), neutrophil-to-lymphocyte ratio (NLR), and platelet-to-lymphocyte ratio (PLR)—in healthy adults with varying body mass index (BMI) levels.

Methods: This retrospective study included 290 clinically healthy adults aged 18–60 years, categorized by BMI. Individuals with chronic diseases, medication use, or morbid obesity (BMI ≥ 40 kg/m²) were excluded. Nutrition scores (HALP, PNI, NRI, CONUT) and systemic immune-inflammation indices (SII, NLR, PLR) were calculated from laboratory data. For the comparisons of SII, PLR, NLR, PNI, HALP, NRI, and CONUT values between groups, age was adjusted for, and an ANCOVA test was performed.

Results: Among the systemic immune-inflammation indices, SII and NLR were significantly higher in both the overweight and obesity groups. The CONUT score, a negative indicator of nutritional status, demonstrated positive correlations with SII, NLR, and PLR in the overweight group and with PLR in the obesity group. Although PNI showed significant inverse correlations with SII, PLR, and NLR in both groups, the mean PNI values remained above 50, indicating overall normal nutritional status in the study population. HALP was inversely correlated with SII, PLR, and NLR in both groups.

Discussion: Unlike many prior studies that focused on hospitalized or chronically ill patients, our inclusion of individuals without known chronic diseases allows for a clearer evaluation of subclinical inflammatory and nutritional dynamics related to adiposity. The use of a wide array of validated indices—both nutritional and inflammatory—provides a comprehensive and multidimensional assessment of immune-nutritional interactions in the context of increasing BMI.

Conclusion: Our study demonstrates that higher BMI is associated with increased levels of systemic immune-inflammatory markers. Among the nutritional indices examined, the HALP score appears to reflect the inverse relationship between nutrition and inflammation most effectively. This index may be useful for early identification of

subclinical inflammation in overweight and/or obesity populations

ID 2040- Obesity; an innovative interprofessional approach in a region

Nynke SCHERPBIER

University Medical Centre Groningen, Groningen, Pays-Bas

Context: The prevalence of overweight and obesity is increasing worldwide and is associated with cardiovascular morbidity, musculoskeletal complaints, depression, and reduced societal participation. In the region of XXXX, the prevalence of overweight was 57% and that of obesity 30% in 2024. These figures are strongly influenced by social determinants of health. Addressing obesity therefore requires an interprofessional approach that extends beyond healthcare into prevention, social support and education. Our aim is to develop and implement an integrated regional approach to overweight and obesity that connects primary care, social services, citizens, and interprofessional education.

Methods: In the region of XXXX, a unique funding opportunity enabled the development of a one-year program, with the prospect of continuation for three additional years. Starting March 1st, 2026, the program consists of three interconnected components in a region with over 500.000 inhabitants: a. A managed care approach initiated in all willing general practices, involving general practitioners, practice assistants, lifestyle coaches, and social workers. b. Vouchers for inhabitants to support changes in their living environment that promote a healthy lifestyle. c. Interprofessional community-based education involving students from social work, sports, nursing, physiotherapy, dietetics, and medical school.

Originality: To our knowledge, this is the first initiative in which general practice, social care, citizens and education are systematically connected at a regional level around the theme of overweight and obesity.

Lessons learned and future implication: Municipalities aim to fulfil their statutory preventive tasks; social work seeks a stronger role in obesity guidance; general practitioners wish to identify and appropriately refer patients while addressing medical causes where needed. Citizens emphasize

Discussion: Societal causes cannot be solved by healthcare alone. However, connecting the various stakeholders with varying goals and funding is very difficult.

Conclusion: Preparing this program on obesity highlighted the complexity of truly understanding and integrating diverse perspectives. Nevertheless, by maintaining a shared societal goal, a comprehensive regional approach was achieved, including a key role for general practice. The first findings can be shared at WONCA2026.

ID 1469- Obesity and Weight Loss: Comparison of Lived Experiences Before Bariatric Surgery and During the First Postoperative Year Within the Same Cohort — An Anthropological Contribution to Primary Care

Meïdi KOUYA, Philippe CORNET, Judith ARON-WISNEWSKY

Sorbonne-Université, Paris, France

Context: Recent epidemiological projections, including Lancet reports, indicate that obesity continues to rise globally and in Europe, where nearly 60% of adults are overweight or obese. Weight-related stigma from healthcare providers has been strongly associated with degraded care experiences and negative health outcomes. Understanding the lived experience of obesity and weight loss is therefore essential to reduce clinician bias and to support patients effectively through the physical, psychological, and social transformations associated with weight-loss interventions, particularly in the era of emerging pharmacological obesity treatments.

Objectives: To explore patients' lived experience before bariatric surgery and during the first postoperative year, and to identify practical recommendations directly suggested by patients to inform care in primary care settings.

Methods: A longitudinal qualitative study in the Île-de-France region included 17 adults. Semi-structured interviews were conducted preoperatively in 2024 and at one-year post-operation in 2025. Interviews were audio-recorded, anonymized, and transcribed verbatim for secure analysis. Inductive thematic analysis followed Braun & Clarke's methodology, with manual coding and double reading. Rigor was ensured using Yong's COREQ-32 checklist. Ethics approval and GDPR compliance were obtained. To date, 16 of the 17 patients have been followed up, with the final patient expected to be included.

Results: Preoperatively, three main themes emerged: suffering related to social and medical judgment, ambivalent relationship with body and food, and mixed anticipation of surgery combining hope and anxiety. At one year postoperatively, patients reported deep improvements in self-esteem, a generally positive experience, and significant changes in social, familial, and professional interactions. A persistent need for individualized, holistic support remained.

Discussion: These findings highlight the limitations of purely biomedical follow-up. Patient narratives reveal how physical, psychological, and social transformations profoundly affect experiences of obesity and weight loss. They underscore the importance of empathetic, patient-centered approaches in primary care, and illustrate how clinicians' awareness of stigma and subjective experience can shape care outcomes.

Conclusion: The study provides practical insights directly suggested by patients. Impactful verbatims and patient-derived recommendations could help improve support for those undergoing bariatric surgery, and enrich the broader care of patients with obesity within primary care practice. Keywords: Obesity; Bariatric Surgery; Family Practice; Qualitative Research; Body Image;

ID 764- The association between perceived stress and abdominal obesity in Korean adults: 2022–2023 Korea national health and nutrition examination survey

Minji BAK

Department Of Family Medicine, Seoul National University Hospital, Seoul, Corée, République de

Context: Stress is a prevalent issue in modern society. Abdominal obesity is a key component of metabolic disease, and a major driving factor of all-cause and cardiovascular mortality. Although previous studies have linked stress with obesity or metabolic disorder, specific evidence regarding stress and abdominal obesity in recent nationally representative Korean populations remains limited.

Objectives: To investigate the association between the level of perceived stress and the risk of abdominal obesity among Korean adults, and to determine whether this association according to sex.

Methods: This cross-sectional study included 9,525 Korean adults aged 19 years or older (4,151 males and 5,374 females) who participated in the Korea National Health and Nutrition Examination Survey conducted from 2022 to 2023. Perceived stress level was assessed via a self-administered questionnaire. Abdominal obesity was defined as waist circumference ≥90 cm in males and ≥85 cm in females, based on sex-specific cutoffs according to Korean adult criteria. Weighted multivariable logistic regression analysis adjusting for age, sex, socioeconomic factors, and health behaviors was utilized to evaluate the association between perceived stress and abdominal obesity.

Results: In a weighted multivariable logistic regression analysis adjusting for age, sex, socioeconomic factors, and health behaviors, the high-stress group had higher odds of abdominal obesity than the low-stress group (OR 1.34; 95% CI 1.20–1.50; $p<0.001$). The association also persisted when stratified by sex. Among males, the odds ratio was 1.35 (95% CI 1.15–1.57; $p<0.001$), and among females, the odds ratio was 1.37 (95% CI 1.16–1.63; $p<0.001$).

Discussion: Higher levels of perceived stress may contribute to an increased risk of abdominal obesity in Korean adults. This finding aligns with the established biological mechanisms linking stress and visceral fat accumulation by increasing cortisol secretion via the hypothalamic–pituitary–adrenal axis, as well as behavioral pathways including overeating and sedentary lifestyle.

Conclusion: Among Korean adults, higher levels of perceived stress were associated with abdominal obesity. Similar odds ratios in males and females suggest that stress may influence abdominal fat accumulation regardless of sex. These findings highlight stress management as an important strategy for the prevention of abdominal obesity and metabolic diseases in Korean primary care.

ID 434- Using Theatre to Tackle Weight Stigma in Primary Care: A Participatory Study on Empathy and Professional Awareness

Jan BARAN

Dmg Lille, Lille, France

Context: Weight-related stigma negatively affects the doctor–patient relationship by reducing trust, empathy, and quality of communication. Health professionals may hold implicit biases that hinder patient-centred care, yet conventional training rarely addresses this issue effectively. Participatory and arts-based methods, particularly theatre, have shown promise in engaging professionals emotionally and reflectively. However, evidence on theatre as a tool to address weight stigma in primary care remains limited.

Objectives: To co-design, implement, and evaluate a participatory theatre-based intervention aimed at increasing awareness of weight stigma and strengthening empathy among primary care professionals.

Methods: This participatory study was conducted within a French community health network (CPTS) and comprised three stages: (1) a systematic literature review on theatre-based interventions targeting healthcare communication and the doctor–patient relationship; (2) co-construction of a play based on lived experiences shared by patients, healthcare workers, and community partners, followed by a local performance in June 2024; (3) quantitative evaluation of empathy using the Jefferson Scale of Physician Empathy (JSPE), administered to attending professionals before the performance, immediately after, and three months later. Descriptive and comparative statistics were used to analyse changes in JSPE scores over time.

Results: The literature review identified 16 studies, most reporting short-term improvements in empathy, attitudes, or communication skills following theatre interventions. The co-developed play was attended by 74 participants, including general practitioners, nurses, pharmacists, dietitians, and allied health professionals, as well as community members with lived experience. Among the 63 professionals who completed the JSPE, scores increased from 111.36 at baseline to 118.66 immediately after the play (p=0.001) and remained elevated at 116.50 three months later (p=0.015).

Discussion: The study drew strength from its participatory development process and from the use of a validated empathy scale. The positive shift in empathy scores indicates that theatre may facilitate emotional resonance and critical reflection among healthcare professionals. The absence of a control group is a limit.

Conclusion: Participatory theatre is a promising, transferable approach to raising awareness of weight stigma and fostering empathy among primary care professionals. Its sustained effects at three months support its potential as a tool for continuous professional development and for improving patient-centred care in community settings.

Addictions

ID 1651- How do parents of adolescents understand and conceptualize video game addiction?

Vladimir DRUEL, Margaux GAILLARD, Grégory BINIASZ, Aurore PALMARO, Dupouy JULIE, Blandine DARCHY

Département Universitaire De Médecine Générale De Toulouse, Toulouse, France

Context: With 83% of adolescents playing video games weekly, general practitioners are increasingly confronted with issues related to gaming among young people. Despite the inclusion of diagnostic criteria for gaming disorder in the ICD-11 in 2018, little is known about how parents perceive this condition. In the context of the widespread presence of video games and persistent parental concerns, we identified a lack of studies exploring parents' representations of video game addiction.

Objectives: To explore the representations of video game addiction by parents of adolescents.

Methods: We conducted a qualitative study using thematic analysis of semi-structured individual interviews with parents of gaming and non-gaming adolescents. Sampling followed a purposive theoretical strategy. Participants were recruited through information posters in the general practice waiting room, at a youth center, outside a school, and via social media. Data were analyzed thematically, associated with data triangulation.

Results: Twelve interviews were conducted, including two after reaching thematic saturation. Parents expressed ambivalence between recognizing the social and recreational benefits of video games and fearing the risks of addiction. While many reported concerns about potential negative effects on their adolescent's health and behavior, they also described challenges in supervising gaming, which was often perceived as excessive. Parental representations were elaborated by their own gaming experiences or by media narratives. Video game addiction was commonly associated with loss of control over playtime, preoccupation with gaming, and excessive use that disrupts daily professional, social, or family functioning.

Discussion: This study underlines the need to clarify diagnostic criteria for gaming disorder to better distinguish "excessive use" from a true pathological condition. Its main strengths lie in its originality and adherence to methodology. Limitations include potential recruitment bias linked to the use of QR codes, favoring participants comfortable with digital tools, and the voluntary nature of participation.

Conclusion: Parents demonstrated awareness of the risks associated with problematic video game use. The study suggests several areas for improvement, including providing training and support for parents and incorporating validated diagnostic tools into the routine medical monitoring of adolescents in general practice.

ID 1428- Psychoactive substance use among university students: a cross-sectional study

Tan-Trung PHAN, Félicia MEUNIER, Timoté JOANNES

Département Universitaire D'enseignement Et De Recherche En Médecine Générale, Université Paris-Est Créteil, Créteil, France

Context: General practitioners (GPs) play a central role in preventing addictions and screening for psychoactive substance (PAS) use among young adults. Early, systematic detection of commonly used PAS is recommended, yet screening is often directed only toward patients perceived as at risk. Existing research at University XXX has focused exclusively on medical students, leaving PAS use across other academic disciplines unexplored.

Objectives: The primary objective was to assess the prevalence of PAS use among students from all disciplines at University XXX. The secondary objective was to identify factors associated with the use of alcohol, tobacco, and cannabis.

Methods: A cross-sectional quantitative study was conducted between November 2022 and April 2023 among all adult students at University XXX. An anonymous online questionnaire, disseminated via email and social media, collected sociodemographic characteristics and current PAS use. Descriptive statistics and univariate analyses were performed to identify factors associated with PAS use.

Results: Among the 1498 responses received, 1475 were included. Participants had a median age of 20 years, and 75.7% were women. The most commonly used PAS were alcohol (36.7%), tobacco (12%), and cannabis (7%). Factors associated with alcohol use included male sex (p<0.001), living independently (p<0.001), paid employment (p=0.01), and regular physical activity (p<0.001). Factors associated with tobacco use included living independently (p<0.01), paid employment (p<0.001), and clear anxiety symptoms (p<0.001). Factors associated with cannabis use included male sex (p<0.001) and paid employment (p<0.001).

Discussion: This study gathered a large, multidisciplinary student sample, providing valuable insight into PAS use across academic fields. Although selection and reporting biases cannot be excluded, the findings may help GPs prioritize which PAS to screen for in student populations, either routinely or based on patient profiles.

Conclusion: PAS use is common among university students and varies with demographic, psychosocial, and lifestyle factors. These results underscore the importance of targeted screening strategies in general practice to enhance early detection and brief intervention among young adults.

ID 648- Impact du sémaglutide sur les dépenses en alcool et tabac : comparaison entre utilisateurs et non-utilisateurs

Melissa AKERIB [(1)], Gilles PETIT [(2)] , Timothy ARNAUT [(3)], Katya KAZANTSEVA [(4)], Kajsa KVIST [(3)], Bríain Ó HARTAIGH [(5)]

(1) Novo Nordisk, Puteaux, France
(2) Msp La Souterraine, La Souterraine, France
(3) Novo Nordisk, Soborg, Danemark
(4) Market Track Lcc, Chicago, États-Unis
(5) Novo Nordisk, Plainsboro, États-Unis

Context: Despite increasing awareness of semaglutide use for weight management worldwide, the broader economic, psychological, and behavioral impacts of semaglutide are less well characterized. In the limited evidence available, once-weekly semaglutide has been associated with reduced alcohol and tobacco consumption.

Objectives: Using a US consumer database, we aimed to investigate this hypothesis, comparing household spending on groceries, alcohol, and tobacco between people using semaglutide for weight management and those not using a glucagon-like peptide-1 receptor agonist (GLP-1RA).

Methods: Data came from two 12-month periods before each of five quarterly survey waves (Apr 2024–Apr 2025) in Numerator's US omnichannel panel (>200,000 households). Grocery (including alcohol) and tobacco spending were captured via scanned receipts and quarterly surveys with demographics, medication use, and behavior. Households were classified as having at least one branded semaglutide user for weight management or no GLP-1RA users based on surveys. For each wave, we computed the difference in year-over-year percent change in grocery spending between semaglutide and non-GLP-1RA households; mean differences across waves are reported in percentage points.

Results: As of April 2025, most participants were ≥45 years (S 74.6%; N 67.4%) and female (S 83.7%; N 76.3%). Race/ethnicity: White (S 71.5%; N 66.0%), Black (S 18.7%; N 13.8%), Hispanic (S 7.4%; N 14.6%). Household size was mainly one (S 19.6%; N 28.2%) or two (S 40.0%; N 35.0%); the top census division was South Atlantic (S 20.1%; N 22.7%). More semaglutide households had income ≥$125K (S 46.6%; N 38.3%). Current smokers: S 7.0%, N 8.3%; former smokers: S 19.2%, N 17.1%. Mean year-over-year grocery spending change was −1.1 percentage points for semaglutide versus non-GLP-1RA users, indicating relatively lower spending growth.

Discussion: Notably, there were greater mean change differences in spending on alcohol (−4.7% points) and tobacco products/accessories (−17.8% points) for semaglutide users.

Conclusion: The results of this analysis provide insights indicating that semaglutide use for weight management may be associated with reductions in the consumption of alcohol and tobacco products. More extensive behavioral studies are warranted to validate these findings.

Corresponding author: Timothy Arnaut, fmak@novonordisk.com

ID 771- The mediating effect of substance use in the path between childhood trauma and risky sexual behaviors among incarcerated women

Imen MLOUKI, Hend MASMOUDI, Aya AJMI BLOUT, Emna HARIZ, Sana EL MHAMDI

Preventive And Community Medicine Department, Faculty Of Medicine Of Monastir, University Hospital Of Mahdia, Mahdia, Tunisie

Context: Risky Sexual Behaviors (RSBs) are a significant public health concern leading to both short- and long-term reproductive health issues. Among incarcerated women, RSBs are highly prevalent and often linked to Adverse Childhood Experiences (ACEs) and Substance Use (SU).

Objectives: This study aimed to examine the associations between ACEs, SU, and RSBs among incarcerated women with a specific focus on the mediating role of SU in the path from ACEs to RSBs.

Methods: A cross-sectional study was conducted in July 2024 among a sample of incarcerated adult women in a correctional facility in XXX. We used the validated Arabic version of the Adverse Childhood Experiences International Questionnaire (ACE-IQ). The questionnaire was anonymous and participation was voluntary.

Results: A total of 165 female inmates completed the questionnaire with a mean age of 31 ± 14 years. Among them, 93.9% reported exposure to at least one ACE, with the most common category being childhood community violence (73.3%). Tobacco use was reported by 55.8% of participants, while one-third reported alcohol and drug consumption. RSBs, including unsafe sex and multiple partnerships, were reported by 36.4% of the women. We found that SU was a mediator in the path from childhood sexual abuse and community violence to RSBs.

Discussion: Unfortunately, few studies have examined this mediating effect worldwide, limiting our comparison. Across four recent studies conducted in the United States, researchers reported that higher ACEs were associated with increased alcohol use and a trend toward having more sexual partners. SU was found to fully mediate the relationship between childhood sexual abuse and sexually transmitted infections. Regarding developing countries, a pilot study conducted in Uganda found that ACEs and SU were predictors of RSB among emerging adults, although it did not examine the mediating factor effect.

Conclusion: Prevention strategies should prioritize trauma-informed interventions that integrate SU treatment as a core component of programs targeting sexual health and rehabilitation among incarcerated women.

ID 736- Impact of smartphone overuse on sleep quality and anxiety among young adults: a narrative review

Arij MARZOUGUI

Forensic Psychiatry Department, Razi Hospital, Mannouba, Tunisie

Context: Smartphone overuse has become a widespread phenomenon among young adults, raising concerns about its effects on sleep regulation and mental health. Excessive nighttime use is associated with delayed sleep onset, reduced sleep duration, and increased anxiety symptoms. Understanding these associations is essential for clinicians in primary care and mental health, who increasingly encounter patients presenting with sleep disturbances and anxiety related to digital habits.

Objectives: To synthesize current evidence on the association between problematic smartphone use, sleep quality, and anxiety among young adults, and to identify clinical patterns and intervention opportunities relevant for primary care.

Methods: A narrative review was conducted using peer-reviewed literature retrieved from PubMed, Google Scholar, and the Cochrane Library. Articles published from 2010 to 2025 were included. Eligible studies assessed smartphone use patterns, validated sleep measures, and anxiety outcomes in populations aged 18–35 years. Research from diverse international and low-to-middle-income settings was incorporated to ensure broad

applicability. Extracted material was organized thematically across physiological mechanisms, behavioral patterns, associated clinical consequences, and intervention strategies, allowing identification of consistent trends and practical insights.

Results: Evidence consistently shows that problematic smartphone use, particularly during evening hours, is associated with shorter sleep duration, poorer subjective sleep quality, and increased insomnia symptoms. Higher anxiety levels are also reported among frequent or compulsive smartphone users. Mechanisms include circadian disruption, cognitive-emotional hyperarousal, and maladaptive coping behaviors. Regional studies demonstrate high smartphone engagement and parallel associations with sleep and anxiety disturbances. Interventions such as structured sleep hygiene education, limitation of evening screen exposure, digital-use monitoring tools, and brief cognitive-behavioral strategies show promising effects on both sleep and anxiety outcomes.

Discussion: The literature consistently demonstrates that smartphone overuse negatively affects both sleep quality and anxiety among young adults. Recognizing these patterns is crucial for early intervention in primary care and mental health services. Behavioral strategies such as digital curfews, reduced screen exposure before bedtime, and psychoeducation on sleep hygiene show promising benefits. However, more research is needed to evaluate structured interventions tailored to digitally connected populations.

Conclusion: Addressing smartphone use can improve sleep quality and reduce anxiety, supporting better overall mental health outcomes in young adults.

ID 340- From First Contact to Care Trajectory: A Qualitative Study of Individuals Experiencing Problematic Gambling in Quebec (Canada)

Magaly BRODEUR, Gabrielle TODD, Niwezina Peace BUGINGO, Anne-Marie AUGER, Ariane GIRARD, Adèle MORVANNOU, Andrée-Anne LÉGARÉ, Jean-Daniel CARRIER, Catherine HUDON

Université De Sherbrooke, Sherbrooke, Canada

Context: In the Province of Quebec (Canada), the specialized helpline Gambling : Help and Referral (GHR) serves as the first point of contact for many individuals experiencing problematic gambling. In 2024, GHR received 8,060 calls and chats, 73% of which resulted in referrals to other services (e.g., primary care, addiction rehabilitation centers, tele-counseling, Gamblers Anonymous). However, little is known about the trajectory of these individuals following their initial contact with GHR.

Objectives: This study aimed to (1) describe the health and social service trajectories of individuals after contacting GHR, and (2) understand their care experiences and needs.

Methods: In this descriptive qualitative study, two semi-structured interviews, separated by 9-12 months intervals, were conducted with individuals (n = 46) at medium-to-high risk of problem gambling according to the Problem Gambling Severity Index (i.e, a score ≥ 3) who had contacted GHR within the past 3 months seeking help for this issue. We asked open-ended questions about their gambling habits and their experiences with health and social services to explore their care trajectories and identify future needs. Interviews were recorded and transcribed for thematic analysis with NVivo software.

Results: Semi-structured interviews revealed complex trajectories and highlighted major challenges related to accessibility, coordination and continuity of care. Results underscore the high prevalence of comorbidities associated with problematic gambling, including substance use (34.8%), depressive symptoms (32.6%), and alcohol use (23.9%). Data analysis is currently underway. Findings will be presented at the WONCA Europe Conference in June 2026.

Discussion: This study explores the complex care trajectories reported by individuals seeking help for gambling-related harm, with particular attention to issues of accessibility, service coordination, and continuity of care. Our findings are consistent with existing literature that emphasizes the difficulty of

maintaining continuous follow-up with individuals experiencing problematic gambling.

Conclusion: This study will shed new light on the challenges individuals with problematic gambling face along their care trajectories and offer insights to improve the health and social services targeting this population.

ID 70- Virtual patient simulation for undergraduates: usability and learning perceptions

Adèle MORVANNOU [1] , Youssef ALLAMI [2], Emilie GOSSELIN [3], Isabelle LEDOUX [3]

(1) Université De Sherbrooke, Montreal, Canada
(2) Université Laval, Laval, Canada
(3) Université De Sherbrooke, Sherbrooke, Canada

Context: Addictive disorders impose heavy burdens on health systems and society, yet university students in a range of disciplines, including future primary care physicians, often receive little structured preparation for working with such clients. Stigmatizing attitudes and limited clinical exposure reduce readiness for relational and ethical challenges in generalist practice. Experiential learning is critical for developing interpersonal skills that align with the core competencies of general practice medicine.

Objectives: This study aimed to evaluate the perceived usability and educational value of interactive virtual patient (VP) simulations, designed to train undergraduate and graduate students in interpersonal and reflective skills relevant to primary care settings involving addictions.

Methods: We employed a quantitative-dominant design, enriched by qualitative data. Participants completed three VP scenarios (alcohol, gambling, problematic internet use) that mimic first-contact. After each scenario they completed a 9-item questionnaire measuring usability (effectiveness, efficiency, satisfaction) and three open-ended questions exploring perceptions. Descriptive statistics, Kruskal-Wallis and Mann-Whitney tests analysed quantitative data and subgroup differences (scenario, gender, study level). Open responses underwent deductive thematic analysis following Braun and Clarke's approach (2006).

Results: A total of 92 responses were included (71 undergraduate, 21 master's). Usability ratings were high (means 2.17–2.74 on a 0–3 scale) with no major differences across scenarios; women rated the "emotional realism" item higher than men ($p = .016$). More advanced undergraduates rated the simulation as a more valuable addition to traditional teaching and showed greater willingness to reuse the tool (all ps $< .05$). Qualitative findings highlighted enhanced clinical reasoning, increased comfort with relational skills, realistic immersive experience and the safe "trial-and-error" environment. Many participants viewed the simulation as more engaging and practical than standard lectures or case studies.

Discussion: Early exposure to simulated interpersonal challenges in addictive behaviours can strengthen relational and reflective competencies essential to primary care.

Conclusion: High usability and positive perceptions support integrating such VP tools into curricula as accessible experiential learning that prepares students for the interpersonal and ethical demands of generalist practice.

Artificial intelligence

ID 2237- Assessment of clinical competence using AI-standardized clinical examination

Antonio LOPEZ [1] , Ludovic GABELIER [2], Clément PEYTAVI [1], Zeno LOI [2], Yves Marie PERS [2], Kevin YAUY [2]

(1) Dumg Montpellier, Montpellier, France
(2) Chru Montpellier, Montpellier, France

Context: Ensuring that health professionals meet verified thresholds of clinical competence is fundamental to societal expectations for safe, high-quality care. Competency-based medical education therefore requires assessment methods that are

frequent, scalable, and standardised across settings. However, Objective Structured Clinical Examinations (OSCEs)—the current reference standard—are resource-intensive and difficult to scale. AI-Standardized Clinical Examinations (ASCEs), using conversational virtual patients with automated scoring, have been proposed as a potential solution. Although a recent randomised trial demonstrated their effectiveness for training purposes, their validity as a scalable instrument for assessing clinical competence remains unknown.

Objectives: Can an AI-simulated, AI-scored clinical examination provide a valid and reliable assessment of clinical competence compared with a synchronised, human-graded national OSCE?

Methods: We conducted a multicentre prospective cohort study across six French medical schools. Among 948 eligible students, 586 completed a synchronised 10-station ASCE using conversational virtual patients approximately six weeks before undertaking the national 10-station OSCE. To assess scoring reliability, 20 ASCE transcripts were independently rated by eight expert examiners, yielding 143 completed transcript evaluations.

Results: ASCE performance was significantly associated with national OSCE scores (Spearman ρ = 0·57; P < 0·001; range across centres 0·48–0·72). Between-centre variance in ASCE scoring was minimal in mixed linear models (ICC = 0·006; model R^2 = 31%). Expert raters demonstrated strong inter-rater agreement for clinical skills (Krippendorff α = 0·80) and moderate agreement for communication and professional attitude (α = 0·70). Using the majority expert rating as the reference standard, automated scoring with GPT-4.1 did not differ significantly from expert assessment. Internal consistency was acceptable for a 10-station ASCE (Cronbach α = 0·67) and was projected to exceed 0·80 with 20 stations.

Discussion: ASCE scores were strong predictors of national OSCE performance, with consistent accuracy and negligible center influence. Secondary analyses showed acceptable reliability and expert agreement, and automated scoring matched expert performance, supporting ASCEs as scalable complements to traditional clinical competence assessment.

Conclusion: This work represents the first large-scale, multicentre validation study demonstrating that AI-based clinical examinations can provide standardised, reproducible, and scalable assessment of clinical competence, with potential implications for the development of digital infrastructures supporting large-scale clinical assessment, accreditation, and continuous professional evaluation.

Corresponding author: Antonio Lopez, antonio.lopez@umontpellier.fr

ID 1972- AI-Standardized Clinical Examination Training on OSCE Performance

Antonio LOPEZ [(1)] , Emma LAVIGNE [(1)], Yves Marie PERS [(2)], Kevin YAUY [(2)]

(1) Dumg Montpellier, Montpellier, France
(2) Chru Montpellier, Montpellier, France

Context: Objective Structured Clinical Examinations (OSCEs) are universally recognized as the gold standard for assessing clinical competence. However, they remain highly resource-intensive to organize, severely limiting the frequency and scalability of student training opportunities. While Generative Artificial Intelligence (AI) shows promise in medicine, randomized controlled trials evaluating its direct impact on high-stakes examination performance are lacking.

Objectives: This study evaluated the efficacy of an AI-Standardized Clinical Examination (ASCE) framework, powered by GPT-4 Turbo (DocSimulator™), on medical students' faculty OSCE performance. Secondary objectives assessed emotional readiness, exam-related stress, student satisfaction, and the perceived realism of the AI-generated patient encounters.

Methods: We conducted a single-blind, two-site randomized controlled trial including 247 early-clerkship medical students from November 2023 to January 2024. Participants were stratified by site and randomized to ASCE training (n=125) or standard training (n=122). The intervention group had 24/7 access to 16 expert-authored scenarios, enabling text-based interaction with virtual patients and immediate, detailed automated feedback. A

physical examination station (otoscopy) served as a control to ensure intervention specificity. The primary outcome was analyzed in the intention-to-treat population.

Results: The ASCE group achieved significantly higher OSCE scores compared to controls (median 11.4 vs. 10.7 out of 20; p=0.02; 95% CI 0 to 1.2). Notably, exam absenteeism was significantly lower in the intervention group (0.8% vs. 4.9%). Post-intervention data showed that ASCE improved emotional readiness (p<0.001) and reduced stress (p=0.02). In-session feedback indicated high acceptance: 80% of users felt they interacted with authentic patients, and 67% felt evaluated by teachers. Post-hoc analysis confirmed a positive dose-response relationship between platform engagement and exam scores (p=0.01).

Discussion: Although the score improvement was modest, suggesting subtle enhancements across multiple domains rather than a single skill, the marked improvement in emotional preparedness establishes ASCE as a powerful pedagogical adjunct. Unlike traditional methods constrained by standardized patient availability, ASCE offers scalable, standardized training. However, it cannot currently replace physical examination training.

Conclusion: ASCE training significantly enhances clinical reasoning and student confidence while addressing critical logistical challenges. As a scalable solution for diverse scenarios, AI-driven simulation represents a transformative, resource-efficient standard for modern medical education curricula.

Corresponding author: Antonio Lopez, antonio.lopez@umontpellier.fr

ID 748- Acceptability of using Artificial Intelligence for pre-diagnosis in teleconsultation : dual study involving General Practitioners and patients.

Pierre LE DOUARON, Gérard TIM

Dmg, Rennes, France

Context: The COVID-19 health crisis has had a positive impact on the rise of digital health tools. The healthcare system is increasingly centered on predictive, data-driven governance models enabled by Artificial Intelligence (AI). Numerous conversational agents, commonly referred to as chatbots, now guide patients online or by telephone throughout their care pathway. However, few studies have examined these chatbots, which could, in the near future, interact with patients prior to a teleconsultation and provide general practitioners (GPs) with a preliminary pre-diagnosis.

Objectives: This study aimed to evaluate the acceptability of AI-driven pre-diagnosis in teleconsultations by examining GPs' and patients' intention to use a health chatbot.

Methods: A quantitative study was conducted between July and December 2024 using two online self-administered questionnaires completed by GPs (recruited through professional networks) and patients (users of a teleconsultation platform). A research model was developed based on established measurement scales from the scientific literature, including the Technology Acceptance Model (Davis) and the Source Credibility framework (Ohanian).

Results: A total of 223 GPs and 249 patients participated in the study. Among physicians, most reported an intention to use the health chatbot. Attitude and social influence emerged as the two main factors positively influencing GPs' intention to use AI, whereas perceived risks exerted a negative effect. Among patients, the results highlight the central role of the chatbot's perceived humanity and perceived social presence. Social influence, self-efficacy, and perceived risks also significantly affected their intention to use the chatbot.

Discussion: A key strength of this study is its inclusion of the two main stakeholders in teleconsultation: patients and healthcare professionals. Both groups demonstrated an overall optimistic outlook regarding the future use of such chatbots, which aligns with findings from comparable studies outside the healthcare sector. GPs and patients alike value the human dimension of care, even in a teleconsultation context. Strengthening assurances around responsibility, integrity, security, and respect for the patient could help mitigate currently perceived risks.

Conclusion: The acceptability of using AI for pre-diagnosis in teleconsultations is high among both patients and GPs. Nevertheless, several limitations were identified, which should be carefully

addressed to ensure safe, effective, and responsible implementation of this technology.

Corresponding author: Pierre Le Douaron, pierre.ledouaron@univ-rennes.fr

ID 560- Proper use of generative IA in healthcare: the first guidance from the French National Authority for Health (HAS)

Paul VALOIS

Has, Paris, France

Context: Generative artificial intelligence (AI) systems are becoming increasingly widespread. These systems are being developed in the healthcare sector and have numerous applications in general practice. However, their use carries significant risks that must be managed. In order to promote quality and humanism in practice, the HAS has published its first guidelines for the proper use of generative AI in healthcare, intended for professionals, whether or not they are experts in the field.

Methods: The method used is based on a critical analysis of scientific literature, interviews with stakeholders, and a review by targeted stakeholders within the ecosystem.

Originality: This first guide on AI by the HAS provides the first framework in France for the use of generative AI in the healthcare sector. Particularly innovative, notably by its educational philosophy, it promote a didactic and pragmatic approach. It is divided.

Lessons learned and future implication: Every use of a generative AI system must be conscious, supervised, and reasoned. 4 guidelines are recommended: Learn: professionals familiarise themselves with how the generative AI system works and how to use it. Verify: professionals pay attention

Discussion: These recommendations are advisory. Thus, their implementation must be ensured. In order for these recommendations to be understandable and implementable by inexperienced users, they do not cover all issues associated with the use of AI. This guide will therefore need to be supplemented by further work. To this end, the HAS is developing additional recommendations to help healthcare institutions implement AI systems.

Conclusion: The HAS published the first guidelines for the use of generative AI in healthcare, with a rigorous scientific approach. This guide, the first of its kind in France, is designed to be pragmatic, grounded in reality and useful.

Corresponding author: Paul Valois, p.valois@has-sante.fr

ID 823- Artificial Intelligence: Defining the Ideal Tool by and for General Practitioners in France

Charles CAUET, Alexandre GUIGGI

District Of General Practice, Lille, France

Context: Artificial intelligence (AI) is rapidly transforming healthcare, with applications ranging from imaging and diagnostics to administrative support. However, its use in general practice remains limited, despite the central role of general practitioners (GPs) in the healthcare system. Understanding their expectations, needs, and concerns is crucial to designing tools that are both ethically sound and operationally useful in primary care.

Objectives: To explore the perceptions, expectations, and reservations of general practitioners in the XXX region regarding the use of artificial intelligence in clinical practice, in order to identify the features of an ideal, acceptable, and ethically integrated AI tool.

Methods: A qualitative study inspired by grounded theory was conducted between February and May 2024 among eleven community-based GPs (both established practitioners and locums). Semi-structured interviews were recorded, transcribed verbatim, anonymized, and analyzed through double coding and triangulation. Conceptual categories were developed to construct an explanatory model. The study followed COREQ

criteria and complied with all ethical and data-protection standards (RGPD).

Results: Participants expressed interest in AI tools that are simple, intuitive, and seamlessly integrated into existing medical software. AI was perceived as a potential support for clinical decision-making and a way to reduce administrative workload. Nevertheless, significant concerns persisted: data reliability, loss of professional autonomy, alteration of the doctor–patient relationship, and the risk of dehumanizing care. GPs emphasized the need for transparency of algorithms, human oversight, and direct involvement of physicians in the design and validation of these tools. AI should assist, not replace, the clinician's judgment.

Discussion: GPs view AI as a pragmatic opportunity to ease cognitive and administrative burdens, provided it respects the singularity of the clinical encounter. Their cautious optimism reflects both curiosity and ethical vigilance. Insufficient training and lack of exposure to AI technologies reinforce the need for participatory, co-design approaches involving frontline physicians.

Conclusion: Artificial intelligence in general practice should be designed by and for physicians. By incorporating user needs—simplicity, reliability, human supervision, and ethical transparency—AI can become a genuine tool for enhancing care quality without compromising the human relationship at the core of medicine.

Corresponding author: Charles Cauet, docteur.cauet@gmail.com

ID 129- AI-Enhanced Learning in General Practice: Opportunities, Challenges, and Future Directions

Alberto PARADA

Université Liège & Ssmg, Liège, Belgique

Context: The integration of artificial intelligence (AI) into medical education is profoundly reshaping pedagogical approaches in general practice. Advanced AI tools—from intelligent tutors to augmented reality systems—enable personalized learning, enhance performance analysis, and foster reflective practice. However, these innovations bring significant challenges related to training, ethics, and educational accountability. In an era where digital proficiency is essential, examining the role of AI in preparing future general practitioners is both urgent and foundational for the profession.

Objectives: This study aims to explore how AI enriches learning for medical students and practitioners in continuing education, identify the observed pedagogical benefits, and examine the ethical, curricular, and organizational challenges crucial to its sustainable implementation.

Methods: A narrative literature review (2020–2025) was conducted using PubMed, Scopus, and Consensus.app, focusing on the keywords "artificial intelligence," "medical education," "general practice," "simulation," and "ethics." Publications were analyzed through three lenses: educational innovation, curricular integration, and ethical considerations. Additionally, a thematic mapping of research trends was provided to highlight emerging domains in this field.

Results: Findings reveal that AI facilitates personalized learning trajectories (adaptive feedback, gap identification), enhances clinical simulation (via AR/VR), and supports data-driven clinical decision-making. Nonetheless, significant obstacles include insufficient AI-specific training, disparities in technological access, and risks related to algorithmic bias. AI-integrated educational approaches remain heterogeneous and lack standardization, although several pilot programs show promise for broader adoption.

Discussion: AI-augmented learning opens new horizons for general practice education, strengthening active pedagogy and practitioner reflexivity. Success requires robust ethical governance, comprehensive digital training embedded in curricula, and ongoing interdisciplinary dialogue between educators, computer scientists, and clinicians.

Conclusion: AI is a powerful driver for training the 21st-century general practitioner. Its successful integration must preserve humanistic aspects of care, promote equitable access, and support the development of critical and ethical competencies.

Corresponding author: Alberto Parada, alpadoc@gmail.com

ID 128- Empathy and Shared Vulnerability in the Age of Artificial Intelligence: Rethinking Care Ethics and the Humanization of Healthcare

Alberto PARADA

Université Liège & Ssmg, Liège, Belgique

Context: The deployment of artificial intelligence (AI) in healthcare is accelerating, simultaneously promising enhanced efficiency and raising profound questions regarding the human dimensions of care. Central issues emerge around empathy, shared vulnerability, and care ethics, as AI's capabilities challenge the irreplaceable quality of authentic human-to-human healthcare interactions.

Objectives: This review aims to critically examine how AI's incorporation into clinical practice influences core values of empathy, mutual vulnerability, and the ethical obligations of caregivers. The goal is to identify both the risks and opportunities presented by AI in upholding humanistic care, and to propose frameworks for ensuring technology remains a servant—not a substitute—for relationship-centered care.

Methods: A systematic literature review was conducted using the Consensus platform, Semantic Scholar, PubMed, and other databases. From roughly 980 initial publications, 50 highly relevant and recent peer-reviewed studies were selected. Thematic analysis focused on interdisciplinary perspectives—philosophy, ethics, sociology, and clinical evidence—exploring theoretical foundations and practical impacts of AI on empathy, care ethics, and vulnerability.

Results: Findings reveal a robust consensus: AI can streamline clinical workflows and free provider time but cannot genuinely replicate the depth, reciprocity, or transformative impact of human empathy. Simulated empathy from chatbots or care robots is usually perceived as superficial, risking decreased trust and relational authenticity. Conversely, AI—used judiciously—may reinforce relationship-based care by enabling professionals to concentrate on emotional and ethical engagement. Shared vulnerability, central to therapeutic alliance, remains largely unprogrammable and is best supported through direct human connection. Additional risks include potential exacerbation of inequities, clinical depersonalization, and ethical ambiguities in algorithmic decision-making.

Discussion: Empathy and vulnerability are not merely "soft skills" but pivotal determinants of patient outcomes, trust, and justice in healthcare. Care ethics, alongside alternative frameworks (Ubuntu, co-design), offers critical guidance. The literature strongly advocates for rigorous ethical oversight and sustained co-creation with clinicians, patients, and communities—to ensure technology complements rather than displaces care.

Conclusion: AI can support the humanization of care if developed and deployed within ethically robust, relationship-centered models. Ultimately, authentic empathy, recognition of vulnerability, and ethically guided practice must remain at the heart of healthcare, with AI as a tool enhancing—never replacing—the essence of care.

Cancer

ID 2158- Persistent hoarseness as an initial presentation of laryngeal cancer: A case report

Zarına AYIK, Konul ABDULLAYEVA, Vildan MEVSIM, Ozan ELIAÇIK

Department Of Family Medicine, Dokuz Eylul University Faculty Of Medicine, İzmir, Türkiye

Context: Laryngeal cancer is a common head and neck malignancy, strongly associated with tobacco use. Early symptoms may be subtle and are frequently first encountered in primary care. Persistent hoarseness lasting longer than three weeks—particularly in high-risk individuals—should prompt urgent evaluation. Family physicians play a critical role in recognizing red-flag symptoms and initiating timely referral.

Methods: A 62-year-old man presented to a family medicine clinic with progressive hoarseness lasting

one month. He also reported sore throat and unintentional weight loss of 7 kg over the same period. He was an active heavy smoker (approximately three packs per day) with a family history of lung cancer. He denied fever, night sweats, or dyspnea. Physical examination revealed marked dysphonia and a firm, non-tender left cervical lymph node measuring approximately 2 cm. Vital signs and basic measurements were within normal limits. Given the persistence of hoarseness, heavy tobacco exposure, weight loss, and cervical lymphadenopathy, a laryngeal malignancy was strongly suspected, and the patient was urgently referred to otorhinolaryngology. Three weeks later, the patient returned with hospital records. Fiberoptic and direct laryngoscopy revealed a suspicious laryngeal lesion, and biopsy confirmed squamous cell carcinoma of the larynx.

Originality: This case illustrates how a common symptom such as hoarseness can represent an underlying malignancy and emphasizes the pivotal gatekeeping role of primary care in early cancer detection.

Lessons learned and future implication: Persistent hoarseness beyond three weeks should always be evaluated carefully in primary care. Smoking history, weight loss, and cervical lymphadenopathy are critical red flags. Family physicians should maintain a low threshold for urgent referral, as ear

Discussion: Laryngeal cancer often presents with voice changes before advanced symptoms develop. In busy clinical settings, hoarseness may be misattributed to benign causes. This case demonstrates how systematic assessment and awareness of risk factors in primary care can prevent diagnostic delay.

Conclusion: Primary care physicians are essential in the early identification of laryngeal cancer. Careful history-taking, focused examination, and timely referral enable earlier diagnosis and improved patient outcomes. MeSH keywords (plain text): Laryngeal Neoplasms; Hoarseness; Primary Health Care; Smoking; Early Diagnosis; Squamous Cell Carcinoma

Corresponding author: Zarına Ayik, zarina.ibrahimova17@gmail.com

ID 1842- Lung cancer screening in smokers: Practices of general practitioners University Internship Supervisor in the Gers and Haute-Garonne departments

Audrey CHARRIE, Jean-Christophe POUTRAIN

Dumg Toulouse, Toulouse, France

Context: Lung cancer is the leading cause of cancer death in France. Tobacco is the risk factor. Scientific societies have advocated for lung cancer screening in smokers using low-dose chest CT scans. However, there are currently no official recommendations in France.

Objectives: To assess the practices of general practitioners who are also University Internship Supervisor in two french departments regarding lung cancer screening in smokers by low-dose chest CT scan.

Methods: It is an observational study conducted among general practitioners practicing in two french departments. The questionnaire, administered in « face to face », was based on a smoker patient previously selected by each practitioners from their patient base, according to the screening criteria defined by the French Society of Pulmonology.

Results: 60 general practitioners were recruited. 24 physicians prescribed a screening examination for the selected patient. 9 physicians still prescribed chest X-rays. 14 CT scans were nevertheless prescribed, 6 of which were low-dose scans, distributed equally between the physicians in the department n°1 (n = 3) and the department n°2 (n = 3). The lack of recommendations from the French National Authority for Health (HAS) remains the main obstacle for 62.9% of doctors. Access limitations to imaging facilities were cited by 40.7% of practitionners. Doctors who did not prescribe screening prioritized smoking cessation (83.3%).

Discussion: Our study highlights a heterogeneity of practices concerning the prescription of low-dose chest CT scans, without however revealing a statistically significant difference between two territories. Although the majority of the doctors surveyed are unfamiliar with low-dose chest CT scans, they nevertheless recognize their central role in lung cancer screening. Practitioners who do not

prescribe this screening prefer to focus their action on smoking cessation. The lack of clear and official recommendations appears to be the main obstacle to prescribing a low-dose chest CT scan. It would therefore be necessary to develop harmonized recommendations adapted to primary care.

Conclusion: The practices of general practitioners regarding lung cancer screening are heterogeneous. The majority do not perform low-dose chest CT scans. The lack of recommendations adapted to primary care is the main obstacle. It would therefore be necessary to develop harmonized recommendations.

ID 1283- Evaluation of a telephone intervention to improve colorectal cancer screening: assessment of participant's feedback

Zaouche YASMINE, Aujoulat PAUL

Spurbo, Brest, France

Context: Colorectal cancer screening is an effective way to reduce mortality and lower the cost of cancer care. Since 2024, the health insurance system has been providing general practitioners (GPs) with a list of their patients who are not up to date with their screening. Twenty-six medical students contacted the patients on their supervisors' lists by telephone to offer them screening.

Objectives: The aim of this study was to assess the medical student's feedback about the intervention.

Methods: It was a qualitative study conducted using an approach inspired by focus groups. The focus groups were led by three investigators throughout the intervention, at fifteen-day intervals, via videoconference to allow as many people as possible to participate. The videoconferences were recorded and transcribed. A thematic analysis was conducted between each meeting by the investigators and a sociologist.

Results: Four focus groups lasting an average of 1.5 hours were held. The phone calls were well received by patients, who felt that their local healthcare professionals were committed to their care. Many had not felt concerned by the screenings and changed their perspective following the call. The main reason for refusing colorectal cancer screening were anxiety, being asymptomatic or having a serious illness at the time. The medical students were satisfied to be participating in improving prevention in the region. One of the difficulties they encountered was the time-consuming nature of the intervention. They also noted inconsistencies in the participation of pharmacies in the delivery of kits, with some reported deviations such as billing for this service.

Discussion: This study showed that both patients and healthcare professionals welcomed this telephone intervention. The reasons for not being up to date for colorectal cancer screening identified are consistent with the findings of other studies.There are several limitations in this study particularly with regard to information bias.

Conclusion: This telephone intervention was well received and might increase the rate of colorectal cancer screening. This time-consuming work is difficult to replicate on the scale of a general practitioner within their own patient base. However, it can be replicated within the framework of coordinated care, for example with the help of medical assistants.

ID 932- Experiences of General Practitioners and Their Influence on Organized Cancer Screening in Patients with Severe Psychiatric Disorders: A Qualitative Study

Gaëlle RAGOT [(1)] , Nadine PELLEN [(2)], Aziliz LE GLAZ [(2)]

(1) Département Universitaire De Médecine Générale-Université De Bretagne Occidental, Brest, France
(2) Spurbo, Brest, France

Context: Schizophrenia and bipolar disorder are among the most severe psychiatric disorders (SPD) and affect 0.4% and 2% of the general population, respectively. The life expectancy of these patients is reduced by about 13 years compared to the rest of

the general population. Cancer is the second leading cause of death. However, they are less likely to benefit from organized cancer screening programs.

Objectives: The aim of this study was to understand general practitioners' perceptions and experiences of patients with TPS, as well as their effects on the implementation of organized screening programs.

Methods: Qualitative study inspired by grounded theory, conducted using semi-structured interviews with private general practitioners who treat patients with schizophrenia or bipolar disorder. The interviews were recorded, transcribed, and analyzed using an inductive thematic approach.

Results: Twenty-five interviews were conducted between October 2023 and February 2024. The doctors interviewed discussed the difficulties they encountered in establishing a solid therapeutic alliance with these patients. They were able to express their perceptions of STPs, as well as the specific obstacles associated with organized screening. Finally, the study highlighted several factors—such as the anticipation of refusal or the fear of complex care in the event of a positive screening result—that could lead to organized screening not being systematically offered to all patients and, in fact, result in a kind of selection of patients to be screened.

Discussion: The results of this study help explain the difficulties these patients encounter in accessing organized screening. However, these inequalities in access do not appear sufficient to account for the difference in cancer-related mortality compared with the general population. The findings highlight the need for personalized support for these patients. Evaluating the impact of a systematic preventive medical examination at the initiation of psychiatric care could be particularly relevant.

Conclusion: This study highlighted the perceptions that general practitioners had of patients with TPS, as well as the possible consequences of these perceptions on organized screening, which could lead to the selection of patients for screening.

ID 902- Clinical Nutrition Intervention for 75-Year-Old Female with Pancreatic Head Adenocarcinoma with Liver Metastasis: A Biomedical and Psychosocial Multidisciplinary Approach

Erica Tania DAVILLO

Department Of Family And Community Medicine Perpetual Help Medical Center Binan Laguna Philippines / Philippine Academy Of Family Physicians / Armed Forces Of The Philippines / Harvard Medical School / Philippine Medical Association / Philippine College Of Occupational Medicine, Valenzuela, Philippines

Context: Pancreatic cancer is major global health burden and the seventh leading cause of cancer mortality. It is complex malignancy shaped by genetic and environmental factors, with about 10% inherited in an autosomal dominant pattern. Adenocarcinoma is most common type, typically diagnosed around age 70, and often carries a poor prognosis due to late detection and aggressive progression. Treatment varies by tumor type, stage, and patient condition, ranging from surgery and chemotherapy to targeted therapy, immunotherapy, and palliative care. Nutritional compromise is frequent in advanced disease, complicating outcomes further.

Methods: This case describes 75-year-old immunocompromised female with pancreatic head adenocarcinoma, diffuse intraductal papillary mucinous neoplasm, and liver metastasis. Before medical and surgical interventions, comprehensive laboratory and imaging studies were performed. Nutritional screening guided tailored care plan that included total parenteral nutrition, enteral feeding, oral supplements, multivitamins, and trace elements, all adjusted to meet adequacy. Family members played central role in supporting adherence and strengthening psychosocial resilience.

Originality: The distinctiveness of this case lies in combining biomedical management with structured nutritional intervention and family-centered psychosocial support. While pancreatic adenocarcinoma cases are widely reported, the deliberate focus on correcting under

Lessons learned and future implication: This case underscores nutrition as a cornerstone of

readiness in complex malignancies and highlights family engagement in resilience building. Future directions include standardized nutrition protocols in cancer pathways, community-based nutrition educati

Discussion: The outcome illustrates that liberty in health is achieved when patients are empowered through adequate nutrition, equity is advanced when vulnerabilities are addressed through multidisciplinary care, and fraternity is embodied when families and healthcare providers collaborate. Success in cancer management is not solely technical but deeply dependent on holistic preparation.

Conclusion: This case exemplifies how biomedical, nutritional, and psychosocial integration can transform outcomes in advanced pancreatic cancer. It advocates liberty through patient empowerment, equity through comprehensive care, and fraternity through family and community solidarity, principles resonant with 30th WONCA Europe Conference theme and global primary care values.

ID 491- Effect of using a decision support tool for organized breast cancer screening by mammography in France

Sandrine HILD [(1)] , Delphine TEIGNE [(1)], Aurélie GAULTIER [(1)], Emmanuelle BATAILLE [(2)], Cédric RAT [(1)]

(1) Nantes Université, Nantes, France
(2) Cpam, Nantes, France

Context: The decision support tool XX (DST) was designed to assist French women in making shared decisions about whether or not to participate in organized breast cancer screening (OBCS) by mammography. The effects of this DST on women and their general practitioners (GPs) are to be evaluated.

Objectives: Main objective: To evaluate the effect of a trial incorporating the DST XX on the level of decision-making conflict regarding the choice of whether or not to participate among women invited to participate in OBCS. Secondary Objectives: To evaluate women's intention to participate in OBCS, the implementation of shared decision-making, their knowledge of OBCS, and their care pathways after receiving the invitation in OBCS.

Methods: Design: Randomized controlled trial with two arms conducted in a region of France (February–September 2025). Cluster randomization of 2767 GPs. Participants: 20000 women aged 50–74 invited to the OBCS in January 2025 by the National Health Insurance Fund and having a GP. Intervention: In the experimental arm, women and their GPs received a letter encouraging them to implement shared decision-making and a flyer presenting the DST. In the control arm, women and GPs continued screening as usual. Primary endpoint and secondary endpoints: Overall score on the Decision Conflict Scale (DCS - 16 items). Data collected via questionnaire 2 months after presentation of the DST. Scores on the Measures of Decision scale (1 item), Shared Decision Making Questionnaire (9 items), number of correct answers on the knowledge questionnaire (10 items), description of healthcare professionals seen by women. Statistical analysis: Comparison of scores between arms using mixed covariance analysis.

Results: 3104 questionnaires were received (out of 1522 needed to conclude that there was a difference). The results, which are currently being analyzed, will be presented at the conference. A decrease in decision conflict is expected in the experimental group, with no change in intention to participate.

Discussion: This study will evaluate the effect of DST on a large scale in a routine care setting.

Conclusion: This DST, made available to women and all professionals in the OBCS, would promote interaction between women and GPs, could improve women's adherence to screening, and could limit health inequalities.

ID 360- Participation in cervical cancer screening among eligible LGBTIA+ individuals in the XXX region : a cross-sectional quantitative study.

Juliette NICOLAS [(1)] , Marjolaine CAZAILLET [(1)], Irène MÉRIAUX [(1)], Maeva JEGO-SABLIER [(2)]

(1) Département Universitaire De Médecine Générale, Smpm, Aix-Marseille Université, Marseille, France
(2) Département Universitaire De Médecine Générale, Smpm, Aix-Marseille Université + Ceress, Aix-Marseille Université, Marseille, France

Context: Cervical cancer remains a major public health issue in XXX, with a significant development of organized screening programs in recent years. However, lesbian and bisexual women, transgender men, and non-binary individuals represent a population often overlooked by prevention policies. Several studies report numerous forms of discrimination leading to lower access to healthcare.

Objectives: This study aims to investigate the participation rate in cervical cancer screening among eligible LGBTIA+ individuals in the XXX region and to identify the factors influencing screening participation.

Methods: An anonymous questionnaire was distributed online from March to July 2025 through LGBTIA+ associations. Lesbian and bisexual women, transgender men, and non-binary individuals aged 25 to 65 years and residing in the XXX region were included. The primary outcome was being up-to-date with cervical cancer screening. A univariate analysis was then conducted to identify the factors influencing screening participation.

Results: A total of 226 participants were included. The screening participation rate was 65.0%. Factors significantly associated with a higher screening rate were age, department of residence, having a general practitioner and discussing sexual orientation with the healthcare provider performing the cervical smear. Among the main barriers reported were negative experiences during gynecological consultations (29.1%) and the lack of screening proposal from healthcare provider (16.5%).

Discussion: This study is one of the few that includes transgender and non-binary individuals. However, the recruitment by LGBTIA+ associations introduces a selection bias, favoring younger, urban, and more informed participants, which may overestimate the screening rate. Nevertheless, the rate is similar to other XXX studies, such as XXX, which found a screening rate of 64,7% and also highlights the importance of the general practitioner and discussing sexual orientation in encouraging participation in screening.

Conclusion: The disparities in cervical cancer screening among LGBTIA+ individuals highlighted in this study emphasize the need for more inclusive communication and improved training for healthcare providers to enhance the therapeutic alliance. The lack of data and epidemiological studies hinders the improvements of LGBTIA+ individuals healthcare. It is therefore essential to continue this work with large-scale quantitative studies, on STIs in general, to develop truly inclusive and equitable prevention policies.

(3) Centre Hospitalier De Voiron, Voirons, France
(4) Has, Paris, France
(5) Esp De Mongiscard, Baziege, France

Context: Chronic pain affects 23 million people in France and is one of the leading reasons for consultations with general practitioners (GPs). Despite having over 250 chronic pain centers nationwide, these facilities are overwhelmed, with waiting times of up to eight months. In response, the French National Authority for Health (HAS) proposed a “Healthcare Pathway for People with Chronic Pain” in 2023. However, no institutional resources are available to implement this pathway in primary care.

Methods: A chronic pain healthcare pathway was implemented within a Primary Care Team in a specific region. Developed collaboratively by various healthcare professionals, the pathway involved a

self-assessment of pain by a paramedic, followed by a consultation with the GP to review the assessment and set treatment goals. A multi-professional meeting, including a pain specialist, formulated a treatment plan. Six months later, an assessment was conducted. Over two years, 30 chronic pain patients were managed locally, with only two referred to hospital-based teams. This process involved a one-hour paramedic consultation, a GP consultation, and a multi-disciplinary consultation for each patient, requiring financial resources to cover associated costs.

Originality: To our knowledge, this is the first French study to describe the implementation of a multi-disciplinary chronic pain pathway in primary care.

Lessons learned and future implication: Successful implementation of a primary care pathway depends on clearly defining each professional's role. Coordination and continuous patient monitoring are crucial for effective care, allowing caregivers to focus on quality care. Adequate human and finan

Discussion: The integration of a pathway in primary care, supported by tele-expertise during multi-disciplinary meetings, ensures efficient chronic pain management in the community. However, it requires a GP involved in pain management and a dedicated coordinator for vigilant patient monitoring. Financial support is essential for the pathway's long-term sustainability.

Conclusion: This experience demonstrates the feasibility of a primary care pain pathway. However, its successful implementation requires adequate human and financial resources, which are not currently planned by public health authorities.

ID 1727- Upper extremity activity levels and pain in older adults: an observational study in assisted living facilities

Fanny CHARPENTIER [(1)] , Emilie LEBLONG [(2)], Aurélie TOMEZZOLI [(3)]

(1) Département De Médecine Générale De La Faculté De Médecine, Campus Santé, Université De Rennes, 35043 Rennes Cedex, Rennes, France
(2) Service De Mpr Neurologique, Unité De Médecine Du Handicap, Lab St Hélier, Fondation St Hélier, Rennes, France, Rennes, France
(3) Société De Formation Thérapeutique Du Généraliste (sftg) Recherche, Paris, France ; Univ Rennes, Inria, Cnrs, Irisa-Umr 6074, 35000, Rennes, France, Rennes, France

Context: Upper limb musculoskeletal disorders have been extensively studied in the workplace. In older adults, their prevalence and consequences, in terms of associated activity limitations and pain, remain largely unexplored, except in a few studies focusing on shoulder pain.

Objectives: To quantify the prevalence of activity limitations and pain associated with upper limb dysfunction, among independent older adults living in assisted living facilities.

Methods: A cross-sectional, declarative study is ongoing in three assisted living facilities in XXX, XXX. At least 162 residents aged 75 years or older will complete a self-administered questionnaire. Exclusion criteria included cognitive disorders hindering questionnaire comprehension or being under guardianship or conservatorship. The Disabilities of the Arm, Shoulder and Hand (DASH) score and sociodemographic characteristics were described using R. The study was approved by the Ethics Committee of XXX (No. XXX).

Results: Among the 78 residents (63 women) currently included, the average DASH score was 28.5 ± 22.9 (0 = no disability; 100 = most severe disability). Upper extremity pain was reported by 64% of residents; 86% of them experienced shoulder pain, 44% hand pain, 26% wrist pain, and 12% elbow pain. Additionally, 26% of the residents who experienced pain had not informed their general practitioner of this issue.

Discussion: In these preliminary results, DASH scores and pain prevalence were elevated, with substantial underreporting to the general practitioner. This may reflect specific resident characteristics, including recruitment location and a higher inclusion age threshold than in previous studies. High interindividual variability in DASH

scores was also observed. These findings highlight the potential value of systematic screening in primary care to limit the risk of functional decline, but should be interpreted cautiously given their preliminary nature.

Conclusion: Upper limb activity level restrictions and pain were common in the study population. The full dataset will be obtained in February 2026. Descriptive statistics will be updated, and associations between residents' characteristics and outcomes will be explored to assess the generalizability of the results to a broader population of older adults.

ID 1415- Challenges in managing early-to-moderate chronic kidney disease in primary care: a systematic review in high-income countries

Killian L'HELGOUARC'H [(1)] , Olivier MORANNE [(2)], Béatrice LOGNOS [(2)], Elodie MILLION [(2)], Agnès OUDE-ENGBERINK [(2)]

(1) Department Of General Medicine, Faculty Of Medicine, University Of Montpellier, Montpellier, Occitanie, France., Montpellier, France
(2) Desbrest Institute Of Epidemiology And Public Health. Umr Ua1368 Inserm-University Of Montpellier, Montpellier, Occitanie, France, Montpellier, France

Context: Early identification and management of chronic kidney disease (CKD) - affecting 850 million people worldwide - are essential to slow progression and reduce complications. Yet, underdiagnosis remains common despite clear screening tools (creatinine, albuminuria). This reflects persistent gaps in care coordination between primary and specialist teams, undermining timely intervention and optimal patient outcomes.

Objectives: This systematic review aimed to describe how early-to-moderate CKD is identified and managed in high-income countries, and to assess initiatives designed to improve care.

Methods: Outpatients with early-to-moderate CKD (stages 1–3b) and healthcare professionals involved in their care. We searched, MEDLINE, Embase, Cochrane Library, Knowledge Translation+, and PDQ-Evidence for descriptive, qualitative, mixed-methods, and interventional studies focusing on early-to-moderate CKD management in high-income countrie Data were extracted using JBI tools. We conducted a convergent integrated synthesis.

Results: Ninety studies were included (46 descriptive, 23 qualitative/mixed-methods, 21 interventional), involving 33.4 million patients and 3,180 professionals. Primary care management of early-to-moderate CKD was consistently suboptimal, with limited guideline knowledge leading to inadequate albuminuria screening, poor coding, insufficient follow-up, and medication errors. Coordination with nephrologists was inconsistent, referral criteria were variably applied, and many eligible patients were not referred. Patients frequently lacked awareness of their diagnosis and encountered barriers to self-management. Interventional studies showed modest effects: educational programs alone rarely improved screening or prescribing; screening campaigns increased testing but had uncertain cost-effectiveness; and digital decision-support tools improved specific processes but yielded inconsistent clinical benefits. The most effective strategies were multimodal interventions, combining decision-support systems, practice facilitators or trained nurses, structured monitoring, and patient education, which improved CKD identification, albuminuria testing, blood pressure control, and medication safety.

Discussion: This review reveals a gap between guidelines and real-world practice in CKD management in primary care, marked by challenges in screening, diagnosis and coordination with nephrologists. Multimodal interventions (digital tools, interprofessional teams) improve guideline adherence, though effectiveness varies. Heterogeneity in study designs and outcomes precluded meta-analysis.

Conclusion: Early-to-moderate CKD care remains suboptimal. Improving outcomes requires integrated, multimodal interventions supporting primary care teams, enhancing coordination with nephrology, and empowering patients.

ID 1372- Optimizing Dyslipidemia Management in Primary Care Following the 2025 ESC/EAS Focused Guideline Update

Majdi LAATAR

Istanbul Medipol University, Istanbul, Türkiye

Context: Dyslipidemia remains a main risk among modifiable ones for atherosclerotic cardiovascular disease. The updated 2025 focused on the ESC/EAS Guidelines highlights new evidence and recommendations that impact primary prevention, pharmacotherapy, and risk assessment approaches which offers clear updates for family physicians and especially the way they handle patient`s treatment.

Objectives: To summarize changes in practical updates in dyslipidemia management for general practitioners, highlighting recent methods of assessing cardiovascular risk, pharmacological strategies, while integrating doable steps into regular clinic visits.

Methods: We conducted a narrative synthesis based on the 2025 ESC/EAS updated guidelines, along with newer research and recent publications on implementation in general practice with tools meant to facilitate its do ability. The examination highlighted how strong the underlying evidence was, while also pointing out actual factors that matter for doctors working in primary care.

Results: The 2025 ESC/EAS guidelines offer general practitioners a significant shift in approaches; especially while evaluating cardiovascular risks, also a variety of treating options and strategies for dyslipidemia. Family physicians should adopt tools like SCORE2, including risk modifiers, and consider non statin therapies if there is indication. Applying these recommendations has shown that is not only able to reduce cardiovascular risk but also may ensure equitable preventive care in the local primary care settings.

Discussion: Updated guidelines significantly affect the way cardiovascular disease`s prevention is managed in primary care clinics; since updated risk assessment strategies must now fit with wider choice of treatment using the new guidelines. Moving forward, a challenge will be to provide fair availability of advanced medications while also using tests that adjust risk assessments in special cases.

Conclusion: The 2025 ESC/EAS guidelines offer general practitioners a significant shift in approaches; especially while evaluating cardiovascular risks, also a variety of treating options and strategies for dyslipidemia. Family physicians should adopt tools like SCORE2, including risk modifiers, and consider non statin therapies if there is indication. Applying these recommendations has shown that is not only able to reduce cardiovascular risk but also may ensure equitable preventive care in the local primary care settings.

ID 1315- Performance of the HEAR score in excluding acute coronary syndrome

Emna AYACHI, Yessmine WALHA, Wiem DEMNI, Eya OUERGHI, Feten SEBAI, Lina HAMDI, Nourelhouda NOUIRA

Mongi Slim University Hospital, Tunis, Tunisie

Context: Chest pain is among the most frequent complaints in patients presenting to the emergency department, and acute coronary syndrome (ACS) remains a diagnostic challenge for clinicians. The HEAR score is a clinical tool developed to identify patients at low risk for ACS.

Objectives: This study aimed to evaluate the performance of the HEAR score in excluding ACS and predicting major adverse cardiovascular events (MACE) within six weeks.

Methods: We conducted a prospective, descriptive, and analytical study at the emergency department of Mongi Slim Hospital between January 1, 2022, and September 30, 2023. Patients presenting with acute non-traumatic chest pain were included. The HEAR score was calculated for each patient, and a follow-up telephone contact was performed after six weeks to identify any MACE.

Results: A total of 277 patients were enrolled, with a mean age of 63 ± 16.5 years and a male-to-female ratio of 1.9.Based on the HEAR score,38.3% were

classified as low risk,49.1% as intermediate risk, and 12.6% as high risk. ACS was diagnosed in 27.8% of patients, with only 0.9% in the low-risk group. The HEAR score showed an area under the curve (AUC) of 0.85 ($p < 0.01$;95% CI [0.80–0.89]). A threshold of <4 had a sensitivity of 98.7%,specificity of 52.8%, positive predictive value (PPV) of 45.6%,negative predictive value (NPV) of 98.2%,and likelihood ratio (LR-) of 0.02 for excluding ACS.HEAR score <4 was predictive of absence of ACS in univariate analysis ($p < 0.01$; OR = 1.78; 95% CI [1.56–2.04]). Within six weeks,21%of patients experienced MACE.The AUC for predicting MACE was 0.74 ($p < 0.01$; 95% CI [0.68–0.80]), with a HEAR cutoff <3 showing sensitivity 98.2%,specificity 33.6%,PPV 27.9%,NPV 98.7%, and LR- 0.05.HEAR score <4 predicted the absence of MACE ($p < 0.01$; OR = 5; 95% CI [4.9–7.2]).

Discussion: Previous studies support these findings.Mirfazaelian et al.demonstrated that HEAR score cutoffs<2,<3,and<4 in the emergency department had high sensitivity and NPV,with<2 being sufficient for early discharge.Similarly,Šljivo et al.reported high sensitivity and NPV for 30-day MACE in 2024.

Conclusion: The HEAR score is a simple and reliable clinical tool to rule out ACS in low-risk patients,aiding rapid triage and decision-making in the emergency setting.

Corresponding author: Yessmine Walha, yessmine.walha@fmt.utm.tn

ID 960- Exercise prescription for adults with chronic kidney disease in primary care: a narrative review

Julia PANZAN, Gabriela ROGICK, Naila OLIVEIRA, Marcio MELO, Andre FREITAS, Brenno CAMPOS

Faculdade São Leopoldo Mandic Araras, Araras, Brésil

Context: Chronic kidney disease (CKD) is associated with accelerated functional decline, elevated cardiovascular risk, and increased mortality. Evidence suggests that structured physical activity can improve functional capacity, blood pressure control, and metabolic health in CKD populations; however, exercise prescription tailored for primary care delivery remains underdeveloped.

Objectives: To synthesize current evidence on exercise interventions applicable to adults with CKD in primary care settings and to identify practical components for safe, feasible, and effective exercise prescription.

Methods: This integrative review followed a systematic search in PubMed using MeSH descriptors (“Chronic Kidney Disease,” “Exercise,” “Primary Health Care”) combined with Title/Abstract terms. Inclusion criteria encompassed adults (≥18 years) with CKD undergoing exercise interventions feasible for primary care, including randomized trials, observational studies, and protocols. Exclusion criteria comprised pediatric populations, inadequate kidney disease characterization, case reports, editorials, and studies conducted exclusively in tertiary settings without primary care transferability. Ten studies were identified; four met eligibility criteria after independent screening. Data were extracted using standardized forms addressing design, population characteristics, exercise modality, feasibility, safety, and outcomes.

Results: Included studies comprised one randomized controlled trial, two observational cohorts, and one protocol, representing diverse CKD populations and exercise modalities. A 12-month supervised aerobic-resistance program in stage G3b–4 CKD significantly improved six-minute walk distance and mobility without exercise-related adverse events. Observational data from kidney transplant recipients showed higher physical activity levels were independently associated with fewer cardiovascular risk factors. Isometric exercise protocols demonstrated high feasibility (59% attendance) and clinically meaningful systolic blood pressure reductions in community settings. One population-based protocol incorporated multi-component primary care, including structured physical activity assessment, to prevent frailty progression.

Discussion: Evidence demonstrates that structured exercise—particularly combined aerobic-resistance training and simplified isometric protocols—is feasible, safe, and beneficial across CKD stages. Protocol heterogeneity and limited representation of early CKD highlight the need for pragmatic, primary-care-based trials with standardized measures.

Conclusion: Exercise prescription for adults with CKD is a safe, feasible, and clinically meaningful intervention. Primary care represents an effective platform for implementing low-complexity, evidence-based exercise programs that preserve functional capacity and mitigate cardiovascular risk.

Corresponding author: Julia Panzan, juliadepaulapanzan@gmail.com

ID 642- French primary care management of celiac disease has been steadily increasing over the past 10 years

Kaheina AIZEL [(1)] , Yannick GIRARDEAU [(2)], Georgia MALAMUT [(3)]

(1) Université Paris Cité, Paris, France
(2) Department Of Clinical Investigation And Clinical Epidemiology, Hôpital Européen Georges Pompidou, Ap-Hp– Université Paris Cité, Paris, France
(3) Department Of Gastroenterology, Hôpital Cochin, Ap-Hp – Université Paris Cité, Paris, France

Context: While celiac disease (CD) prevalence is common (≈1%), most adult cases remain undiagnosed. In adults, diagnosis currently requires duodenal biopsies. In children, however, high anti-transglutaminase antibody (tTG) levels (≥10× normal) plus positive anti-endomysial antibodies (EMA) are sufficient for diagnosis, avoiding biopsies as per ESPGHAN guidelines. CD management relies on a strict lifelong gluten-free diet, requiring regular clinical and serological follow-up, including repeated serological testing. However, primary care screening and follow-up practices for CD in France remain unknown.

Objectives: To assess national and regional trends in CD management in primary care through the prescription of specific celiac antibodies.

Methods: Using OPENBio data from the French national health insurance, we analysed prescriptions of anti-transglutaminase and anti-endomysial antibodies by general practitioners in metropolitan France (2014–2024). We included IgA and IgG serological tests for both antibodies. Overseas regions were excluded due to incomplete data. The primary endpoint was the national prescription rate (per 10,000 inhabitants/year). Secondary endpoints were regional rates to compare activity and identify high/low prescription areas. Statistical analysis included trend analysis via linear regression (2014–2024), Student's t-test, and two-way ANOVA (region/year).

Results: We found a significant increase in CD serology prescriptions, from 17.3 per 10,000 inhabitants in 2014 to 36.5 in 2024, representing an average annual growth of 7.7%. A slight drop occurred during the 2020 COVID-19 crisis (4.2 fewer prescriptions/10,000, ~16% decrease). Among the tests prescribed, 84% were anti-tTG and 16% anti-EMA Regional disparities were observed, with a prescription gradient increasing from Southeast to Northwest. For example, Provence-Alpes-Côte d'Azur had 2.3 times more prescriptions than Pays de la Loire, consistently over 10 years.

Discussion: Prescriptions of anti-transglutaminase and anti-endomysial antibodies in France have increased by ~7.7% annually over the past decade. This may partly reflect the 2012 ESPGHAN guideline allowing paediatric diagnosis based solely on serology. The regional gradient (higher in the Southeast) could be linked to proximity to Italy, where CD screening is a public health priority.

Conclusion: Future work will examine the impact of primary care antibody prescriptions on confirmed CD diagnoses using hospital data (PMSI). Keywords: Celiac Disease, Serologic Tests, Antibodies, Primary Healthcare

Covid and respiratory diseases

ID 2280- Activity related to long COVID in French general practice in 2023-2024

Eugénie PETREQUIN [(1)] , Olivier STEICHEN [(2)], Brigitte RANQUE [(3)], Louise ROSSIGNOL [(3)], Xavier GOCKO [(4)], Henri PARTOUCHE [(5)], Olivier ROBINEAU [(6)], Clément TURBELIN [(1)], Thierry BLANCHON [(1)], Marion DEBIN [(1)]

(1) Sorbonne, Paris, France
(2) Sorbonne, Aphp, Paris, France
(3) Paris Cité, Aphp, Paris, France
(4) Jean Monnet, Saint-Etienne, France
(5) Paris Cité, Paris, France
(6) Hôpital De Tourcoing, Tourcoing, France

Context: Long COVID has emerged as a significant public health concern. General practitioners (GPs) are the first point of contact for managing these

patients, but data on the related workload remains limited.

Objectives: This study aimed to assess the impact of long COVID on GPs' workload in France over one year and to identify factors associated with higher consultation volumes.

Methods: We conducted a longitudinal prospective study from June 2023 to May 2024 involving 141 GPs recruited through the French Sentinel network and the National College of General Practitioners. Monthly, GPs reported the number of distinct long COVID patients seen (WHO criteria); the same patient could be reported across multiple months. Multivariate logistic regression analyses identified factors associated with cumulative monthly patients reports at or above the sample mean.

Results: GPs reported a mean of 0.72 distinct long COVID patients per month (SD = 1.39), corresponding to a cumulative total of nine over 12 months (used as threshold). Most GPs (77.3%) reported below the threshold; 22.7% at or above. GPs' self-reported overall workload (three levels) was significantly associated with reporting at or above threshold. Compared with GPs reporting moderate workload, those with strong and very strong self-reported workloads had ORs of 1.18 (95% CI [0.29–5.34]) and 5.65 (95% CI [1.31–30.2], p = 0.017), respectively. GPs comfortable managing anxiety/depressive were less likely to report at or above threshold (OR = 0.18, 95% CI [0.03-0.88], p = 0.033). Higher patient volumes trended toward access to dedicated resources (OR = 3.03, 95% CI [1.00-10.2], p = 0.051).

Discussion: The low observed workload contrasts with international (30–51%) and French (4–8%), prevalence estimates, potentially reflecting definition or methodological differences between studies. The negative association between managing anxiety/depression comfortably and the number of long COVID cases is likely explained by GPs attributing overlapping symptoms to anxiety or depression rather than retaining a long COVID diagnosis.

Conclusion: Long COVID represents a low workload for French GPs. The negative association between confidence in managing anxiety/depression and long COVID patient volumes warrants further investigation to understand how GPs conceptualize and diagnose this complex condition.

ID 2162- Fixed Drug Eruption After Nirmatrelvir/Ritonavir: A Case Report

Aleksander STEPANOVIC

Ozg, Gosposvetska 9, Kranj, Slovénie

Context: Fixed drug eruption (FDE) is a type IV hypersensitivity reaction characterised by well-demarcated erythematous macules or plaques that recur at the same site after re-exposure to the causative drug. It accounts for 2.5–22% of cutaneous adverse drug reactions, with rising incidence due to increased drug use and awareness. FDE affects all ages and both sexes, most commonly adults aged 20–40 years. Typical triggers include antibiotics, non-steroidal anti-inflammatory drugs, and paracetamol. Lesions usually appear within 48–72 hours after exposure and often resolve with residual hyperpigmentation. Diagnosis is mainly clinical and may be supported by skin biopsy. Management includes discontinuation of the offending drug and topical corticosteroids.

Methods: A 55-year-old overweight man with type 2 diabetes developed malaise, myalgia, respiratory symptoms, and fever. He tested positive for COVID-19 and was treated with nirmatrelvir 300 mg plus ritonavir 100 mg twice daily for five days, with rapid improvement. Twelve days after starting treatment, he noticed a ring-shaped erythema in the right groin.

Originality: This is the first reported case of FDE associated with nirmatrelvir/ritonavir.

Lessons learned and future implication: Suspected Lyme disease was treated with azithromycin without effect, and the lesion enlarged and darkened. Antifungal therapy was also ineffective. Laboratory tests were normal and there was no systemic involvement. Dermatological assessment suggested FDE

Discussion: Nirmatrelvir/ritonavir is widely used in patients at risk of severe COVID-19. Reported adverse effects are mostly mild, while cutaneous reactions are uncommon. Re-exposure to the causative drug should be avoided, as recurrence may be more severe and progress to generalised bullous FDE.

Conclusion: As use of this therapy continues, awareness of possible cutaneous adverse reactions is essential for early recognition and prevention of serious complications.

Corresponding author: Aleksander Stepanovic, aleksander.stepanovic1@guest.arnes.si

ID 1625- Do RAAS inhibitors protect from hospitalization amongst primary care patients with proven SARS-Cov-2 infection in the French region of Yvelines?

Jules RICHARD, Caroline HUAS, Mathilde FRANCOIS, Florence PINSARD-LAVENTURE, Pascal CLERC

Uvsq, Versailles, France

Context: The COVID-19 pandemic significantly disrupted primary care organization, prompting innovative responses such as the establishment of numerous ambulatory COVID-19 consultation centers in the Yvelines department, France. These centers enabled real-time epidemiological work by centralizing clinical data, addressing the increasing need for primary care data to inform healthcare improvements. Among the scientific debates sparked by the pandemic, the role of angiotensin-converting enzyme inhibitors (ACEIs) and angiotensin II receptor blockers (ARBs)—common first-line antihypertensive treatments—in COVID-19 progression has been particularly contentious. Since the ACE2 receptor serves as the entry point for SARS-CoV-2, and its expression is altered by these medications, their potential impact on disease severity has been closely examined.

Objectives: This study aimed to assess whether exposure to ACEIs or ARBs in outpatient COVID-19 care in Trappes (Yvelines, France) influenced the risk of developing severe disease requiring hospitalization.

Methods: The research included 296 adult patients with positive PCR tests who consulted at the Trappes COVID-19 center. Data were collected via physician-completed questionnaires and medical record reviews. Univariate and multivariate logistic analyses were performed to evaluate the risk of hospital referral

Results: 47 patients were treated with renin-angiotensin-aldosterone system (RAAS) inhibitors. These patients were older and had more comorbidities. Statistical analysis revealed a significant association between RAAS inhibitor use and increased risk of hospitalization (OR = 1.17 [1.03–1.34]).

Discussion: While this study highlights long-term ACEI/ARB treatment as a risk marker for hospitalization among COVID-19 patients, the finding may reflect underlying comorbidities or local socio-economic factors rather than a direct drug effect. Previous meta-analyses have not confirmed a harmful impact of these treatments on COVID-19 outcomes. Limitations include potential biases from questionnaire-based data collection and lack of systematic follow-up. Conducted during the first two pandemic waves, the results may not apply to current, less virulent SARS-CoV-2 variants

Conclusion: This research underscores the value of regional primary care databases for identifying population-specific risk factors. Routine data collection could enable general practitioners to better identify at-risk patients and tailor their care, potentially adjusting treatments at the local or regional level as needed.

Corresponding author: Jules Richard, jules.richard@uvsq.fr

ID 1137- Overprescribing in acute respiratory disease, increasing antibiotic resistance: Practice-Based Reflection on the benefits of Point of Care Ultrasound

Pascual DAZA-RAMIREZ

Gp Trainer, Nhs England, St Austell, Cornwall, Royaume-Uni

Context: The overprescribing of antibiotics in acute lung disease is considered a global health problem because it is a major driver of antimicrobial resistance (AMR), which leads to increased morbidity, mortality, and healthcare costs worldwide. Lung ultrasound(LUS) demonstrates high diagnostic accuracy in the assessment of patients with acute respiratory disease. For pneumonia, pooled meta-analyses report sensitivity ranging from 88% to 95% and specificity from 94% to 98% when compared to chest radiography or CT. In the emergency setting, lung ultrasound outperforms chest radiography in sensitivity while maintaining similar specificity. A doctor can become competent at performing LUS assessment for the diagnosis of pneumonia after a focused training program consisting of 2 to 5 hours of didactic and hands-on instruction, followed by 20–25 supervised examinations.

Methods: Review of current published literature

Originality: Most systematic reviews focus on either the diagnostic performance of lung ultrasound, the epidemiology and drivers of antibiotic overprescribing in acute respiratory disease, or the feasibility and training requirements for point-of-care ultrasound in ge

Lessons learned and future implication: Several key lessons emerge First, lung ultrasound is a highly accurate, rapid, and noninvasive diagnostic tool Second, overprescribing antibiotics for acute lung disease is driven by diagnostic uncertainty and patient expectations, especially in primary

Discussion: Lung ultrasound reduces diagnostic uncertainty. The diagnostic accuracy is achievable by family physicians after focused, practical training, with competence improving further with ongoing practice and feedback. There is a need to train family doctors in the use of LUS. This is likely to have a significant positive impact in reducing inappropriate use of antibiotic prescribing which in turn will slow down antibiotic resistance. Healthcare systems would benefit from potential cost savings and improved equity. However this would require investment in education, equipment, and quality assurance infrastructure.

Conclusion: The successful implementation of LUS in primary care requires tailored, longitudinal training programs, ongoing mentorship, and system-level support to overcome barriers such as equipment access, supervision, and workflow integration. When these are addressed, family doctors report increased confidence, skill, and frequency of LUS use, with positive impact on clinical decision-making and resource utilization.

ID 1111- What healthcare utilization for long Covid ?

Stéphane BOUXOM [(1)] , Hayatte SABI [(1)], Sabrina EL MAHI [(1)], Béatrice TROMBERT-PAVIOT [(2)], Pascal CATHÉBRAS [(3)], Xavier GOCKO [(1)]

(1) Département De Médecine Générale, Saint Etienne, France
(2) Service De Santé Publique-Chu Saint Etienne, Saint Etienne, France
(3) Service De Médecine Interne-Chu Saint Etienne, Saint Etienne, France

Context: The global cumulative incidence of Post-COVID-19 condition, or long COVID, is estimated at 409 million individuals, with a persistent prevalence ranging between 6% and 7% of adults. Its symptoms, numerous and unspecific, undoubtedly impact the quality of life of those affected. Many factors have been associated with poorer recovery (e.g. smoking, obesity). Factors associated with a better quality of life have been little studied.

Objectives: To identify healthcare utilization profiles associated with a better quality of life among members of the "Tous Partenaires COVID" a large audience national association of patients with long COVID.

Methods: A self-administered online questionnaire was sent to the members of the association. The questionnaire included the criteria of the WHO definition of long COVID. It focused on the current health status felt by the participants using the standardized EQ-5D-5L scale, and listed a panel of

interventions (e.g. rehabilitation program), social support (e.g. support from relatives) and life changes (e.g. workstation adjustment) that were perceived (or not) as helpful by the subjects interviewed. Comorbidities before COVID-19, the period of onset of the acute infection and the notion of vaccination against SARS-CoV-2 were also recorded.

Results: Four profiles of healthcare utilization were identified among patients with long COVID: complex care involving several specialists and rehabilitation, specialized medical care without rehabilitation, follow-up by general practitioner alone, and minimal use of the conventional medical system. Patients without conventional medical follow-up and those followed only by a general practitioner reported a higher perceived quality of life. Conversely, patients receiving more complex care displayed lower quality of life scores, suggesting that sophisticated medical care does not always correlate with perceived health improvement.

Discussion: These paradoxical results could be due to a causal bias, with the most disabled and distressed subjects receiving complex care and the least symptomatic subjects receiving lighter care. But they also raise questions about the potentially iatrogenic impact of healthcare system utilization in the context of “medically unexplained” somatic symptoms, which may contribute to their reinforcement and persistence.

Conclusion: Access to ultra-specialized healthcare services may not be correlated with a better quality of life.

ID 50- Cognitive impairment after SARS-CoV2 pandemic in primary care

Ana Maria GARCIA-RODRIGUEZ [(1)] , Miguel Jose SANCHEZ-VELASCO [(2)], Cristina FRANCO-GIL [(1)], Rebeca VEGA-GUTIERREZ [(1)], Ines VACA-FERNANDEZ [(1)], Lucia GARCIA-APARICIO [(1)], Irene GARCIA-MARTIN [(1)], Rebeca HERNANDEZ-ROMAN [(1)]

(1) Cs Plaza Del Ejercito Gerencia Atencion Primaria Valladolid Oeste, Valladolid, Espagne
(2) Gerencia Regional De Salud, Castilla Y León, Valladolid, Espagne

Context: The SARS-CoV-2 pandemic has drawn attention to its potential neurocognitive sequelae, with evidence suggesting post-infectious impairments in memory, attention, and executive functions. However, community-based data in Primary Care remain limited. This study explores whether a history of COVID-19 is associated with cognitive decline and which sociodemographic factors influence cognitive performance.

Objectives: To identify cognitive differences between patients with and without prior COVID-19 infection, evaluate the influence of age, sex, and educational level, and determine which cognitive domains are most affected in the post-pandemic period.

Methods: A cross-sectional observational study was conducted during 2024–2025 at XXXXXXXXXXXX. The self-administered SAGE questionnaire was applied to 380 patients aged ≥14 years. Sociodemographic variables, history of COVID-19, hospitalization, and ICU stay were analyzed. A SAGE score <17 points was considered indicative of cognitive impairment.

Results: The mean SAGE score was 18.4 ± 3.9. The overall prevalence of cognitive impairment (SAGE < 17) was 22.9%. There was no significant association between prior COVID-19 infection and global cognitive impairment ($p = 0.409$). Lower scores were strongly associated with older age (≥60 years; $p<0.001$) and low educational level ($p<0.001$), while sex showed no significant effect. The “money” subtest, which assesses simple calculations and functional reasoning, showed a modest but significant difference ($p = 0.021$).

Discussion: These findings suggest that age and education remain the strongest determinants of cognitive performance, while the impact of COVID-19 infection itself appears minimal in community-dwelling individuals. The slight difference in financial-calculation performance may reflect specific-domain cognitive reserve rather than a

direct viral effect. These results are consistent with large community cohorts reporting limited long-term cognitive effects after mild COVID-19.

Conclusion: In this Primary Care sample, no direct cognitive impact of prior SARS-CoV-2 infection was found. Older age and lower education were confirmed as key predictors of cognitive decline. The SAGE test proved useful and sensitive for detecting subtle cognitive changes and is recommended for routine screening in vulnerable populations.

Deaf people care

ID 1465- What are the representations of deaf users regarding their access to the primary care system?

Elsha SINNAKUDDY [(1)], Nelly AZAIEZ [(2)]

(1) Département De Médecine Générale Université Paris Cité, Paris, France
(2) Unité D'informations Et De Soins Des Sourds Uniss . Assistance Publique-Hôpitaux De Paris . Hopital Pitié Salpêtrière, Paris, France

Context: In a healthcare system designed primarily by and for hearing people, access to quality care remains difficult for French Deaf people who speak French Sign Language (LSF).

Objectives: To explore deaf user's perceptions of their access to the primary healthcare system.

Methods: Qualitative study. Ten semi-structured interviews were conducted in French Sign Language (LSF) with deaf citizens. Data analysis was performed using IPA (Interpretative Phenomenological Analysis).

Results: Deaf citizens aspire to access common law in their outpatient care pathways. In practice, they must constantly compromise between quality care, autonomy, and respect for privacy. Medical consultations with hearing physicians become the scene of depersonalization of the deaf patient: stigmatization, infantilization, animalization, and discrimination create the foundation for a dysfunctional therapeutic relationship in which the patient invariably adapts to the physician. Deaf people seam to view health solely through the prism of the absence of symptoms or illnesses. They declare themselves to be in good health while associating their health with negative concepts. While the respondents expect a Deaf leader to change the system at the collective level, the hearing general practitioner remains identified as a lever for improvement at the individual level when he or she practices a patient-centered approach, even in the absence of mastery of LSF.

Discussion: The authors discuss a multifactorial inability for deaf people to express their feelings, linked to an ableist society where the social violence they experience remains invisible, fueling a climate of insecurity and a form of resignation. The study highlights the methodological limitations of intercultural research conducted here by investigators from the dominant group, particularly when the analysis is based on comments translated into the dominant language.

Conclusion: Deaf people live in a vulnerable system that seams to limit the expression of their vulnerability and to shape atypical representations of health. Their study requires an inclusive methodology integrating deaf researchers to guarantee the quality of intercultural research and to carry out data analysis directly in the language of the respondents (LSF).

ID 1445- What are the motivations of doctors who treat deaf patients in sign language?

Nelly AZAIEZ

Unité D'information Et De Soins Des Sourds, Uniss. Assistance Publique-Hôpitaux De Paris. Hopital Pitié Salpêtrière, Paris, France

Context: Deaf speakers of French Sign Language (LSF) belong to a linguistic and cultural minority that suffers from unequal access to primary care. The 1990s and the AIDS epidemic were the context for the awareness of institutions with the creation of the first specialized LSF care units (UASS). The first

generation of signing doctors working in these units, now numbering twenty-three are retiring. It is difficult to find replacements. One can wonder about the impact, in the medium term, of this shortage of signing doctors on the sustainability of UASS and access to quality primary care for the Deaf.

Objectives: To explore the perceptions that physicians have of their motivations to initiate, maintain or interrupt a care activity for Deaf patients in sign language.

Methods: Qualitative study. 18 semi-structured interviews were carried out with physicians concerned with sign language throughout France by two investigators. Data analysis was performed by IPA (Phenomenological Interpretation) after triangulating the data at three levels.

Results: There seems to be a decisional balance of health professionals, the result of which leads to initiating, maintaining or interrupting a care activity with Deaf patients. There is a balance between factors of narcissistic valorization (the founding experience generates fascination, indignation, and a sense of power which is accompanied by the emergence of archetypal savior traits with the intention of repairing the wrongs) and downgrading factors (the difficulties inherent in the healthcare system generate frustration, isolation, exhaustion, and a feeling of helplessness which is accompanied by the disillusionment of not being the expected savior).

Discussion: Caring for Deaf people highlights the societal value of the medical profession. The signing physician cares for the Deaf person by addressing their sociological deafness : In the promotion of autonomy, in the acceptance of the Deaf person whose cognitive and communicational specificities are taken into account; in the attempt to overcome the social obstacles experienced by the person.

Conclusion: The doctor seems to initiate, maintain or interrupt an exercise with the Deaf depending on the representation he has of his power to provide them with quality care.The caregiver takes on a role of savior in his practice with the Deaf.

ID 1384- Sexual Health of deaf sign language users of a French Deaf care unit

Sara-Léane RODRIGUES [(1)], Emilie WU [(1)], Kelly PERLAZA GIRALDO [(2)], Gladys IBANEZ [(3)], Nelly AZAIEZ [(2)]

(1) Département De Médecine Générale Sorbonne Université, Paris, France
(2) Unité D'information Et De Soins Des Sourds, Uniss. Assistance Publique-Hôpitaux De Paris, Hôpital Pitié Salpêtrière, Paris, France
(3) Sorbonne Université, Inserm, Institut Pierre Louis D'epidémiologie Et De Santé Publique, Iplesp, Paris, France

Context: 2025 marks in France the 20th anniversary of the promulgation of the law for equal rights and opportunities and the 30th anniversary of the first Deaf unit providing care in sign language. Since then, around twenty units offer Deaf sign language users the liberty to benefit from intelligible primary care consultations in order to promote equitable access to care. Teams of these units are mixed: deaf and hearing caregivers work fraternally to offer a caring environment where disability disappears, embracing humanity. The prevalence of sexually transmitted infections (STIs) keeps increasing. Their complications are multiple : hepatitis, infertility, cancers (Human Papilloma Viruses - HPV). In France, compared to the general population, deaf people experience poorer sexual health. Studies show limited access to information due to illiteracy and language barriers. Their reporting of STIs is higher. Deaf women experience 2 to 3 times more sexual violence and more than a third who have been pregnant report having had an abortion. Deaf seem to be less informed about HPV and its preventive vaccination.

Objectives: To describe the sexual health and to estimate the HPV vaccination of deaf sign language users of a French Deaf care unit.

Methods: Quantitative, descriptive, retrospective, unicentric cohort study with 8 substudies. Data collected from 5000 adult deaf patients' medical reports from a French Deaf care unit from 2004 to early 2025 (sociodemographic characteristics, medical history, Contraceptive method, STIs screening and diagnosis, abortion history, personal history of violence.

Results: At abstract submission, the study is in the data collection phase. The results presented are intermediate outcomes. We hypothesize high rates of STIs and abortions, low rates of HPV vaccination. Overexposure to violence might be an associated risk factor.

Discussion: This study will describe the state of health of the deaf population and may propose ways to improve medical practices, particularly in terms of prevention and early diagnosis, which could be objectively validated by a new prospective study.

Conclusion: The implementation of effective public health policies requires a thorough understanding of the health status of target populations. We encourage the development of national and international collaborative studies in deaf people's health.

ID 1376- Cardiovascular risk and diabetes mellitus type 2 of deaf sign language users of a French Deaf care unit.

Fanny AMZALLAG [(1)], Eloise LASNE [(1)], Kelly PERLAZA GIRALDO [(2)], Nelly AZAIEZ [(2)], Gladys IBANEZ [(3)]

(1) Département De Médecine Générale Sorbonne Université, Paris, France
(2) Unité D'information Et De Soins Des Sourds, Uniss. Assistance Publique-Hôpitaux De Paris, Hôpital Pitié Salpêtrière, Paris, France
(3) Sorbonne Université, Inserm, Institut Pierre Louis D'epidémiologie Et De Santé Publique, Iplesp, Paris, France

Context: 2025 marks in France the 20th anniversary of the promulgation of the law for equal rights and opportunities and the 30th anniversary of the first Deaf unit providing care in sign language. Since then, around twenty units offer Deaf sign language users the liberty to benefit from intelligible primary care consultations in order to promote equitable access to care. Teams of these units are mixed: deaf and hearing caregivers work fraternally to offer a caring environment where disability disappears, embracing humanity. Cardiovascular diseases are the leading cause of death globally. In France it represents the 2nd leading cause of mortality with 25% of deaths. The global diabetes prevalence has risen to 14% (France 6%) with multiple medical and economic consequences. Scientific data concerning deaf people are scarce. They are thought to have more pronounced cardiovascular risk factors and higher diabetes-related morbidity.Significant difficulties in monitoring and managing these diseases could be linked to the language barrier and their low level of health literacy.

Objectives: To estimate the prevalence of cardiovascular risk factors, diabetes mellitus type 2 and its severe complications of deaf sign language users of a French Deaf care unit.

Methods: Quantitative, descriptive, retrospective, unicentric cohort study with 8 substudies. Data collected from 5000 adult deaf patients' medical reports from a French Deaf care unit from 2004 to early 2025 (sociodemographic characteristics, personnel and family medical history and cardiovascular risk factors, diabetes type, glycated hemoglobin, complications, médication).

Results: At abstract submission, the study is in the data collection phase. The results presented are intermediate outcomes. We hypothesize a cardiovascular excess morbidity with higher biological markers, an advanced diagnostic stage and the presence of complications.

Discussion: This study will describe the state of health of the deaf population and may propose ways to improve medical practices, particularly in terms of prevention and therapeutic education, which could be objectively validated by a new prospective study.

Conclusion: The implementation of effective public health policies requires a thorough understanding of the health status of target populations. We encourage the development of national and international collaborative studies in deaf people's health.

ID 1363- Mental Health of deaf sign language users of a French Deaf care unit

Clara FAVREL [(1)], Kelly PERLAZA GIRALDO [(2)], Nelly AZAIEZ [(2)], Gladys IBANEZ [(3)]

(1) Département De Médecine Générale Sorbonne Université, Paris, France
(2) Unité D'information Et De Soins Des Sourds, Uniss. Assistance Publique-Hôpitaux De Paris, Hôpital Pitié Salpêtrière, Paris, France
(3) Sorbonne Université, Inserm, Institut Pierre Louis D'epidémiologie Et De Santé Publique, Iplesp, Paris, France

Context: 2025 marks in France the 20th anniversary of the promulgation of the law for equal rights and opportunities and the 30th anniversary of the first Deaf unit providing care in sign language. Since then, around twenty units offer Deaf sign language users the liberty to benefit from intelligible primary care consultations in order to promote equitable access to care. Teams of these units are mixed: deaf and hearing caregivers work fraternally to offer a caring environment where disability disappears, embracing humanity. Mental Health is a Global Public Health Issue. In France, 20% of the population is affected by a mental illness and its psychotropic medicines consumption continues to increase. Deaf sign language users present a multifactorial vulnerability. Research shows excessive psychiatric morbidity with higher rates of suicidal throughs (x5) and attempted suicide(x3). Deaf sign language users experience social isolation and exhaustion due to illiteracy and language barriers. These social environment factors lead to feelings of loneliness and situational anxiety and depression.

Objectives: To describe the mental health and to identify associated factors of deaf sign language users of a French Deaf care unit.

Methods: Quantitative, descriptive, retrospective, unicentric cohort study with 8 substudies. Data collected from 5000 adult deaf patients' medical reports from a French Deaf care unit from 2004 to early 2025 (sociodemographic characteristics, medical history, suicidal behavior, family mental health history, addictive behavior, mental health treatments, personal history of violence).

Results: At abstract submission, the study is in the data collection phase. The results presented are intermediate outcomes. We hypothesize a higher psychotropic medicines medication and excessive rates of suicidal throughs. Overexposure to all kinds of violence might be an associated factor.

Discussion: This study will describe the state of health of the deaf population and may propose ways to improve medical practices, particularly in terms of mental health issues screening, which could be objectively validated by a new prospective study.

Conclusion: The implementation of effective public health policies requires a thorough understanding of the health status of target populations. We encourage the development of national and international collaborative studies in deaf people's health.

ID 1346- Diagnosis screening programs participation and neoplasm staging at diagnosis of deaf sign language users of a French Deaf care unit

Camille LE GALL [(1)], Majvina-Banu MOUGAMADOU BARACK [(1)], Kelly PERLAZA GIRALDO [(2)], Nelly AZAIEZ [(2)], Gladys IBANEZ [(3)]

(1) Département De Médecine Générale Sorbonne Université, Paris, France
(2) Unité D'information Et De Soins Des Sourds, Uniss. Assistance Publique-Hôpitaux De Paris, Hôpital Pitié Salpêtrière, Paris, France
(3) Sorbonne Université, Inserm, Institut Pierre Louis D'epidémiologie Et De Santé Publique, Iplesp, Paris, France

Context: 2025 marks in France the 20th anniversary of the promulgation of the law for equal rights and opportunities and the 30th anniversary of the first Deaf unit providing care in sign language. Since then, around twenty units offer Deaf sign language users the liberty to benefit from intelligible primary care consultations in order to promote equitable access to care. Teams of these units are mixed: deaf and hearing caregivers work fraternally to offer a caring environment where disability disappears, embracing humanity. Cancer is the leading cause of death in France and justifies national organized screening programs, but general population participation rates remain low 48% for breast cancer, 34% for colorectal cancer, and 59% for cervical cancer. Deaf sign language users present a multifactorial vulnerability. Illiteracy and language

barriers lead to exclusion from prevention campaigns and limited access to mass media. The literature shows lower participation in some organized screenings as well as for some cancers a more advanced-stage at the time of diagnosis.

Objectives: To estimate French national diagnosis screening programs participation and to describe neoplasm staging at diagnosis of deaf sign language users of a French Deaf care unit.

Methods: Quantitative, descriptive, retrospective, unicentric cohort study with 8 substudies. Data collected from 5000 adult deaf patients' medical reports from a French Deaf care unit from 2004 to early 2025 (sociodemographic characteristics, medical history, screening programs participation. If cancer : target organs, diagnostic staging, remission information, cancer risk factors, cancer family history).

Results: At abstract submission, the study is in the data collection phase. The results presented are intermediate outcomes. We hypothesize lower participation in screenings and a more advanced diagnostic stage than the general population, consistent with scientific publications.

Discussion: This study will describe the state of health of the deaf population and may propose ways to improve medical practices, particularly in terms of prevention, which could be objectively validated by a new prospective study.

Conclusion: The implementation of effective public health policies requires a thorough understanding of the health status of target populations. We encourage the development of national and international collaborative studies in deaf people's health.

Dermatology

ID 1631- Training of general practitioners in dermoscopy: systematic literature review

Erwan CLERGEOT [1] , Paul AUJOULAT [2]

(1) Interne, Brest, France
(2) Chef De Clinique, Brest, France

Context: Dermoscopy is a non-invasive skin examination technique that uses a dermoscope. Its effectiveness is well established for the early diagnosis of melanoma and for the evaluation of skin lesions in primary care. However, its integration into the daily practice of general practitioners (GPs) remains limited, partly due to insufficient training.

Objectives: The objective of this study was to provide an overview of dermoscopy training programs for general practitioners reported in the literature.

Methods: A systematic literature review was conducted using the PubMed and Cochrane databases. Eligible studies described dermoscopy training for general practitioners or GP trainees. Excluded were literature reviews, studies focusing solely on teledermoscopy, artificial intelligence, or specific dermatological conditions. Methodological quality was assessed using the Cochrane Risk of Bias tool for randomized controlled trials and the Newcastle-Ottawa Scale for observational studies.

Results: Eighteen studies were included. Six main themes emerged: training content, format, duration, outcome measures, timing of evaluation, and prior training. Dermoscopy training improved knowledge, diagnostic confidence, and clinical impact among general practitioners. All studies reported post-training improvement.

Discussion: This review shows that, regardless of format, dermoscopy training significantly enhances the knowledge, diagnostic confidence, and clinical practice of general practitioners. Some studies demonstrated reductions in unnecessary biopsies and referrals to specialists. The included studies, however, presented methodological limitations such as selection bias, lack of long-term follow-up, and absence of local data. These remained obstacles to a generalization of the results.

Conclusion: This literature review evaluated dermoscopy training for general practitioners. It showed that dermoscopy training allowed an improvement in diagnostic knowledge, clinical confidence, and the use of dermoscopy in daily

practice, regardless of the training format. The findings support the implementation of structured training programs combining theoretical input, clinical cases, and simple visual tools. Teaching dermoscopy in general practice could represent a lever to improve the early detection of skin cancers and to optimize the management of pigmented lesions. Its more systematic integration into initial and continuing medical education curricula could contribute to more effective patient care. Progressive integration of such training into GP residency curricula appears relevant.

Corresponding author: Erwan Clergeot, erwan.clergeot@yahoo.fr

ID 1591- Highlighting of a potential effect of melanoderma on the diagnostic abilities of general practitioners in children with atopic dermatitis

Nana TCHAN A, Bastien BOURRION, Caroline HUAS

Uvsq, Paris, France

Context: General Practitioners (GP) frequently encounter Atopic dermatitis (AD) as it's the most common dermatologic children's disease. Black skins have particularities that change the way dermatologic diseases looks. It has been shown in international studies that "migrans erythema" and "pityriasis versicolor" were more difficult to diagnosed due to this. There is an under-representation of melanodermic patients in pedagogic supports (<2% in the SAURAT, <12% in American atlas)

Objectives: The primary endpoint was the rate's comparison of diagnosis of eczema on melanodermic patients vs on leucodermic patients

Methods: A quantitative multicentric analytic cross-sectional study was run. This work took the participation of 54 GP working in French metropolis. Regional recruitment of the first 8 doctors appearing on Google, using a computer with no browsing history. The survey was tested beforehand and consisted in 2 parts: 1/ descriptive on GP 2/ iconographies with 7 photos of children seen in consultation (leucodermic children (n=2), melanodermic (n=4), distractor (n=1)). Photos were presented without clinical context, one per page without possibility of backtracking. Participants knew that the study focused on dermatology in melanodermic children, but not on DA. . Numbers of subjects to be included = 53. Responses were coded in « good », « false » and « don't know ». The « don't know » category was counted as « false ».

Results: Of the 65 participants, 54 were included in the analysis (378 responses). The analysis focused on 324 responses after excluding the distractor. Rate of incorrect diagnosis were 35,19% on white patients and 86,57% on melanodermic patients – difference statistically significant ($p < 0,0001$)

Discussion: This study's strength are: statistical methods with calculation of sample size and statistical power, original iconographies and impossibility of backtracking. Its limitations are the number of iconographies proposed, a possible selection bias. This study is questioning the loss of chance of melanodermic children toward eczema treatment

Conclusion: AD is children's most frequent skin's disease. Thus, GP are meant to make the diagnosis of it daily. However, the lack of diversity and learning's methods way too stigmatizing during health studies leads to wanderings, errors and diagnosis delayed when diseases occurred on melanodermic children.

ID 1594- Treatment of mild to moderate acne in patients with dark skin: a systematic review of the literature

Khadyja SYLLA

Sorbonne Université, Paris, France

Context: Acne is a common condition. In individuals with dark skin, it is often associated with post-inflammatory hyperpigmentation, which can affect quality of life. However, there are no specific xxx recommendations for this population.

Objectives: What treatments are effective for mild to moderate acne in individuals with dark skin?

Methods: A systematic review of the literature (SR) was conducted in accordance with PRISMA guidelines. The Embase and Medline databases were searched from January 1995 to March 1, 2024. Articles were selected using a double-blind method, first by reading the titles, then the abstracts, and finally the full texts. The articles included had to evaluate drug treatments for mild to moderate acne in patients with dark skinned. Dark skinned was defined with phototype IV to VI Fitzpatrick and/or of Afro-Caribbean, African-american, or sub-Saharan African origin. The ROBIS, ROBINS1, and ROB2 grids were used to assess quality. Finally, efficacy measured by changes in acne grade, lesions, post-inflammatory hyperpigmentation, and tolerance were extracted.

Results: 1,928 references were identified, 1,738 of which were excluded after reading the titles and abstracts. Sixteen studies were selected for full-text review, including eight post-hoc analyses of randomized controlled trials, two randomized controlled trials, six prospective studies. The included studies focused exclusively on topical treatments. The quality of the studies was low. There was little data on the use of benzoyl peroxide alone. Retinoids, azelaic acid, and combinations including benzoyl peroxide appear to be effective against acne and post-inflammatory hyperpigmentation, with good tolerability.

Discussion: The literature on acne treatment in people with dark skin remains limited, and there is a lack of studies of good methodological quality, limiting the generalizability of the results of this SR. The heterogeneity of the studies prevented the performance of a meta-analysis. In addition, the absence of articles evaluating cyclins and other oral treatments is a significant limitation.

Conclusion: Given the prevalence of acne and the specific characteristics of dark-skinned patients consulting general practitioners, it seems necessary to promote high-quality research to address the possible specificities of treatment in this population.

Corresponding author: Khadyja Sylla, khadyja.sylla@sorbonne-universite.fr

ID 301- Representations and future prospects for the use of dermatoscopes in skin cancer screening by general practitioners in XXX.

Aurore TRAMEÇON [1] , Constance LE GOFF [2]

(1) Ur7479 Spurbo, Département De Médecine Générale, Université De Bretagne Occidentale, Brest, France
(2) Université De Bretagne Occidentale, Brest, France

Context: Skin lesions are a frequent reason for seeking medical care. In XXX, the incidence of melanoma reached three times the national incidence, making early detection essential. The declining number of dermatologists, population ageing and the development of digital tools, including teledermatology, have contributed to the rise of dermoscopy in general practice. It broadens the scope of competence of general practitioners (GPs).

Objectives: To explore the perceptions and perspectives of GPs regarding the use of dermatoscope in the screening of skin cancers in primary care.

Methods: A qualitative study using semi-structured interviews was conducted with GPs who owned and used a dermatoscope. The interview guide explored the place of dermatology in their daily practice, their motivations for acquiring a dermatoscope, and how its use had shaped their diagnostic confidence, workflow, and patient interactions. Verbatims were analyzed using an approach informed by grounded theory.

Results: GPs described the dermatoscope as an object of pleasure and constraint, of reassurance and fear of exceeding their limits. For GPs, it reduced diagnostic uncertainty and provided a sense of security when evaluating ambiguous lesions. This increased confidence helped them feel more legitimate in managing dermatological complaints. They feel that it enhanced patients' trust and conveyed the impression of a more thorough examination, improving acceptance of medical decisions like referral or monitoring. Beyond reassurance, dermatoscopy improved patient pathways by facilitating triage, accelerating referrals when needed, and helping GPs assess the urgency of lesions. The notion of pleasure was linked to the diversity of practice that this gave them. The anticipated integration of AI into dermatoscopic assessment was viewed as a

promising tool to further strengthen diagnostic accuracy.

Discussion: For GPs, using a dermatoscope seems to have more interests than limits. By reducing uncertainty and diversifying GPS practices, the dermatoscope could help prevent professional exhaustion. As it redefins the role of GPs in skin cancer screening, it would be interesting to explore dermatologists' views on the contribution of the development of dermatoscopy in general medicine.

Conclusion: Early dissemination of dermatoscopic training and raising patient awareness of the role of GPs in skin screening are key levers for strengthening skin cancer prevention in XXX.

ID 898- Persistent urticarial lesions as a manifestation of urticarial vasculitis

Amandine Isabelle Marie POUPAR [(1)] , Iris RIVADENEIRA QUEIRUGA [(2)], Patricia Maria PITA DE NAVASQÜES [(3)]

(1) O Portadego Health Center, A Coruña, Espagne
(2) Perillo Health Center, A Coruña, Espagne
(3) Acea De Ama Health Center, A Coruña, Espagne

Context: Urticarial vasculitis (UV) is a type of small-vessel vasculitis that can resemble common urticaria. Due to its rarity, it poses a diagnostic challenge given its possible clinical behavior and implications.

Methods: A healthy 29-year-old woman with a history of atopic dermatitis in childhood visits her family doctor due to a 6-month history of weekly outbreaks of pruritic erythematous wheal-like lesions over the entire body surface, lasting more than 48 hours despite treatment with corticosteroids and antihistamines, and leaving behind violaceous residual marks. She also presents, following the intake of dexketoprofen, with facial and plantar angioedema, for which her physician refers her to the hospital emergency department after administering intramuscular adrenaline. A general blood test reveals normal platelet counts, immunoglobulin levels, and tryptase values. She is advised to avoid nonsteroidal anti-inflammatory drugs (NSAIDs) and referred to an allergy specialist. After three months, with persistent urticarial-type lesions despite high doses of corticosteroids and antihistamines, she is evaluated in the Allergy Department, where montelukast is added and new blood work is requested. Given normal complement levels but elevated antinuclear antibodies (ANA) and acute-phase reactants, she is referred to Dermatology for a skin biopsy. The biopsy result is consistent with urticarial vasculitis. She begins treatment with omalizumab, showing favorable progress.

Originality: In this clinical case, although complement levels were normal and no systemic involvement was present, the lack of response to conventional treatments required the introduction of a biologic agent. Moreover, worsening secondary to NSAID administration is

Lessons learned and future implication: To prevent unnecessary treatments and clinical worsening, it would be advisable to perform an early punch biopsy and order tests for acute-phase reactants and ANA at the primary care level.

Discussion: Early evaluation by Dermatology may be a key tool for prompt diagnosis, given that many cases mimic common urticaria.

Conclusion: It is important to emphasize the need to recognize persistent urticarial lesions as a potential manifestation of vasculitis through early biopsy, in order to avoid systemic deterioration and ineffective overtreatment.

Corresponding author: Amandine Isabelle Marie Poupar, amandineisabellemariepoupar@gmail.com

ID 475- Tele-expertise: perspectives and motivations of general practitioners using a tele-expertise platform for dermatological advice

Tristan GARNIER [(1)] , Tu-Anh DUONG [(2)]

(1) Département De Médecine Générale, Sorbonne Université, Paris, France
(2) Dermatologie Générale Et Oncologique Hôpital Ambroise Paré Ap-Hp, Boulogne-Billancourt, France

Context: Facing delays and limited access to dermatologists, general practitioners (GPs) increasingly rely on tele-expertise.

Objectives: This study analyzes the geographical distribution of GPs using an hospital's dermatologic tele-expertise network (TLX-N) and the factors influencing its use.

Methods: A quantitative descriptive study was conducted using responses to a 23 items online questionnaire sent, between april and may 2024, to GPs who had used the platform at least once since 2022. The postal codes were used to locate the respondents from the different TLX-N medical centers. Comparative analyses (Wilcoxon-Mann-Whitney, Chi2) were performed to identify factors influencing the use of TLX-N from GPs inside or outside its perimeter of action. A multivariate analysis (logistic regression) was conducted on selected variables based on Akaike's information criterion, to identify factors influencing the frequency of requests.

Results: A total of 274 GPs were contacted, 120 responses were included and analyzed. Respondents were mostly women (74,2%), established practitioners (70,8%), working in a multidisciplinary practice (84,1%), mean age was 37,6 ± 9,1 years old. The median distance to a TLX-N center was 5,1 km (IQR 1,6–9,4 km). In comparison to GPs inside the TLX-N perimeter of action, those outside were using tele-expertise by lack of nearby correspondents ($p<0,05$), they also expressed greater difficulties obtaining face-to-face consultations when required ($p<0,05$) and most of them discovered TLX-N thanks to the online platform's indexing system ($p<0,05$). GPs outside the perimeter (OR 2,49; CI 1,15-5,58; $p<0,05$) and using TLX-N for its educational aspect (OR 3,07; CI 1,17-8,52; $p<0,05$) were associated with higher use frequency.

Discussion: This study is innovant as few studies described a perimeter of action for tele-expertise centers. Despite a high response rate, some analyses lacked statistical power due to the limited sample size. Postal code localization had limited precision, but most respondents were close to TLX-N centers and not necessarily in medically underserved areas, consistent with previous studies from the same region.

Conclusion: Tele-expertise proved its effectiveness for GPs seeking a dermatological advice, although its implementation must be tailored to the diverse needs across the territory. Keywords : Telemedicine, general practice, primary care, dermatology.

Diabetes

ID 1824- Did the mandatory GLP-1 receptor agonist prescription-support form introduced in France in February 2025 change general practitioners' prescribing?

Michaël ROCHOY [(1)] , Pierre LHOTELLIER [(2)], Jan BARAN [(3)], Sophie GAUTIER [(3)], Emmanuel CHAZARD [(3)]

(1) Univ. Lille, Outreau, France
(2) Univ. Lille, Desvres, France
(3) Univ. Lille, Lille, France

Context: Glucagon-like peptide-1 receptor agonists (GLP-1RAs) used in type 2 diabetes promote weight loss, which has led to international misuse. In France, misuse affected 1.3% of patients in 2024, according to data from the French national health insurance (FNHI) system. However, in February 2025, the FNHI introduced a 2-minutes mandatory prescription-support form for all doctors, requiring information it already holds (diabetes status, associated antidiabetic treatments). Because reimbursement indications (ITR) are more restrictive than marketing authorisation, this measure may encourage overprescription of metformin in previously intolerant patients...

Objectives: To assess whether the introduction of this mandatory form has been associated with changes in prescribing patterns for GLP-1RAs and metformin in ambulatory care.

Methods: We conducted a retrospective, descriptive, population-based study using open-access national reimbursement data from the FNHI (Médic'AM). All reimbursed non-insulin antidiabetic drugs dispensed in community pharmacies between January 2019 and July 2025 were included. Monthly numbers of reimbursed boxes of GLP-1RAs and metformin (alone or in combinations) were analysed. Prescribing volumes during the six months before and after February 2025 were analyzed.

Results: Between 2019 and 2024, reimbursed GLP-1RA dispensations increased from 3.1 to 6.3 million boxes annually, while metformin dispensations remained stable (31.5 to 32.1 million boxes). In the six months following implementation of the prescription-support form, monthly GLP-1RA dispensations increased by 9.0%, with no interruption of the prior upward trend. Over the same period, metformin dispensations increased by 2.6%, driven by metformin monotherapy (+3.9%); metformin reached its highest June–July levels in six years.

Discussion: Administrative measure did not reduce the use of GLP-1RAs and may have encouraged adaptive prescribing behaviours focused on compliance with reimbursement rather than clinical appropriateness. Main strength of our work is the use of comprehensive national reimbursement data, limiting selection bias. Main limitation is that we only know the reimbursement: there is no individual clinical indication, information on tolerance, compliance, prescriber characteristics... We also lack hindsight: this work will be completed to track changes in prescribing.

Conclusion: This untargeted administrative measure generated additional low-added value administrative workload, equivalent to approximately 10 full-time general practitioners for one year! Regulatory strategies targeting atypical prescriptions (to non-diabetic patients) may be more effective.

ID 1732- Description of the evolution of dispensing of non-insulin antidiabetic drugs in France from 2014 to 2024 based on data from the French national health insurance system

Marin BOMMELAER, Laëtitia GOSSELIN

Université De Paris Cité, Paris, France, Paris (15e), France

Context: Type 2 diabetes is a major and growing public health concern in France, with innovative therapies such as SGLT2 inhibitors (SGLT2i) and GLP-1 receptor agonists (GLP-1RAs) reshaping treatment recommendations.

Objectives: We aimed to describe the evolution of non-insulin antidiabetic drug prescriptions trends in France between 2014 and 2024.

Methods: We conducted a retrospective descriptive study based on the Open Medic database from French National Health Insurance, covering annual outpatient drug dispensing in pharmacies that were at least partially reimbursed. All patients who were dispensed at least one non-insulin antidiabetic drug between 2014 and 2024 were included. The primary endpoint of this study was the number of packages of non-insulin antidiabetic drugs dispensed in France between 2014 and 2024. Stratified analyses were conducted according to age group, gender and prescriber specialty.

Results: From 2014 to 2024, over 633 million boxes of reimbursed non-insulin antidiabetic drugs were dispensed. Metformin remained the most dispensed treatment during the study period, accounting for 42% of all non-insulin antidiabetic dispensed in 2024. Sulfonylureas declined steadily (from 23% in 2014 to 11% in 2024), while SGLT2i and GLP-1RAs grew sharply after 2019 and surpassed sulfonylureas by 2024, representing 18% and 11% of all non-insulin antidiabetic dispensed, respectively. Endocrinologists were quicker to prescribe these innovative therapies, which were also more commonly initiated in younger patients than other non-insulin antidiabetic drugs. Although dispensed volumes remained relatively stable, total expenditures increased by 66% between 2018 and 2024, with SGLT2 inhibitors and GLP-1 receptor agonists accounting for nearly 80% of antidiabetic drug costs in 2024.

Discussion: These findings illustrate rapid alignment of French clinical practice with international evidence supporting SGLT2i and GLP-1RAs. Their early predominance among endocrinologists and younger patients likely reflects cautious initial use of new therapies, followed by broader diffusion as familiarity increased. However, the widespread uptake of these high-cost agents raises concerns regarding long-term financial sustainability.

Conclusion: Over the study period, metformin remained the most frequently dispensed treatment. The introduction of SGLT2i and newer GLP1-ARs was accompanied by a decline in the use of

sulfonylureas. Despite relatively stable overall dispensing volumes, expenditures have increased substantially, driven by the higher cost of innovative treatments.

ID 1589- Representations of type 2 diabetic patients over the age of 65 regarding continuous glucose monitors in general practice in Ile-de-France

Mathilde HEC

Sorbonne Universite, Paris, France

Context: The growing prevalence of diabetes and the increase in the number of elderly people pose challenges for the future. This is happening in a context of digital expansion in healthcare through new technologies such as continuous glucose monitors (CGMs). The perceptions of type 2 diabetic patients regarding digital tools have been little studied, particularly the perceptions of people over the age of 65.

Objectives: Study the perceptions of patients over 65 years of age with type 2 diabetes regarding CGMs.

Methods: The study was qualitative research based on grounded theory. The population of interest consisted of people over the age of 65 with type 2 diabetes who were eligible for CGMs and had a general practitioner. Recruitment was carried out using theoretical sampling. Twelve semi-structured interviews were conducted with audio recording and triangulation until data saturation was achieved. An explanatory model with a scheme was created.

Results: Diabetes status and digital development are two factors contributing to discrimination felt by participants and their social exclusion. Mastering new technologies, particularly CGMs, enables elderly people with diabetes to maintain their independence and integrate into society. However, there are still limitations to the autonomy provided by sensors: measurement reliability, obsession with numbers, and dependence on installation. Finally, the fear of dehumanisation is less than that of a decline in medical demographics and is offset by trust in the attending physician.

Discussion: The strengths of the study are: its relevance to the current context and its rigorous methodology (length of interviews, triangulation, logbook monitoring). The limitations are: a possible social desirability bias and the principal investigator's lack of previous experience. Innovative study with a population that is rarely surveyed.

Conclusion: The perception of elderly diabetic patients appears to be positive regarding CGMs, which seem to offer a solution for improving their quality of life. Support and consideration of the criteria for recommending CGMs to elderly diabetic patients must be provided. General practitioners appear to be key players in supporting elderly patients in adopting these new technologies.

ID 1524- Long-term Effectiveness of the National Diabetes Quality Assessment Program on Clinical and Economic Outcomes in Patients with Multiple Chronic Conditions

Hyeonseok KOH [(1)] , Belong CHO [(2)]

(1) Graduate School Of Public Health, Seoul National Unversity, Seoul, Corée, République de
(2) Department Of Family Medicine, Seoul National University Hospital, Seoul, Corée, République de

Context: South Korea has implemented the pay-for-performance program based on the Health Insurance Review and Assessment Service (HIRA) quality assessment for over a decade.

Objectives: This study examined the long-term clinical and economic effectiveness of the National Diabetes Quality Assessment Program (NDQAP) for patients with diabetes and multiple chronic conditions (MCCs).

Methods: From the National Health Insurance Claims Database, 428,911 individuals with diabetes

who visited a primary care clinic from 1 July 2015 to 30 June 2016 were included and followed up until 31 December 2023. Subgroup analyses were conducted according to the presence of comorbid hypertension and dyslipidemia. The primary exposure was the quality of primary care institutions, defined by accreditation status and performance on quality indicators. Cox proportional hazards models estimated hazard ratios (HRs) and 95% confidence intervals (CIs) for diabetes complications and all-cause mortality. Medical costs were analyzed using Gamma generalized linear models.

Results: During the mean follow-up duration of 7.2 years, utilization of high-quality institutions was associated with a decreased risk of macrovascular complications and all-cause mortality. Consistent results were observed across all patient groups. Among patients with diabetes, hypertension, and dyslipidemia, individuals managed in high-quality institutions had a lower risk of all-cause mortality (HR 0.95; 95% CI 0.92–0.97), cardiovascular disease (HR 0.93; 95% CI 0.92–0.95), cerebrovascular disease (HR 0.93; 95% CI 0.91–0.95), peripheral vascular disease (HR 0.90; 95% CI 0.88–0.91), and heart failure (HR 0.90; 95% CI 0.88–0.93) than those who were not managed in high-quality institutions. Individuals managed in institutions with higher quality indicator scores incurred 14–18% lower total medical costs.

Discussion: The achievement of NDQAP indicators was associated with a decreased risk of diabetes complications, all-cause mortality, and long-term healthcare expenditures for patients with MCCs.

Conclusion: These findings support strengthening financial incentives for institutions that improve health outcomes and reduce healthcare costs in South Korea.

ID 1357- The role of family doctor in psychical rehabilitation of the patients with diabetes mellitus

Carmen Iliana BUSNEAG [1] , Adriana Larisa MATEI [2]

(1) Spiru Haret University, Bucharest, Roumanie
(2) Family Medicine Resident, Bucharest, Roumanie

Context: Diabetes mellitus is a complex chronic disease that requires continuous medical care and in which, beyond glycemic control. many strategies to reduce multifactorial risks are required. Moderate or intense physical exercise is recommended at all stages of diabetes, being able to prevent complications of the disease and optimize the quality of life of patients.

Methods: The present paper specifies the practical aspects of establishing and individualizing kinetic programs in diabetes in a primary care setting, trying to answer the questions: how much, how and in what way is physical rehabilitation in diabetic patients performed? The principles of the kinetic programs are presented, but also the basic rules for the application of the rehabilitation program and the ways of achieving the isotonic or isometric effort in these patients. The contraindications but also the precautions related to the physical training of diabetic patients cannot be missing.

Originality: This topic is extremely little known in the specialized literature and is very little applied in the practice of the family doctor. But the efficiency of the recovery program proposed in the paper is very high, therefore we try to share our practical expe

Lessons learned and future implication: The lesson to be learned from this work is that the family doctor must know and recommend an adapted, supervised and progressive physical exercise program for each patient with diabetes under his care.

Discussion: Physical rehabilitation is an integral part of Diabetes Self Management Education and Support (DSMES) and should be encouraged in all patients with diabetes! Physical exercise is indicated in all stages of DM and is part of the therapeutic objectives in DM: -prevention of complications -optimizing the quality of life - movement therapy acts on the pathogenic links of DM - into the SMART program (specific, measurable, achievable, realistic, in time)

Conclusion: The implication of family doctor in the supervised psysical training programms, strictly individualized, progressive and applied as a true lifestyleof patients with diabetes mellitus,along with diet and recommended medication will reduce the complications of the disease, will significantly improve the quality of life of these patients and will increase their life expectancy.

ID 903- Patients' Understanding of HbA1c and Its Role in Type 2 Diabetes Self-Management: A Qualitative Study

Thomas BALICKI, Charles CAUET

Faculté De Médecine De Lille, Lille, France

Context: Type 2 diabetes melitus (T2DM) affects 5.6% of French population with an increasing prevalence. HbA1c is the standard biomarker for long-term monitoring in T2DM. While its biomedical value is well established, much less is known about how patients perceive HbA1c and how they integrate it into their daily self-management. Understanding these representations is essential for improving therapeutic education and shared decision-making in primary care. This study explores the personal meanings and emotional representations patients attribute to HbA1c, capillary blood glucose monitoring, and continuous glucose monitoring (CGM).

Objectives: Exploring how patients with T2DM understand and interpret HbA1c, how they relate it to their daily glucose self-monitoring practices, and how these perceptions shape their sense of control and autonomy.

Methods: This qualitative study, inspired by grounded theory, was conducted between August 2023 and April 2024. Eleven semi-structured interviews were carried out with adults living with T2DM, recruited in general practice and a rehab center. Interviews were audio-recorded, transcribed verbatim and analysed via open, axial, and selective coding with methodological triangulation.

Results: HbA1c is perceived as important: a tool for knowledge and control, a target to aim. Self-monitoring of blood glucose allows daily monitoring and adaptation of lifestyle. CGM appears more precise but for complex cases. HbA1c limits are the inability to act on it and the feeling to be left unprotected from T2DM complications. The core idea was the refusal to endure the disease as the focal point from positive perceptions of HbA1c: helping keeping control of diabetes, and negative ones with the will to preserve freedom and autonomy.

Discussion: Patients attribute strong symbolic value to HbA1c. Its lack of immediate actionability explains why daily capillary monitoring remains emotionally and practically essential. Therefore, those results are questioning the recommendations about T2DM monitoring. Most importantly, it questions the goal of patients to reduce the burden of the disease and its treatments with regards to the actual guidelines.

Conclusion: This study highlights perceptions, concerns and expectations from type 2 diabetes patients, that we hope will help professionals providing better patient education and patient centered approach of care.

ID 307- Cardiovascular risk estimation in patients with type 2 diabetes mellitus: clinical classification versus SCORE2-Diabete.

Willy PHUNG, Marine COCHEREL, Marine HANSER, Alexandre MALMARTEL

Université Paris Cité, Paris, France

Context: Type 2 diabetes mellitus (T2DM) is a major determinant of cardiovascular (CV) diseases. Statins significantly reduce CV events in high- and very high-risk patients. The 2021 European Society of Cardiology (ESC) guidelines classified most patients with T2DM in primary prevention as having "high" or "very high" CV risk according to diabetes complications. In contrast, the 2023 ESC guidelines introduced the SCORE2-Diabetes, which integrates diabetes-specific parameters (such as age, gender,

HbA1c…) to enable more individualized CV risk assessment.

Objectives: To compare (1) CV risk estimations according to ESC 2021 and SCORE2-Diabetes classifications, and (2) the proportion of patients with statin indication (high and very high risk), in an ambulatory population of patients with T2DM.

Methods: We conducted a retrospective observational study across 15 general practices. Data from pro.ameli.fr and electronic medical records of the investigating general practitioners were used to collect diabetes- and CV-related characteristics of patients aged 40–69 years with T2DM and no prior CV disease. Agreement between the ESC 2021 and SCORE2-Diabetes classifications was evaluated using Cohen's kappa coefficient. Comparisons were performed with McNemar's test and multivariable logistic regression.

Results: Among 817 patients screened, 209 patients with T2DM were included (men: 45%; mean age: 57 ± 9 years; mean HbA1c: 7.8 ± 1.6%). According to ESC 2021, 42% of patients were classified as high or very high CV risk, compared with 34% using SCORE2-Diabetes (p=0,004). Agreement between classifications was poor (κ= 0.16). Discrepancies were mainly driven by the inclusion of age ($p < 0.01$) and blood pressure ($p = 0.01$) increasing CV risk in the SCORE2-Diabetes, and by the albumin–creatinine ratio ($p < 0.01$) in ESC 2021.

Discussion: This study provides the first comparison of ESC 2021 and SCORE2-Diabetes risk classifications in a real-world ambulatory population. However, our sample may not be fully representative, and no randomized clinical trials have yet assessed statin prescription outcomes based on SCORE2-Diabetes.

Conclusion: Implementation of the SCORE2-Diabetes resulted in lower estimated CV risk and may reduce statin prescriptions among patients with T2DM in primary prevention. Further studies are warranted to evaluate the clinical, economic, and iatrogenic implications of such reclassification.

End of life

ID 2174- State of knowledge on French healthcare professionals' views regarding medical aid in dying

Gaëlle RAGOT, Paul AUJOULAT

Département Universitaire De Médecine Générale-Université De Bretagne Occidental, Brest, France

Context: Medical aid in dying (MAiD) remains illegal in France. In May 2025, however, the French National Assembly voted in favor of its legalization, primarily based on the conclusions of Report No. 139 of the National Consultative Ethics Committee and the Citizens' Convention.

Objectives: This study aims to provide an overview of current knowledge and healthcare professionals' views on medical aid in dying since the enactment of the Claeys–Leonetti law in 2016.

Methods: A systematic literature review was conducted using PubMed, Scopus, and HAL databases to identify articles published between 2016 and 2025 addressing medical aid in dying, euthanasia, and assisted suicide from the perspective of general practitioners. Study selection was performed independently by two reviewers using a double-blind process.

Results: A total of 206 articles were initially identified. After title and abstract screening, eight articles were included for analysis. The analysis was ongoing at the time of abstract submission.

Discussion: This study aims to contribute to a better understanding of French healthcare professionals' views on medical aid in dying. Future analyses may explore how these views relate to the indications proposed in Opinion No. 139 of the National Consultative Ethics Committee. Additional perspectives include considering the broader context of healthcare system constraints, such as access to palliative care and medical workforce distribution, as well as examining existing literature on requests for euthanasia and their evolution over time.

Conclusion: This article provides an overview of current knowledge on healthcare professionals' opinions regarding medical aid in dying, its legalization, and its implementation in practice. It

highlights the diversity of perspectives reported in the literature and lays the groundwork for future research exploring professionals' experiences, perceptions, and practical challenges related to this practice.

ID 2153- Evolving views on assisted dying among general practitioners in La Réunion : a grounded theory study

Frédérick MONIN, Anne-Charlotte BONNET

Ufr Santé/université De La Réunion, Saint-Denis, Réunion

Context: Assisted dying is a debate at the crossroads of legal, societal and medical issues in France. Representations of end-of-life care are shaped by cultural and religious frameworks. XXXXXXX is a culturally diverse, multi-faith setting where different traditions coexist and remain highly present in daily life. This makes it a relevant place to explore how GPs' representations of assisted dying evolve over time, in an environment where multiple factors likely to shape representations are simultaneously present.

Objectives: To explore how general practitioners' (GPs) representations of assisted dying evolve over time and to identify factors shaping this evolution.

Methods: Qualitative grounded theory study. Semi-structured interviews were conducted with qualified private-practice GPs living in the research setting for at least two years (June-October 2024). Sampling aimed at maximum variation (sex, age, origin, religious/spiritual beliefs, time living in the place, palliative care training). Analysis was iterative (open coding and integrative analysis) to build an explanatory model; four interviews were triangulated during open coding. Transcripts and the analysis were returned to participants for possible amendments; a reflexive logbook was kept.

Results: Eight GPs (4 women/4 men; mean age 58 years) were interviewed; theoretical saturation was reached after six interviews and confirmed with two additional interviews. Three influences shaped representations: personal beliefs (religious/spiritual/cultural), lived experiences (professional and personal end-of-life encounters), and the legislative framework. A salient paradox emerged: several GPs reported that their views had not changed, yet their narratives revealed shifts over time. These shifts included a movement toward patient-centred relational ethics ("care"), emphasising patient autonomy while recognising the conscience clause. Positions remained diverse, for example some considered assisted dying acceptable only in accredited centres rather than at home.

Discussion: The coexistence of "stability claims" with narrative change suggests that representations are dynamic and sometimes only partially conscious. This paradox can be understood as tension between institutional norms, lived experience and belief systems, helping to interpret ambivalence in clinical positioning.

Conclusion: In a plural cultural and religious environment, supporting GPs' reflective processes through ethics discussion spaces, training and strong palliative care resources may help them accompany patients with humanity and respect, especially if the legislative landscape changes.

Corresponding author: Anne-Charlotte Bonnet, annecharlottebonnet@yahoo.fr

ID 1653- Does training in palliative care improve the ability of GPs to identify palliative care patients within their practice?

Vladimir DRUEL, Denise USAUROU, Yohann VERGES, Marie Eve ROUGE-BUGAT

Département Universitaire De Médecine Générale De Toulouse, Toulouse, France

Context: Identifying palliative care needs in primary care is a significant challenge for general practitioners (GPs), particularly in anticipating the needs of patients and their families. Despite the availability of support tools in France (French National Authority for Health, 2016), these tools are often poorly known or underused. This study examines whether training in palliative care improves GPs' ability to identify palliative care patients.

Objectives: To evaluate the impact of palliative care training on the criteria used by GPs to initiate palliative care.

Methods: A quantitative study was conducted with an anonymous questionnaire distributed to GPs between January and March 2024. The questionnaire assessed the clinical criteria and tools used by trained and untrained GPs to identify palliative care situations, specifically comparing the use of PICT-FR, Pallia10, and the "surprise question" (“Would you be surprised if the patient were to die within the next 12 months?”). Descriptive and analytical analyses were performed using Chi-square and Student's t-tests.

Results: 196 physicians (39% response rate) participated. GPs trained in palliative care were more likely to use specific tools, such as Pallia10 and SPICT-FR (27% vs. 5%, p<0.01), while untrained GPs mainly relied on the "surprise question" (39%). The most commonly used criteria for identifying palliative situations were patient frailty and rapid disease progression (over 80%), with no significant difference between trained and untrained physicians. However, trained GPs more frequently used additional criteria, such as persistent symptoms (p=0.02) and inhalation pneumonia (p=0.01).

Discussion: This study highlights the importance of encouraging dialogue on palliative care in primary care, particularly in the context of end-of-life care. While training improved palliative assessments, familiarity with home-based care criteria remains limited, even among trained physicians. Additionally, much training occurs in hospital settings, which may not address home-based care needs adequately.

Conclusion: Training significantly improves the identification and assessment of palliative care situations in primary care. Early discussions with patients, families, and caregivers lead to more appropriate, respectful care aligned with patient wishes.

Corresponding author: Vladimir Druel, vladimir.druel@wanadoo.fr

ID 1810- Implementation of Assisted Dying: Advance Reflections of General Practitioners in the Champagne-Ardenne Region

Louison HERMENT, Vincent SANCHEZ

/, France, France

Context: Assisted Death (AD), adopted at first reading by the French National Assembly on May 27, 2025, is part of the ongoing evolution of end-of-life legislation.

Objectives: To assess General Practitioners’ (GPs) expectations regarding the implementation of AD based on the most recent version of the law.

Methods: A qualitative study inspired by grounded theory. Data were collected via semi-structured interviews with GPs practicing in the Champagne-Ardenne region.

Results: GPs perceive themselves as central actors in the implementation of AD, due to the trust-based relationships they maintain with their patients. They highlight the need to clarify practical conditions of application, as well as the necessity for dedicated structures and multidisciplinary teams. The legal framework is perceived as restrictive, with unclear eligibility criteria and a fifteen-day waiting period considered ill-suited to collegial decision-making processes. This practice is expected to generate a significant emotional burden and, in some cases, internal moral distress, requiring professional support and, at times, recourse to the conscience clause. Palliative care services remain essential stakeholders in patient management.

Discussion: A specific organizational model for AD may emerge in France, combining dedicated structures with a network of trained GPs, like the Swiss and Belgian models. The further development of palliative care appears necessary. AD confronts GPs with moral and ethical questioning, involving inner conflicts and uncertainty, linked to their values, personal experiences, and conceptions of care.

Conclusion: GPs are likely to be involved as first-line providers in coordination with end-of-life professionals. AD raises organizational, psychological, and ethical challenges, confronting GPs with their personal and professional values,

while maintaining the constant objective of respecting the physician–patient relationship.

Corresponding author: Louison Herment, louison.herment08@gmail.com

ID 101- When a Patient Dies: Inside the General Practitioner's Experience

Charles CAUET, Mederic PLE, Sabine BAYEN

District Of General Practice, Lille, France

Context: Death, increasingly medicalized and often hidden in Western societies, remains a central yet challenging experience in general practice. General practitioners (GPs), who accompany patients and families over time, are frequently confronted with loss, often without specific training in grief or end-of-life care. This proximity, combined with emotional exposure and professional demands, questions the meaning of care, the physician's humanity, and the resources needed to preserve professional balance.

Objectives: To explore how general practitioners in the Hauts-de-France region experience the death of their patients, and to identify its human, relational, and professional repercussions.

Methods: A qualitative study inspired by grounded theory was conducted among community-based general practitioners who had experienced the death of a patient. Ten semi-structured interviews were carried out between March 2024 and May 2025, recorded, transcribed anonymously, and analyzed through open coding and data triangulation. Conceptual categories were developed to construct an explanatory model. The study met COREQ quality criteria and complied with all ethical and data protection standards.

Results: Being a GP is a vocation involving daily confrontation with illness, suffering, and death. Physicians build deep relationships with patients, leading to emotional reactions—sadness, guilt, sometimes relief—depending on context. These experiences often provoke existential reflections and highlight the physician's vulnerability. To cope, GPs mobilize resilience strategies such as peer support, life balance, or personal beliefs. Experience and mentorship strengthen emotional intelligence and empathy, allowing physicians to transform these encounters into growth and deeper understanding of care. The patient's death thus becomes both a challenge and a formative experience shaping professional identity.

Discussion: Facing patients' deaths profoundly affects GPs, challenging their vocation and the boundary between personal and professional life. Emotional exposure can cause distress but also foster meaning and resilience. The lack of structured training supports the need for educational approaches that develop emotional competence and peer support.

Conclusion: A patient's death is not merely clinical but an existential experience shaping GPs' identity. Recognizing and supporting this process promotes empathy, resilience, and a more humanistic practice of medicine.

Finding help, in digital tools or humans

ID 1853- Oral and dental pathologies in children: development and evaluation of a tool for the general practitioner

Gal BENEDICTE, Cirella THOMAS

Dumg Montpellier Nimes, Montpellier, France

Context: Early childhood caries is a very common condition. Poor oral health can have multiple consequences in children. General practitioners play a fundamental role in follow-up and can have a decisive role in the prevention of pediatric oral health problems, even though they may not feel competent.

Objectives: The objective of this study is to determine whether providing an information sheet leads to an improvement in general practitioners' satisfaction and perceived competence in the management of oral and dental pathologies.

Methods: We developed guideline-based information sheets that are both concise and clear. A Microsoft Forms questionnaire was created and

distributed electronically to practicing general practitioners. At the end of the survey, they received the summary sheets. A second questionnaire was administered 4 to 6 months after the first. The data were analyzed using pivot tables.

Results: 31 general practitioners responded to the first questionnaire, and 24 to the second. 55% of respondents frequently addressed oral health. 52% of the participants reported frequently feeling unsettled by the topic, and 55% stated that they felt uncomfortable with it. Half of the respondents frequently referred children to a dentist. Self-assessment of satisfaction and competence regarding pediatric oral and dental pathologies revealed a mean score of 4/10. The mean score attributed to physicians' perceived need for training was 7.35/10. More than 90% of the sample acknowledged the usefulness of the questionnaire. After 6 months, satisfaction and perceived competence remained stable

Discussion: The material addresses a genuine need for training in routine clinical practice. The number of participants was insufficient to allow extrapolation of the results. Most respondents were clinical trainers, who are likely to be more involved in continuing medical education and teaching.

Conclusion: Oral and dental pathologies represent a major issue in pediatrics. The tool developed was considered useful by the physicians and wider dissemination would likely lead to improved management of these conditions.

Corresponding author: Cirella Thomas, thomas.cir@hotmail.fr

ID 1630- What are the experiences of caregivers acting as interpreters during the healthcare journey of the person they are assisting?

Sylvain HOM [(1)] , Camille TRUONG [(2)], Nelly AZAIEZ [(2)]

(1) Département De Médecine Générale, Sorbonne Université, Paris, France
(2) Unité D'information Et De Soins Des Sourds, Paris, France

Context: Being a caregiver and acting as an interpreter is a combination of two roles: the duty to help one's loved one is coupled with the need to transmit information between the doctor and the person being cared for. The complexity of these intertwined roles raises questions about communication challenges.

Objectives: To study the experiences of caregivers acting as interpreters in order to explore the different dimensions of assistance in situations of language barriers, and to understand the impact of these experiences on their health and quality of life.

Methods: Qualitative study. Ten semi-structured interviews were conducted with caregivers acting as interpreters by a researcher. Data analysis was carried out using an interpretive phenomenological approach.

Results: Like a savior, the caregiver acting as an interpreter assumes the transgenerational responsibility of caring for their non-native-speaking relative, whose vulnerability is compounded by the language barrier. Their mission is built and established in filial love and familial duty. The challenges are numerous, notably finding the right balance of closeness in the caregiving relationship, and their appropriate role, as a neutral interpreter, in medical consultations. The narcissistic reward of caregiving is uncertain: sometimes the devaluation fuels disappointment and burdens the caregiver, who seeks recognition; at other times, the rewards reinforce the caregiver's development of quasi-professional skills.

Discussion: The right balance of closeness in the triangular relationship between doctor, patient, and interpreter reveals three positions in the discourse: patient-centered, physician-centered, and interpreter-centered. The link between care and dependence is close when it comes to the transmission of information: between empowering the person being cared for and maintaining control through censorship, filtering, or the complete disclosure of information by the caregiver.

Conclusion: Preserving the autonomy of the person being cared for, requires a delicate balancing act in the dual role of caregiver and interpreter. The caregiver acting as an interpreter's introspection on their experiences seems to strengthen their sense of self-worth. Providing them with a space for discussion and the exchange of best practices to reflect on these challenges appears beneficial. It also seems relevant to examine the dynamics associated with the post-caregiving period.

Corresponding author: Sylvain Hom, sylvain.hom@gmail.com

ID 1671- The experiences of young adult caregivers in France: a qualitative study

Elodie BELOT, Carole JOHNSON, Chloé MORIN, Jean Christophe POUTRAIN, Denis PEREZ

Dumg, Toulouse, France

Context: A young adult caregiver is a person between the ages of 18 and 25 who regularly helps someone in their circle to cope with a physical or mental illness or disability. Few studies in France have examined their experiences.

Objectives: The primary objective is to understand the experiences of young adult caregivers in order to monitor them in general practice. The secondary objective is to identify the specific characteristics of this population that should be taken into account in general practice consultations.

Methods: Qualitative study with semi-structured individual interviews, inspired by grounded theory. It was conducted with eight young adults aged between 18 and 25 who were caregivers according to the MACA-YC 18 score categories. Recruitment was carried out using posters displayed in locations frequented by students and through caregiver associations on social media.

Results: The assistance provided has multiple consequences on the life of the young adult caregiver: consequences on their physical and mental health, on their development and personal growth, on their family, relationships, and place in society. This leads to overinvestment in the person being cared for and a desire to escape.

Discussion: This work has resulted in an explanatory model in the form of a diagram. Many different and varied concepts have been addressed in which the general practitioner plays a key role. However, this population is not very visible and is often overlooked. Strengths: originality in a topical and under-researched field. Diverse recruitment of caregivers and their pathologies. Limitations: few participants aged between 18 and 20 with relatives only within the family.

Conclusion: Other projects to improve screening and more comprehensive care, particularly through general practitioners, would appear to be necessary to improve the experience of young adult caregivers.

Corresponding author: Elodie Belot, elodie.belot@dumg-toulouse.fr

ID 1359- Analysis of adherence to the use of a rapid diagnostic test measuring CRP: a qualitative study among general practitioners in Franche-Comté

Charles GUILLERAULT

Ufc Ufr Santé-Université De Franche-Comté-Ufr Des Sciences De La Santé, Besançon, France

Context: In 2024, antibiotic prescriptions by general practitioners in France increased by 6.2%. France has become the second largest consumer of antibiotics in Europe, despite many awareness campaigns. The ICARE study, conducted among general practitioners in Franche-Comté, assessed the volume of antibiotic prescriptions after one year of using a rapid diagnostic test to measure CRP.

Objectives: At the same time, an ancillary qualitative study was conducted to analyse general practitioners' use of this rapid diagnostic test during consultations.

Methods: The qualitative study was conducted through semi-structured interviews with 25 general practitioners recruited after a reasoned sampling process. Data analysis was based on the grounded theory approach.

Results: Rapid CRP testing in the doctor's office represents an evolution in medical practice and

responds to the need to remove uncertainty and provide an objective result to guide patient care. The use of this tool improves the quality of care and contributes to the rational prescription of antibiotics. It strengthens the doctor-patient relationship by helping to educate patients on the proper use of antibiotics and improving adherence to the medical care offered. However, its effective use remains correlated with its acceptability by general practitioners, who must embrace this rapid diagnostic test.

Conclusion: Enhancing personal fulfilment through the use of a tool and responding to professional motivations (the shift towards evidence-based medicine) are driving greater uptake among general practitioners. A medico-economic study would provide arguments in favour of continuing the use of rapid diagnostic test and rolling it out on a larger scale.

ID 940- Feelings of caregivers of dependent adults under 60 years old

Magali MILANINI [(1)] , Mathilde LUCOT [(2)]

(1) Département De Médecine Générale D'aix-Marseille Université, Marseille, France
(2) Faculté De Médecine Générale D'aix-Marseille Université, Marseille, France

Context: In France, there are around 11 millions caregivers. Despite this number, the society's interest in caregivers is recent. Moreover, there are 2,2 millions dependent adults between 20 and 60. And there are only studies about how caregivers of dependent elderlies feel.

Objectives: Seeks how caregivers of under 60 years old dependent adults feel.

Methods: This is a qualitative study, done by semi-directed interviews of 10 caregivers, after recruitment by purposive sampling.

Results: Caregivers are new beings in evolution, especially because of the modifications of their relationships with the patient and medical staff. This produces changes in their personality with a state of hypervigilance and concerns about the future. Caregivers develop an ambivalence between their burden, inducing exhaustion, and total devotion towards the patient. But also caregiving leads them to be positive and develop their resilience. Their new status has a lot of consequences on their health, career, family and hobbies. Caregivers need to adapt their life every day. They become patient's experts and find helps around them. They regret the lack of respite solution.

Discussion: Our study is the first to study caregivers of under 60 years old dependent adults. There are many similarities between our study and the one about caregivers of dependent elderlies but also some specificities in our results, especially ambivalence.

Conclusion: The need of rest is a major requirement in the caregivers' life. They deplore the lack of these offers. They note the importance of best information on existing aids, with the creation of a single contact and administrative simplification.

ID 737- AutomédiQ: to shed the light on self-medication

Louis BRAUN [(1)] , Laure RIVET [(1)], Mélody MAILLIEZ [(2)], Sarah CHATEAUNEUF [(3)], Elodie CHARUEL [(3)], Hélène VAILLANT-ROUSSEL [(3)]

(1) Université Clermont-Auvergne, Clermont-Ferrand, France
(2) Université Paris Cité, Laboratoire De Psychologie Sociale, Paris, France
(3) Université Clermont Auvergne, Unité De Recherche Acceppt, Clermont-Ferrand, France

Context: Self-medication is a common practice that has been poorly studied in France. However, its prevalence is estimated at 67% worldwide. It can have a significant impact on patients due to drug interactions and adverse effects. Despite good practice recommendations, there is no validated French tool for studying it. Yet exploring it is essential in primary care in order to understand patients' practices.

Objectives: To create a validated tool for self-medication study : the AutomédiQ self-questionnaire.

Methods: A three step patient-centered method was used. First, the tool was created using a nominal group and validated by an expert group. Second, user testing was conducted with patients recruted from two community pharmacies and two general practices. It was conducted in two stages : patients answered the questionnaire using the “think-aloud method” and were invited to provide feedbacks after completion. Finally, with the contribution of a social psychologist, the tool was validated through an eDelphi method involving international french-speaking experts.

Results: AutomédiQ was designed as an online self-questionary accessible via QR code or web link. The nominal group composed of 17 professionals designed an initial questionnaire with 28 questions. The expert group's review narrowed the questionnaire down to 17 questions by transforming 11 questions into sub-questions exploring the methods, habits and determinants of self-medication. Four testing cycles were conducted, including three with patients. Finally the eDelphi process involved two cycles with the participation of 15 international experts in self-medication, questionnaire design and primary healthcare. This process led to the validation of the final version of AutomediQ.

Discussion: AutomédiQ's strength lies in its original design, which follows a rigorous approach and a validated method. It was developed with a focus on future patients. However, it does have some weaknesses. It focuses on pain to ensure acceptable length of completion. It will require a method adapted for people with limited computer skills and adjustments according to the national contexts of French-speaking countries.

Conclusion: AutomédiQ is the first validated self-questionnaire in French for studying self-medication for pain. An initial project using AutomédiQ is planned to assess its usability in large scale. Numerous studies will follow to shed light on self-medication practices.

ID 674- Reimagining multimorbidity care: The potential of digital twins in primary care

Khunsha FATIMA

University Of Warwick, Coventry, Royaume-Uni

Context: Multimorbidity is a global issue that places a significant burden on patients, healthcare providers, and the healthcare systems. Clinical guidelines and digital systems focus on single-disease management, leaving GPs to manage multimorbidity with limited support. In healthcare, digital twins(DT) are evolving digital models of patients, organs, or processes that continuously integrate real-time data, enabling simulation, prediction, and personalization of clinical decision-making. Hospital-based specialties have demonstrated the usefulness of DTs in predicting clinical outcomes and assisting in patient-specific decision-making.

Objectives: To appraise how DTs are being used across various clinical specialties To evaluate how this technology can be used in multi-morbidity in primary care(PC). To identify potential barriers to the adaptation of this technology.

Methods: This commentary reflects the author's perspective, based on existing literature and recent developments in digital health.

Results: Potential role: Personalised care in multimorbidity: DTs can simulate interactions between drugs and diseases. Decision support: Prediction of patient risk and response to treatment. Patient engagement: Sharing DT visualisations with patients regarding their health trajectory. Workflow and resource optimisation. Challenges to adaptation: Ethical concerns regarding patient privacy and risk of misuse of data. Increased clinician workload. Worsening health inequalities. Data integration: Most healthcare data remains fragmented. Computational costs.

Discussion: Current applications of DTs in healthcare: 3D DTs of heart are being used to facilitate simulation of arrhythmias, personalised ablation procedures, risk assessment, and recurrence prediction. DT models have been proposed that could prioritise patients requiring

urgent care, recommend treatment, and suggest optimal time to step down from critical care. DTs are being utilised in hospital workflow optimization to analyse patient flow and clinical demand patterns. DTs can be used in virtual clinical trials, resulting in accelerated drug development with minimal patient safety risk. They can forecast tumor growth and evolution, assisting clinicians in understanding disease trajectory.

Conclusion: DTs warrant revolutionary changes in healthcare. With their introduction in PC, they can help with management of multimorbidity and shared decision-making with patients. However, there are potential barriers complicating its adoption. Efforts are needed to establish feasible and adaptable models of DTs that can be safely incorporated into PC, for the benefit of PC workforce and patients.

ID 2111- CULTURAL COMPETENCE MATRIX IN HEALTHCARE FOR WORKING WITH SEXUAL AND GENDER MINORITIES: contributions to practice and professional training

Marco Túlio RIBEIRO [(1)] , Tatiana FIUZA [(2)], Rafael SOUSA [(1)], Daniel VIANA [(1)], Helena RIBEIRO [(3)], Maximiria BATISTA [(3)], Juliana SAMPAIO [(4)], Ivana BARRETO [(5)], Bruna LIMA [(1)], Micael SAMPAIO [(1)]

(1) Universidade Federal Do Ceará, Fortaleza, Brésil
(2) Universidade Federal Do Ceará, Fortaleza, Portugal
(3) Faculdade Chisthus, Fortaleza, Brésil
(4) Universidade Federal De Minas Gerais, Belo Horizonte, Brésil
(5) Fiocrz, Fortaleza, Brésil

Context: Sexual and gender minorities face higher health risks, worsened by discriminatory care and healthcare professionals' lack of cultural competence. The study developed and validated a Cultural Competence Matrix to guide including equitable healthcare practice.

Objectives: Describe aspects of a Cultural Competency Matrix in healthcare for working with Sexual and Gender Minorities and its contributions to professional practice and training.

Methods: he participatory study used the Nominal Group Technique to validate a cultural competency matrix for healthcare with Sexual and Gender Minorities. Six online groups with 21 participants—LGBTQIA+ users, experienced health professionals, and faculty—generated, discussed, and voted on ideas. The matrix was then revised and reformulated based on consensus and systematic analysis.

Results: The results consisted of the development of a cultural competency matrix composed of four domains, organized into knowledge, skills, and attitudes. The first domain addresses gender identities and sexual orientations, emphasizing core concepts, inclusive language, and respect for difference. The second focuses on the biopsychosocial aspects of LGBTQIA+ health, grounded in the Social Determination of Health and promoting non-reductionist clinical practice. The third domain concerns the professional–user relationship, highlighting nonviolent communication, welcoming practices, and the recognition and mitigation of biases. The fourth domain encompasses health care networks, support systems, and territory, reinforcing integral, intersectoral care and the defense of the rights of Sexual and Gender Minorities.

Discussion: The cultural competency matrix supports marginalized populations, strengthens collective health, and upholds the principles of Brazil's health system. It guides professional practice, informs training curricula, and fosters the education of sensitive, critical, and inclusive healthcare professionals.

Conclusion: The cultural competency matrix aims to train professionals who are culturally sensitive, open, and self-aware, going beyond technical skills. It emphasizes adaptability to cultural changes and fosters critical, flexible, and transformative practice.

ID 2007- La perception des personnes transgenres des consultations ou des soins avec des professionnel.le.s de santé

Aurelie JANCZEWSKI, Helene CARRIER, Solaine BREJON DE LAVERGNÉE, Melissa MARCOUX

Dumg Marseille, Marseille, France

Context: Les personnes transgenres ou en non-conformité de genre (incluant non binaire, genderfluid, agenre) sont sujettes à des discriminations entraînant un stress minoritaire lié au genre, des inégalités en matière de santé et des difficultés d'accès aux soins.

Objectives: L'objectif de l'étude était d'explorer les attentes et les besoins des personnes transgenres dans leur relation avec tous·tes les professionnel·les de santé, en recueillant leurs ressentis et vécus en situations de soins.

Methods: Une étude qualitative utilisant des entretiens individuels semi-dirigés a été menée auprès de 9 adultes transgenres. Le recrutement est passé par des associations LGBTQIA+ de la région XXX par mail, réseaux sociaux et contacts personnels. L'analyse des données a été basée sur une analyse thématique avec construction d'un modèle explicatif, inspirée de la phénoménologie interprétative. Une triangulation des données a été réalisée conjointement par les deux investigatrices.

Results: Les personnes transgenres rapportaient des difficultés d'accès aux soins dans un système de santé jugé discriminatoire et violent envers les minorités de genre. Pour surmonter ces freins aux consultations, les personnes transgenres élaboraient des stratégies d'adaptation, notamment le recours à l'automédication. Elles attendaient des professionnel·les de santé une prise en charge bienveillante et individualisée et un accueil adapté. Enfin, la formation de tous·tes les acteur·rices de la santé aux questions de santé des personnes transgenres semblait nécessaire pour améliorer leur santé et leur intégration dans le système de santé.

Discussion: Les critères COREQ ont été suivis. Le mode de recrutement via des associations LGBTQIA+ a pu sélectionner des personnes plus militantes . La grande majorité des participant·es vivaient en zone urbaine. La littérature retrouve des difficultés d'accès aux soins liées à un manque de professionnel·les formé·es et compétent·es, ainsi qu'un frein financier. Elle retrouve également des stratégies d'adaptation : réseaux de pairs et automédication. Enfin, la nécessité de formation apparaît dans la littérature internationale

Conclusion: Les personnes transgenres vivent dans une société et un système de santé où elles se sentent discriminées, touchées par les inégalités de santé et obligées de s'adapter. Une meilleure formation de tous·tes les professionnel·les de santé pour améliorer l'accueil et la qualité des soins est attendue par les personnes transgenres.

ID 1829- Consideration of gender stereotypes in the clinical practice of french military general practitioners — a qualitative thesis based on semi-structured interviews

Pierre-Michel BAUDOUIN, Hélène VANQUAETHEM

Service De Santé Des Armées, Paris, France

Context: Gender is a key determinant of health equity, yet gender stereotypes are still inconsistently considered in clinical reasoning. In military primary care, general practitioners also perform fitness-for-duty assessments and advise command, which may increase the impact of gendered expectations on decision-making.

Objectives: To explore how military general practitioners perceive the influence of gender stereotypes on clinical practice and occupational/aptitude decisions, and to describe the strategies they use to manage this influence.

Methods: Qualitative study using semi-structured interviews with active-duty military general practitioners from different service branches. Participants were purposively recruited to maximize diversity (age, gender, populations served). Interviews were audio-recorded, transcribed and anonymised, then analysed using grounded theory with open and axial coding. Themes were synthesised and used to build a typology of physician profiles.

Results: Twenty-one interviews were analysed. Three main axes emerged: (1) gender sensitivity, (2) clinical fields perceived as influenced by stereotypes, and (3) management strategies. Understanding of the sex/gender distinction was uneven and rarely mobilised explicitly. Stereotypes were framed either as biased generalisations to avoid or as pragmatic reference points. Reported affected fields included sports-related injuries, mental health, sexual health, and fitness-for-duty assessments. Management strategies were mostly individual (standardised templates, deliberate questioning, case-by-case adaptation), with limited collective or institutional support. Five physician profiles were identified; gender sensitivity did not consistently predict whether participants spontaneously recognised stereotype-related influences.

Discussion: Gender stereotypes may shape both care and occupational decisions, but recognition often requires a context that encourages reflexivity. Reliance on individual vigilance can lead to variable practices and uneven equity. Institutional training, structured clinical tools, and peer-reflection spaces could help translate awareness into routine practice.

Conclusion: Gender stereotypes influence military general practice across several clinical domains. Embedding reflexivity and gender competence into training and organisational routines may reduce variability and support more equitable care and assessments.

ID 1221- Transgender individuals Expectations of their General Practitioners in XXX: A Scoping Review

Axel DESCAMPS

Lille University, Lille, France

Context: In XXX, an increasing number of individuals identify as transgender, and related health needs are rising. In 2023, the World Professional Association for Transgender Health (WPATH) recommended that primary care professionals, particularly general practitioners (GPs), address these needs. In XXX, GPs play an increasingly central role in transgender healthcare, yet evidence in this area remains scarce. While WPATH outlines health objectives identified by medical professionals, the expectations of transgender people toward GPs remain insufficiently documented, and no review has addressed this to date.

Objectives: The primary objective of this study was to identify, in the scientific literature, the expectations of transgender adults toward their GPs in XXX. The secondary objective was to provide an overview of the current state of research in this field

Methods: A scoping review was conducted by one investigator using PubMed, Cairn, SUDOC, Google Scholar, PsycINFO, LiSSa, and Cochrane. The main MeSH terms used were “primary care,” “general practice,” “transgender,” and “transsexualism.” All studies published before 01/08/2023 were included. Literature reviews and other non-primary sources were excluded. Extracted data were synthesized thematically and included: expectations of transgender individuals toward their GP, study type, study quality (STROBE/SRQR), and publication status.

Results: Expectations fell into two categories: “general,” applicable to any patient population, and “specific,” related to transgender health needs. These aligned with core GP competencies. The most frequent were: relational and communication skills (comforting environment, active listening, absence of misgendering), assistance with administrative procedures for long-term condition status, management of hormone therapy, guidance through the care pathway, facilitation of access to healthcare, and ongoing GP training. Primary care research on this topic is substantial but lacks published data and quantification of the relative importance of these expectations.

Discussion: This study is novel in exploring grey literature within French primary care and follows PRISMA-ScR guidelines (22/22), with findings comparable to international studies. Potential selection bias due to a single reviewer and the lack of a dedicated MeSH term for transgender identities was mitigated through multiple search strategies.

Conclusion: Transgender patients express realistic expectations aligned with GP competencies, and

this review clarifies these expectations while underscoring the need for further quantitative research.

ID 719- Rural Realities in Primary Care: Insights from Older Sexual and/or Gender Minority Adults and Clinicians. A qualitative study

Amel BAGHDADLI [(1)] , Aria JALILI [(1)], Élaine LAVOIE [(1)], Maria Vanessa SERRANO BORRAZ [(1)], Sophie LAUZIER [(2)], Kevin LAVOIE [(2)], Andy CYR [(3)]

(1) Université Laval, Trois-Pistoles, Canada
(2) Centre Hospitalier Universitaire (chu) De Québec-Université Laval Research Center, Quebec,, Québec, Canada
(3) Université Laval, Rimouski, Canada

Context: The number of sexual and/or gender minority (SGM) adults in Canada is rising, including among seniors. Many continue to face health inequities such as stigma in care, limited support, unmet health needs, and lasting reluctance to seek help after previous negative experiences. Most available evidence comes from urban settings, leaving little understanding of rural contexts, where reduced anonymity and scarce inclusive services may strongly shape how SGM older adults engage with primary care.

Objectives: (1) To describe how rural SGM older adults experience consultations with family doctors and (2) to examine how rural family physicians and other primary healthcare providers perceive the care they provide.

Methods: This qualitative descriptive study, approved by a Research Ethics Board, draws on Minority Stress Theory and Bradshaw's model of need. Semi-structured interviews were conducted with rural SGM adults aged ≥65 (n=15) and with rural family physicians and other healthcare providers (n=12). An inductive–deductive thematic approach informed the analysis.

Results: Four themes emerged from the initial interviews. Managing identity in small communities: several participants adjusted or withheld parts of their identity to avoid stigma or unwanted attention. Recognition in clinical encounters: experiences ranged from subtle affirmation to feeling unseen or misidentified, often due to inconsistent documentation of names or pronouns and a gap between clinical neutrality and patients' sense of erasure. Structural barriers: clinicians reported limited SGM-specific tools and training, while patients avoided certain services out of fear of being recognized in their community. Relational strengths: continuity and long-standing relationships helped build trust and, when present, allowed for more open communication, with clinicians noting that some patients shared aspects of their identity for the first time in this safe relational context

Discussion: Preliminary insights suggest that rurality intensifies identity-management pressures and that well-intentioned neutrality can inadvertently reinforce feelings of invisibility. Limited resources and visibility concern further hinder access to affirming care, although strong continuity can help counterbalance these challenges.

Conclusion: By bringing forward voices rarely heard in small-community health research, this study points to the need for rural-adapted strategies while drawing on the relational strengths of close-knit communities to enhance identity-affirming primary care for SGM older adults.

Gender

ID 675- Sexual orientation and gender: General practitioners' comfort in addressing these topics during consultations and their level of knowledge.

Orientation sexuelle et genre : aisance de l'abord en consultation et connaissances des médecins généralistes,

Jessica GUELFF (1) , Ermelinda RRONJA (2), Wonnick SON (2)

(1) Univ Angers, Pops, Sfr Icat, F-49000 Angers, France, Angers, France, (2) Univ Angers, 49000 Angers, France, Angers, France

(2)

Context: Lesbian, gay, bisexual, transgender, queer and intersex (LGBTQI) individuals are at increased

risk of mental health issues, substance abuse, sexually transmitted infections, discrimination and suicide attempts. For general practitioners (GP), these topics are difficult to address, even though a better understanding of patients' status could improve prevention, screening and therapeutic alliance.

Objectives: To assess the GPs' ease of discussing sexual orientation and gender during consultations. Secondary objectives focused on knowledge of health specificities of LGBTQI+ patients and training.

Methods: Descriptive study using an anonymous online questionnaire distributed in 2025 to GPs and interns in XXXX. The primary endpoint was the level of comfort in addressing sexual orientation and gender issues. The questionnaire explored seven themes. A descriptive and then comparative analysis was performed based on the level of comfort. The study was validated by an ethics committee.

Results: The average age of 305 respondents was 36, with 68.9% being women. The level of ease in addressing sexual orientation and gender issues during consultations was moderate (5.35/10), significantly higher among doctors who had received specific training ($p < 0.001$). The majority reported knowing the definitions of sexual orientations (81.3%). 81.6% had received no initial or continuing training, and 77.7% wanted it. The majority had not noted the increased risk of chronic diseases in these patients. The frequency with which sexual orientation was discussed was significantly correlated with the level of comfort, specific training and professional status ($p < 0.001$).

Discussion: The results, in line with the literature, highlight the need to develop specific training to improve the reception and care of these patients. GPs could thus take care of the patient as a whole, better understand their health issues and improve their practices. However, addressing sexual orientation is not a recent issue and difficulties persist over time, even though many guides and tools already exist to help healthcare professionals. Qualitative studies would be useful to explore these barriers.

Conclusion: GPs report an average level of ease when discussing patients' sexual orientation during consultations, despite the existence of numerous guides and tools. It would be interesting to explore the persistent barriers to discussion during consultations.

ID 149- Factors influencing primary care clinicians' self-efficacy and delivery of gender-affirming care: a mixed-methods study in Montérégie, Québec

Judith LAJEUNESSE, Antoine ROGER, Michelle DEAKIN

Université De Sherbrooke, Longueuil, Canada

Context: Family physicians, nurse practitioners, and residents increasingly encounter patients experiencing gender incongruence or questioning their gender identity. Yet few provide gender-affirming care directly, often referring patients to tertiary centers. In Québec, long waiting times—up to two years in expertise centers—delay essential interventions that protect mental health. Concentrating such care in tertiary settings reinforces a pathologizing view of gender diversity and leaves primary care teams uncertain about their competencies. Despite the growing importance of gender-affirming services, data on clinicians' self-efficacy remain scarce, particularly in Canada and Québec. This study addresses this gap by examining factors influencing self-efficacy and the provision of gender-affirming care within community and university-affiliated primary care settings.

Objectives: To identify factors influencing primary care clinicians' self-efficacy and delivery of gender-affirming care through four aims: (1) describe clinicians' self-efficacy across care dimensions; (2) identify personal, professional, and organizational factors associated with higher self-efficacy; (3) explore perceived barriers and facilitators; and (4) generate recommendations to improve training, support, and care organization.

Methods: Following Creswell and Plano Clark's (2018) framework, a sequential explanatory mixed-methods design (QUAN→QUAL) is being implemented. Data collection is now underway among family physicians, nurse practitioners, and

residents working in public and university-affiliated family medicine groups (GMF/GMF-U). The quantitative phase uses a structured online questionnaire assessing general self-efficacy with the General Self-Efficacy Scale (Schwarzer & Jerusalem, 1995), perceived competence in gender-affirming care, and perceived barriers and facilitators. Descriptive and inferential analyses (correlation and multiple regression) will identify associations between self-efficacy and contextual variables. The qualitative phase includes semi-structured interviews to deepen understanding of modifiable mechanisms. Ethical approval has been obtained from the Research Ethics Committee of the CISSS de la Montérégie-Centre.

Results: Preliminary analyses suggest overall low self-efficacy among clinicians, with higher confidence associated with prior exposure to transgender and gender-diverse patients, targeted training, and supportive clinical environments.

Discussion: These early trends highlight the need to strengthen training, sustained exposure, and organizational support in academic primary care to better serve transgender and gender-diverse patients.

Conclusion: This study will provide actionable, evidence-informed recommendations to enhance education and system design, supporting more humanistic, equitable, and accessible gender-affirming care.

ID 1892- Healthy aging centers (YAŞAM) in Türkiye: a primary care–focused, comprehensive healthcare model for individuals aged 80 years and over.

Izem ZEYBEKOGLU, Yasemin ÖZKAYA, Nurdan TEKGÜL

University Of Health Science İzmir City Hospital, Izmir, Türkiye

Context: Global life expectancy has reached 73.5 years, and the population aged 80 years and over is projected to triple by 2050, reaching 426 million. Population aging is associated with multimorbidity, functional decline, cognitive impairment, frailty, and increased social care needs. Therefore, accessible and continuous healthcare models for older adults are essential. In response, XXX launched the Healthy Aging Centers (XXX) in 2023 as an innovative healthcare service model for individuals aged 80 years and over. This study aims to introduce the XXX outpatient clinic model, and emphasize the role of primary healthcare and family medicine in supporting healthy aging through screening, follow-up, and risk assessment.

Methods: XXX outpatient clinics operate within Ministry of Health–affiliated facilities and provide comprehensive medical, functional, and psychosocial assessments. Care is delivered by multidisciplinary teams including a geriatrician (if available), a family physician or internist, a nurse, and elderly care staff, with additional professionals involved as needed. Assessments are conducted in outpatient clinics, at home, or via telehealth, addressing frailty, fall risk, nutrition, cognition, depression, medication use, and chronic diseases.

Originality: Before the establishment of XXX outpatient clinics, similar initiatives in XXX were fragmented, lacked a strong clinical identity, and were not primarily lifestyle-oriented. The XXX model represents a novel organizational approach addressing this gap.

Lessons learned and future implication: XXX clinics have improved quality of life through early diagnosis and continuous follow-up. However, limited staffing and inadequate technological infrastructure currently restrict coverage and telehealth effectiveness. Expanding human resources and stren

Discussion: From a family medicine perspective, early diagnosis of chronic diseases, monitoring of polypharmacy, assessment of frailty and fall risk, and screening for malnutrition, cognitive decline,

and depression are essential components of healthy aging. XXX outpatient clinics support early risk detection and strengthen preventive care services.

Conclusion: The XXX outpatient clinic model provides an accessible, integrated, primary care–based health service for older individuals in XXX. Aligned with the holistic principles of family medicine, it supports healthy aging and equitable access to healthcare, promotes independence, and improves care coordination within the healthcare system. Keywords: Frail Elderly, Healthy Ageing, Health Equity, Preventive Care, Primary Health Care

ID 1883- The challenge of home care patients' loneliness: how can it be addressed in rural primary care?

Nuria PARRA-MACIAS, Marta CARABASA-SERRA, Esperança LLOVER-BOSCH, Nicole Alejandra HERNANDEZ-RIVERA, Rafael Antonio SANCHEZ-COUTO, Ana Belen FERNANDEZ-GUERRA, Vishal SHAHANI-SHAHANI

Fundació Salut Empordà-Abs L'escala, L'escala, Espagne

Context: Rural primary care faces a growing burden of unwanted loneliness in an ageing population, especially among home-care patients with multimorbidity and functional dependency. Loneliness is linked to higher mortality, depression, cognitive decline and service use, making it a key target for community-based, low-intensity interventions that can complement overstretched health services.

Methods: In a rural basic health area in XXX, a peer-to-peer companionship programme has been implemented within the home-care service since 2025. Non-professional peers with similar lived experiences offer emotional support, active listening and practical help to home-care patients reporting unwanted loneliness, following four phases: structured training, matching of peers and users, regular telephone or digital contacts, and monitoring by the primary care team. The programme is grounded in principles of empowerment, recovery, horizontality and community participation, aligning with European evidence on peer support and group-based psychosocial interventions for loneliness.

Originality: Unlike most European initiatives, which rely mainly on volunteers or group activities, this programme integrates trained peers with lived experience directly into rural home-care pathways. It positions peer support as a core element of the care plan for h

Lessons learned and future implication: Early experience suggests positive impact on both recipients and peers, with perceived improvements in emotional wellbeing, reduced social isolation and the creation of informal support networks. The structured training and careful matching process are cr

Discussion: International evidence indicates that peer-based and psychosocial group interventions can reduce loneliness and depressive symptoms in older adults, especially when embedded in primary care and community networks. However, these programmes are sensitive to organisational support, supervision and role clarity; without adequate integration into multidisciplinary teams, their potential for improving mental health and system efficiency is diminished.

Conclusion: A rural peer-to-peer companionship model for unwanted loneliness in home-care patients appears feasible, acceptable and potentially scalable to other regions and conditions, provided that training, coordination and evaluation are ensured.

Corresponding author: Nuria Parra-Macias, nuriaparramacias@gmail.com

ID 1879- Building block therapy in the primary rural approach to home care patients' loneliness

Nuria PARRA-MACIAS, Marta CARABASA-SERRA, Esperança LLOVER-BOSCH, Nicole Alejandra HERNANDEZ-RIVERA, Rafael Antonio SANCHEZ-

COUTO, Ana Belen FERNANDEZ-GUERRA, Vishal SHAHANI-SHAHANI

Fundació Salut Empordà-Abs L'escala, L'escala, Espagne

Context: Loneliness is highly prevalent among home care patients and is associated with worse physical and mental health outcomes, increased healthcare utilization and higher mortality risk. In a rural primary care centre in XXX, around 80% of the home care population report unwanted loneliness, adding emotional and social complexity to already fragile clinical situations. There is a need for innovative, low-cost, relationship-centred interventions that can be integrated into routine domiciliary care.

Methods: We structured construction-block therapy programme for home care patients who explicitly expressed loneliness. Sessions are guided by life-story headings (identity, childhood and youth, favourite places, memorable anecdotes, future plans), using construction bricks as symbolic and metaphorical tools to build personal narratives. The facilitator poses sequential challenges, individually or in small groups, and patients respond by creating models that serve as anchors for emotional expression, active listening and practical problem-solving around social support.

Originality: While positive psychology-based LEGO therapy has been described mainly in children with autism, its use in older, frail adults with loneliness is almost unexplored. This rural experience adapts a highly structured, gamified narrative method to domiciliary

Lessons learned and future implication: Construction-block therapy facilitates emotional disclosure, improves perceived social connection and helps patients reformulate negative internal narratives into more hopeful life stories. Collaborative building fosters a sense of belonging and supports

Discussion: Narrative-based positive psychological interventions are promising for loneliness, but evidence in adults and in rural contexts remains limited and methodologically heterogeneous. This experience suggests that structured, story-centred brick therapy can operationalise key mechanisms of loneliness interventions within routine primary care home visits.

Conclusion: A rural, home-based construction-block therapy model appears to be a scalable, context-adaptable approach to address unwanted loneliness among frail home care patients, enhancing emotional wellbeing, social connection and personal meaning.

Corresponding author: Nuria Parra-Macias, nuriaparramacias@gmail.com

ID 1623- The challenge of advanced frailty: how can it be addressed in rural primary care?

Nuria PARRA-MACIAS, Marta CARABASA-SERRA, Esperança LLOVER-BOSCH, Nicole Alejandra HERNANDEZ-RIVERA, Rafael Antonio SANCHEZ-COUTO, Ana Belen FERNANDEZ-GUERRA, Vishal SHAHANI-SHAHANI

Fundació Salut Empordà-Abs L'escala, L'escala, Espagne

Context: Primary health care must undergo a transformation to address population ageing and remain sustainable. Population ageing entails more complex health problems, which must be faced with fewer professionals and resources. This makes it necessary to seek new care models.

Methods: We present an innovative, frailty-focused basic care unit (BCU) in a rural area of XXX, with 700 patients (100 of them receiving home care) accounting for one fifth of the centre's visits but responsible for 70% of the pharmacy budget. The unit is integrated and self-managed by two nurses, a case manager, a family physician, an internist and an administrative officer, coordinated with a social worker, a clinical psychologist and a social one, a physiotherapist, an occupational therapist and a dietitian, the palliative care team, an intermediate-care geriatrician and a hospital-at-home service.

Originality: In Europe, chronic care management models are predominantly based on the Chronic Care Model and on integrated care programmes for multimorbidity, with interventions such as risk stratification, clinical pathways, multiprofessional teams and growing use of

Lessons learned and future implication: This BCU makes it possible to provide comprehensive,

proactive, patient-centred care tailored to the needs of an ageing rural population, improving quality of life, reducing polypharmacy, decreasing the burden on the health system and improving the unit c

Discussion: Despite sub-specialisation in frailty care, there are significant differences between patients requiring hospital-level care at home and the rest of the BCU caseload, such as high multimorbidity, risk of institutionalisation and a high dependency burden. International experience suggests that specialised home-based services reduce hospital days and readmissions, but are highly sensitive to organisation, staffing and professional skill mix; without this sub-specialisation, the potential for efficiency and sustainability of the overall model is weakened, so it must be considered in the immediate future.

Conclusion: This is a scalable solution for other health regions that offers answers to the threefold complexity (clinical, social and system-level) posed by these patients.

ID 159- Cognitive Red Flags in SAGE Test: Early Predictors of Cognitive Decline in Primary Care

Ana Maria GARCIA-RODRIGUEZ [1] , Miguel Jose SANCHEZ-VELASCO [2], Rebeca HERNANDEZ-ROMAN [1], Cristina FANARRAGA-VERGEL [1], Pablo GONZALEZ-GARCINUÑO [1], Irene ASENJO-CABRERO [1], Beatriz REJAS-DE CASTRO [1], Javier RODRIGUEZ-PEREZ [1], Rebeca VEGA-GUTIE

(1) Cs Plaza Del Ejercito Gerencia Atencion Primaria Valladolid Oeste, Valladolid, Espagne
(2) Gerencia Regional De Salud De Castilla Y Leon, Valladolid, Espagne

Context: Early detection of cognitive decline is crucial for timely intervention and prevention. Even in individuals with normal global cognitive performance, subtle domain-specific deficits may serve as “red flags” (RF) that predict future cognitive impairment. This study analyzes the presence of such red flags in cognitively normal individuals, their association with sociodemographic and clinical variables, and their potential predictive value for different dementia profiles.

Objectives: To identify early cognitive alterations in patients with normal total SAGE scores (≥17); to evaluate their relationship with age, sex, education, and COVID-19 history; and to explore possible cognitive profiles (Alzheimer’s, vascular, Lewy body) associated with specific patterns of red flags.

Methods: A cross-sectional observational study was conducted between 2024–2025 at XXXXXX. The Self-Administered Gerocognitive Examination (SAGE) was administered to 380 participants aged ≥14 years. Cases with scores ≥17 but with ≥2 altered sensitive items (memory, clock drawing, money, sequence, triangles) were classified as red-flag positive. Sociodemographic data, COVID-19 history, depression, and functional status (ABVD) were recorded. Statistical analyses included chi-square, t-tests, relative risk (RR), and odds ratios (OR), with $p<0.05$ considered significant.

Results: Red flags were identified in 84 participants (28.7%) despite normal SAGE scores. RF prevalence increased with age (40.5% in 60–79 years) and was twice as high in participants with primary education compared to those with university studies (RR=2.1–2.25; $p<0.001$). The most affected items were clock drawing, immediate memory, and visuospatial reasoning. Among those <60 years, 42.9% presented at least one RF: 66.7% with memory deficits (suggestive of early Alzheimer’s), 21.1% with executive dysfunction (vascular profile), and 12.2% with visuospatial impairment (Lewy body profile). COVID-19 history showed no significant association. Functional and depressive symptoms were more frequent in red-flag positive cases.

Discussion: Cognitive red flags reveal early domain-specific deficits that may precede global decline. Education emerged as the strongest protective factor, supporting the role of cognitive reserve. The SAGE test’s item-level analysis enhances sensitivity for early detection in Primary Care.

Conclusion: Red flags in cognitively normal individuals may identify prodromal cognitive decline. Their systematic detection and follow-up in Primary Care could improve early diagnosis, guide tailored interventions, and reduce future clinical and social burden.

ID 55- Weekly capillary INR monitoring reduces VKA-related iatrogenesis in elderly nursing home residents: a cluster randomized trial

Chloé SIKIRDJI [(1)] , David COSTA [(2)], Murielle GLONDU-LASSIS [(3)], Hermine SAGUY [(4)], Anne-Sophie ODOUL [(5)], Mélanie BADIN [(1)]

(1) Faculté De Médecine De Montpellier-Nîmes, Vergèze, France
(2) Faculté De Médecine De Montpellier-Nîmes, Nîmes, France
(3) Faculté De Médecine De Montpellier-Nîmes, Saint Bauzille De Putois, France
(4) Faculté De Médecine De Montpellier-Nîmes, Cabestany, France
(5) Faculté De Médecine De Montpellier-Nîmes, Montpellier, France

Context: Vitamin K antagonists (VKA) have a narrow therapeutic margin and are associated with a high risk of iatrogenic complications. In nursing homes, 13% of patients are treated with VKAs, often with a time in therapeutic range (TTR) below the recommended 65%. International Normalised Ratio (INR) measured by capillary puncture allows more frequent assessment than venous sampling.

Objectives: To compare the difference in TTR and number of venous and haemorrhagic events between INR monitoring by weekly capillary (INRc) testing versus monthly venous (INRv) testing.

Methods: This prospective, superiority, cluster-randomised study recruited patients living in French nursing homes treated with VKA for > 6 months with a target INR range of 2.5 [2-3] or 3 [2.5-3.5]. Exclusion criteria were life expectancy < 1 month and Karnofky index ≤ 20%. Nursing homes were randomised to control group (monthly INRv) or intervention group (weekly INRc). The primary outcome was TTR, calculated using Rosendaal's method and compared using mixed linear regression. Patients were recruited from November 2022 to November 2023 and followed for 6 months.

Results: Fifteen nursing homes were randomised: nine in the intervention group (26 residents, 429 venous INR measurements) and seven in the control group (19 residents, 226 venous INR measurements). The sample size was not reached due to recruitment difficulties during the Covid-19 pandemic. The TTR increased by 25%, (95% CI :[5.1; 45], $p < 0.05$), with capillary monitoring. No major bleeding or thrombotic events and no hospitalisations were reported. There is no difference based on age (under or over 90 years). The intracluster correlation coefficient between INRv and INRcap is excellent at 0.89 [0.84; 0.92].

Discussion: Few studies in primary care focus exclusively on frail, dependent older adults, despite their higher risk of iatrogenic harm. Despite not reaching the anticipated sample size, the increase in TTR was statistically significant with INRc. The TTR with the weekly monitoring was 68%, exceeding the level of 65% recommended by NICE Guideline.

Conclusion: Weekly INRc monitoring improves anticoagulation control and reduces the risk of VKA-related iatrogenic events in elderly nursing home residents.

Good prescribing

ID 1944- Efficacy and safety of topical diclofenac in the treatment of knee osteoarthritis: a systematic review and meta-analysis

Thibault MENINI

Clermont Auvergne University, Clermont-Ferrand, France

Context: Knee osteoarthritis is a common condition that causes debilitating pain. The painkillers and anti-inflammatory drugs commonly used orally can cause serious side effects. In order to limit these, clinical practice guidelines describe topical non-steroidal anti-inflammatory drugs as an attractive first-line option. Among the molecules available, diclofenac is the most commonly prescribed.

Objectives: The objective of our study is to evaluate the efficacy and safety of topical diclofenac in the treatment of knee osteoarthritis.

Methods: We conducted a systematic review in the Cochrane, PubMed, and Embase databases, with a meta-analysis of randomized controlled trials (RCTs) evaluating the efficacy and safety of topical diclofenac versus placebo in knee osteoarthritis. The risk of bias was assessed using the RoB2 tool. The outcomes of the selected RCTs were meta-analyzed using RevMan software, and their level of evidence was assessed using the Rebuild the Evidence Based (REB) method.

Results: Of the 2,463 articles identified, 13 RCTs were included, eight of which had a low risk of bias and from which data were extracted. The primary outcome measures (POMs) meta-analyzed were pain assessment and functional disability at 12 weeks of treatment according to the subscales of the Western Ontario and McMaster Universities Osteoarthritis Index. Diclofenac was statistically superior to placebo, with a standardized mean difference respectively of -1.49 [-2.14, -0.83] (95% CI), p<0.01 and -4.98 [-7.15, -2.80] (95% CI), p<0.01. For these two POMs, the REB method concluded that there was “strong evidence.” Secondarily, safety was analyzed, showing no significant difference in the overall occurrence of adverse effects. Subgroup analysis shows more frequent skin dryness in the diclofenac group and less frequent erythema.

Discussion: These results are consistent with those found in the literature. This work enabled the evidence to be graded according to the REB method.

Conclusion: This systematic review and meta-analysis showed superiority at 12 weeks of treatment with topical diclofenac compared to placebo in relieving pain and functional impairment in knee osteoarthritis, with a high level of evidence and no serious adverse effects.

ID 1807- Misuse of pain medication in primary care

Frédéric FORTIN [(1)] , Catherine LAPORTE [(1)], Céline LAMBERT [(2)]

(1) Département De Médecine Générale, Clermont-Ferrand, France
(2) Chu, Clermont-Ferrand, France

Context: In 2015, France was the third largest consumer of analgesics in Europe and the largest consumer of paracetamol. In France, 43% of reasons for consulting a general practitioner are related to pain and 57% of patients consulting a general practitioner received a prescription for analgesics.

Objectives: Determine the prevalence of qualitative misuse of analgesic treatments in patients followed up in general practice at least once during the past year. The secondary objectives were to determine which drug classes were affected and the reasons for misuse.

Methods: Nationwide, multicentre cross-sectional study of a population of adult patients who consulted their general practitioner at least once during the inclusion period. Recruitment was carried out in general medical offices throughout France between January 2022 and June 2022. Data was collected using a self-administered questionnaire.

Results: A total of 910 participants were recruited, 639 (70%) of whom were women, with an average age of 53 (± 18). Among them, 98 (11%) were identified as having misused at least one analgesic treatment. There was a correlation between analgesic misuse and lower educational achievement. The five most commonly used classes of drugs were, in descending order, paracetamol, non-steroidal anti-inflammatory drugs (NSAIDs), codeine, tramadol and opium. Among the most commonly used classes of drugs, patients mainly misused antidepressants (48%), followed by tramadol (18%), opium (16%), morphine (13%) and codeine (11%). Finally, the main reasons given were ‘to feel better’ (55%), ‘to sleep’ (39%) and ‘to relax/counter stress’ (25%).

Discussion: The strength of this study lies in its original approach, as it focuses on primary care and was conducted directly in general practitioners' offices. In order to limit recall bias and facilitate the identification of medications containing analgesics, the analgesic treatments studied were listed under

their various trade names. The representativeness of the sample is questionable, as only patients who were able to visit a general practitioner could be included. The 31 patients excluded from the study due to missing data are not comparable to the 910 patients in terms of age and professional status. The existence of social desirability and memory bias when completing the self-administered questionnaire cannot be excluded.

Conclusion: It appears difficult to target a population at risk of misuse in primary care, encouraging the systematisation of prevention messages before introducing or dispensing pain relief treatment and taking the time to assess their personal use.

ID 37- Appropriate Antibiotic Use: A Lever for Sustainable Healthcare

Nutte LOUISE [(1)], Louise NUTTE [(2)] , Marie-Anne BOULDOUYRE [(3)], Florence STORDEUR [(3)], Samy TAHA [(4)], Caroline GREGOIRE [(4)]

(1) Maison De Santé Pluriprofessionnelle Pôle Santé Vanvéen, Vanves, France
(2) Maison De Santé Pluriprofessionnelle "pôle Santé Vanvéen", Centre Régional En Antibiothérapie Idf, Vanves, France
(3) Centre Régional En Antibiothérapie Idf, Paris, France
(4) Centre Régional En Antibiothérapie Idf; Institut Pasteur, Paris, France

Context: Antimicrobial resistance is a growing threat to global public health. It is central to the “One Health” concept, connecting human, animal, and environmental health. In XXX, action plans have been implemented to promote the appropriate use of antibiotics and curb the rise of bacterial resistance. At the same time, eco-prescribing is emerging as a new public health priority in response to the environmental crisis. XXX, the fourth highest antibiotic-prescribing country in XXX, is estimated to deliver nearly 50% unnecessary or inappropriate antibiotic prescriptions. General practitioners, who issue around 80% of all antibiotic prescriptions, stand at the center of this dual challenge.

Methods: The principles of appropriate antibiotic use and eco-prescribing were compared. Both approaches share a common logic: prescribing less and prescribing better to protect public health and the environment. Appropriate antibiotic use is structured around five principles: correct indication, correct drug, correct dosage, correct duration, and reassessment. Eco-prescribing relies on three pillars: prescribing less, prescribing better, and reducing the environmental impact of prescriptions. The first two overlap with appropriate antibiotic use. Several simple strategies can reduce environmental impact: prioritizing the oral route, reducing packaging, and shortening treatment durations. Different scores assess the environmental impact of medications, including the PBT score (persistence, bioaccumulation, toxicity) and the CO_2 emission score. These indicators may diverge: for example, among fluoroquinolones, ofloxacin emits 28% less CO_2 than levofloxacin but has a higher PBT index.

Originality: Embedding eco-prescribing within antibiotic stewardship strategies constitutes a novel and forward-looking approach, particularly rarely examined in primary care.

Lessons learned and future implication: The environmental impact of antibiotics goes beyond existing scoring systems and must also account for their effects on the microbiota and on antimicrobial resistance. These limitations highlight the need to develop antibiotic-specific indicators that int

Discussion: Beyond measurement tools, reducing unnecessary prescriptions remains the most effective lever. Eco-prescribing offers an additional lever and may enhance general practitioners’ awareness of appropriate antibiotic use by emphasizing its major environmental dimension.

Conclusion: Prescribing less and prescribing better. Through their shared co-benefits, these two major public health challenges reinforce one another and provide strong motivation for healthcare professionals.

ID 978- Declarative antibiotics prescription and management of male urinary tract infections in France: a national survey of

general practitioners using computer-generated clinical vignettes

Benjamin SOUDAIS [1] , André GILLIBERT [2], Pauline ROUPPERT [3], Julien POIMBEUF [4]

(1) Department Of General Practice, Rouen, France
(2) Chu Rouen, Rouen, France
(3) Locum Gp, Rennes, France
(4) Sos Medecin, Rennes, France

Context: General practitioners (GPs) consider male urinary tract infections (mUTIs) to be diagnostically challenging.

Objectives: This study sought to identify factors associated with declared antibiotic prescribing intentions by French GPs for the management of mUTIs.

Methods: A national observational practice survey was conducted using an online questionnaire comprising five randomly generated clinical vignettes presenting urinary symptoms in men. GPs indicated their prescribing intentions and diagnostic approach. The primary outcome was declared antibiotic prescribing intent (immediate, delayed, or none). Secondary outcomes included declared performance of digital rectal examination (DRE), urine dipstick testing, and requests for full blood count (FBC), prostate-specific antigen (PSA) testing, or urinary tract/prostate ultrasound. Descriptive analysis was performed and multivariable linear models were used to identify factors associated with antibiotic prescribing.

Results: Of 2,202 vignettes analysed (515 GPs), immediate antibiotic therapy was declared for 45.5%, delayed prescription for 36.3%, and no antibiotics for 18.1%. Intrinsic factors independently associated with immediate antibiotic prescribing were fever and burning on urination, followed by low-grade fever, urinary frequency, haematuria, and pelvic pain. The only extrinsic factor was a history of immunosuppression. Declared investigation rates were high: urine culture (96.6%), dipstick testing (61.4%), and PSA testing (21.2%). Fever positively influenced FBC requests, whilst burning on urination showed inverse association. Low-grade fever or burning on urination were associated with reduced ultrasound ordering. Antibiotic choice was predominantly (68%) a 14-day fluoroquinolone regimen, with levofloxacin most commonly prescribed.

Discussion: Declared investigation rates substantially overestimated actual practice reported in the literature, suggesting a gap between intentions and real-world behaviour. PSA testing, though lacking guideline support, was requested in selected cases. GPs consistently declared prescribing fluoroquinolones regardless of infection severity, aligning with French Infectious Diseases Society (SPILF) therapeutic guidelines but conflicting with French National Agency for Medicines and Health Products Safety (ANSM) warnings. A small minority declared prescribing fluoroquinolone-sparing agents such as nitrofurantoin or pivmecillinam, contrary to current recommendations.

Conclusion: Fever and burning on urination are the main determinants of immediate antibiotic prescribing for mUTIs. Updated French guidelines are anticipated in 2026, based on Northern European countries' fluoroquinolone-sparing approaches, aiming to reduce broad-spectrum antibiotic consumption whilst maintaining therapeutic efficacy.

ID 787- Analysis of antibiotic prescriptions for Lyme borreliosis by French general practitioners between 2012 and 2022

Pierre-André GREMILLON, Steve LANDRY NGUALA, Pauline ARIAS, Alice RAFFETIN

Centre Hospitalier Intercommunal De Villeneuve-Saint-Georges, Villeneuve-Saint-Georges, France

Context: With the increasing incidence of Lyme borreliosis (LB) in France and its growing media coverage, general practitioners (GPs) are encountering this disease more frequently. They also face a complex infection that presents diagnostic and therapeutic challenges.

Objectives: This study aimed to analyze the antibiotic prescriptions issued by French GPs for LB and to compare them with existing recommendations.

Methods: We conducted an observational, retrospective practice-based study using the THIN Cegedim database, covering the period from 2012 to 2022. The study was divided into three periods: 2012–2018 (T1), 2018–2019 (T2), and 2019–2022 (T3), in order to compare the evolution of prescriptions with the guidelines in force. Each prescription received a quality score (score 1: correct antibiotic chosen, but errors in dosage and duration; score 2: correct antibiotic, with either dosage or duration incorrect; score 3: correct antibiotic choice with correct dosage and duration).

Results: In total, 8,408 patients and 3,010 GPs from the 13 French regions were included. We identified 9,802 cases of erythema migrans (97.6%), 230 cases of Lyme arthritis (2.2%), and 11 cases of neuroborreliosis (0.1%). GPs prescribed the correct antibiotic in most cases (88.97% of prescriptions with an appropriate antibiotic). For erythema migrans, the quality of prescriptions rated as score 1 improved over time (T1: 14.8%; T2: 17.4%; T3: 37.7%; p=0.02), there was a slight increase in score 2 (T1: 35.9%; T2: 44.1%; T3: 38.2%; p=0.06), and a decrease in score 3 (T1: 38.2%; T2: 25.6%; T3: 13.4%; p=0.017). The study period was associated with poorer selection of treatment duration by GPs (p<0.001). The patient's age and sex, as well as the region where the GPs practiced, were not associated with prescription quality.

Discussion: While GPs often prescribe the correct antibiotic, they face challenges regarding dosage and particularly treatment duration. This could be explained by the time required to implement a recommendation in routine care, as evidenced by the longer duration of period 1 of our study compared to periods 2 and 3.

Conclusion: Targeted prescribing support tools for LB could help address these issues and improve adherence to recommendations.

ID 575- Quality evaluation of French guidelines in primary care infectious disease: An AGREE II assessment

Rémy BOUSSAGEON

University Claude Bernard Lyon 1, Lyon, France

Context: Antibiotic prescription, its nature and its duration are a very common decision-making situation in primary care practice. Clinical practice guidelines (CPGs) are regularly emitted by various organisations on this topic.

Objectives: Our goal is to run a quality appraisal of the current French guidelines, for the most common primary care infectious pathologies.

Methods: We collected all primary care CPGs that are currently prevailing in France through a systematic review of the french website Antibioclic®. For each of these guidelines, a quality assessment was run by 3 independent reviewers, by means of the Appraisal of Guidelines for REsearch & Evaluation II instrument. The main outcome was a 'reliability score', defined as the sum of the scores in domains 'rigour of development' and 'editorial independence'. To be considered 'reliable', the CPG had to reach a 60% threshold in these two domains. Secondary outcomes were as follows: global quality score of CPGs, number and ratio of CPGs for which a systematic review has been conducted during its conception.

Results: Over the 43 CPGs that have been assessed, none reached the 60%-threshold as to the reliability score. Only one CPG (2.33%) gets an over-60% quality assessment in the domain of rigour of development (D3), whereas three CPGs (6.98%) reach this threshold in the domain of editorial independence (D6). One CPG (2.33%) met the quality threshold of 60% as to overall assessment. Rigour of development and editorial independence are the domains that obtained the lowest average score, respectively, 11% and 21%. Overall assessment received an average score of 29%. A systematic review of the literature was mentioned for 10 CPGs (23.26%).

Discussion: Most clinical practice guidelines in infectious diseases for primary care do not meet minimum quality criteria. This raises questions both about the recommendations issued for antibiotic prescriptions and about the reliability of these guidelines.

Conclusion: There is a lack of quality in the development process of the current French guidelines in primary care infectiology. This process should be reconsidered, with higher insistence as to its quality

Corresponding author: Rémy Boussageon, remy.boussageon2@wanadoo.fr

ID 385- Assessing the quality of evidence cited in French clinical practice guidelines for infectious diseases in primary care

Rémy BOUSSAGEON

University Of Lyon 1, Lyon, France

Context: Guidelines help practitioners make decisions in their daily practice. To be reliable, they must present the level of evidence for the recommendations (GRADE A, B, C, AE from the French National Authority for Health).

Objectives: To assess the level of evidence supporting antibiotic therapy recommendations inprimary care.

Methods: After collecting the clinical practice guidelines (CPGs) listed on the Antibioclic®website (https://antibioclic.com), each recommendation regarding whether or not to prescribeantibiotics was evaluated based on whether it included a GRADE classification by the French National Authority for Health (HAS): A, B, C, or Expert Opinion (EO). The sources cited by the CPGs were reviewed. The recommendations and studies had to answer the question: ‘‘Should antibiotic therapy be prescribed in this situation?’’ The possible answers were ‘‘yes,’’ ‘‘no,’’ or‘‘conditional yes,’’ meaning delayed prescription. The primary outcome was the percentage of recommendations for which supporting studies were cited, in comparison to the stated GRADE.

Results: A total of 152 recommendations from 49 CPGs on antibiotic prescription were analyzed. In all, 71.7% did not mention a level of evidence, 3.3% were classified as GRADE A, and 9.2% as GRADE B. Upon reviewing the studies used to justify the recommendations, high-qualityevidence was identified for only 7.9% of the recommendations, while 80.9% had no referenced studies.

Discussion: More than three-quarters of antibiotic prescription recommendations in primary care do not have an indicated level of evidence (no GRADE). When a GRADE (A, B, C, AE) was mentioned, only 5/41 (12%) were level A. These results concern the most common situations in general practice and do not apply to hospitalised patients. Thus, most recommendations in favour of prescribing antibiotics in primary care are not based on a high level of evidence (only 14.5% had a GRADE of A or B).

Conclusion: Most French recommendations regarding antibiotic prescription in primary caredo not provide the level of evidence supporting them

GPs and their multiple patients

ID 2099- Designing an addiction module for a lifestyle medicine curriculum in family medicine

Vildan MEVSIM [(1)] , Irfan YURDABAKAN [(2)]

(1) Dokuz Eylul University Faculty Of Medicine, Department Of Family Medicine, Izmir, Türkiye
(2) Dokuz Eylul University Faculty Of Education Department Of Measurement And Evaluation In Education, Izmir, Türkiye

Context: Addictive substances, including tobacco, alcohol, and other psychoactive drugs, constitute a major burden on individual and public health. Family physicians play a central role in prevention, early detection, brief intervention, and long-term follow-up of substance use disorders. Lifestyle medicine, with its focus on behaviour change, patient empowerment, and holistic care, provides a suitable framework for addressing addiction in primary care. However, addiction-related competencies are often fragmented or insufficiently integrated into family medicine training curricula.

Objectives: This study aims to design an education module on addictive substances within a lifestyle medicine curriculum for family physicians. The module is based on predefined learning objectives

addressing knowledge, skills, and attitudes related to addictive substances and addiction management in primary care.

Methods: Following a completed needs analysis and learning objective development phase, core competencies for the addiction module were defined. These include defining risky and addictive substances; explaining their biological, psychological, and social effects; recognising stigma and common misconceptions; developing empathetic attitudes; assessing addiction severity; applying evidence-based prevention and counselling strategies; establishing effective communication; developing individualised management plans; and referring patients to appropriate treatment services. Educational strategies and assessment methods are currently being mapped to these objectives using principles of adult learning, experiential learning, and lifestyle medicine education.

Results: The proposed module integrates interactive and practice-oriented educational methods, such as case-based discussions, reflective exercises, skills training, and simulated patient encounters. The curriculum framework aims to strengthen family physicians' competencies in both clinical management and person-centred communication while promoting stigma-sensitive and empathetic care approaches.

Discussion: Aligning addiction education with lifestyle medicine principles enables a comprehensive and behaviour-focused approach that goes beyond disease-centred models. This structured curriculum design supports the development of sustainable competencies relevant to real-life primary care settings.

Conclusion: This study presents a systematic approach to translating addiction-related learning objectives into an educational module within a lifestyle medicine curriculum for family medicine. The proposed framework may guide future curriculum development initiatives and contribute to more effective, compassionate, and integrated addiction care in primary care practice.

ID 1918- Experiences of general practitioners when they receive gifts from their patients

Alice DEROME LE BRET, Sophie PONDAVEN

Université Versailles-Saint-Quentin-En-Yvelines, Paris, France

Context: General practitioners frequently receive gifts from their patients, although accepting gifts in exchange for medical services is prohibited. This practice can have consequences for the unique doctor-patient relationship and its ethical and professional aspects.

Objectives: Explore the experiences and perceptions of XXX general practitioners when they receive gifts from their patients.

Methods: This qualitative study was inspired by interpretive phenomenology and used semi-structured individual interviews conducted either face-to-face or by videoconference. Twelve general practitioners were recruited. Data were analysed using triangulation.

Results: The gift was part of a socio-cultural ritual that fostered exchanges between doctor and patient and could be understood as a symbolic expression of occasional gratitude, sometimes expected by physicians, and reflecting the care relationship. By maintaining a form of reciprocity, it echoed this relationship and appeared more agonistic than purely altruistic in nature. In some cases, it reflected a patient's desire to strengthen or rebalance the relationship, or to seek a secondary benefit. Physicians expressed concerns about possible attempts at corruption, which could lead to expectations or forms of control. Gifts and expressions of gratitude were also perceived as potentially intrusive, encroaching on the consultation or the physician's private sphere. Several physicians emphasized the need to reflect on their own conception of gift-giving throughout their practice, in order to define professional boundaries and establish a framework consistent with their personal values.

Discussion: Drawing on the work of sociologists such as Mauss and Sherry, and combined with the specific features of the care relationship, a new conceptual framework emerges that helps to understand the place of gifts within medical

practice. To limit confirmation bias and the halo effect, a logbook was maintained and data analysis was triangulated. However, the limited heterogeneity of the sample may have resulted in insufficient data. In addition, the researcher's gender may have influenced the exploration of certain themes, particularly those related to the potential sexualization of gifts.

Conclusion: Through the issue of gifts, the general practitioner is led to reflect on the context of the consultation and to question the nature of the doctor–patient relationship, including professional boundaries and expectations.

ID 1273- Prehospital Management of Cardiorespiratory Arrest: Assessment of Knowledge Among Family Physicians

Eya OUERGHI, Wiem DEMNI, Yassmine WALHA, Wafa DAYEM, Wided BAHRIA, Emna AYACHI, Lina HAMDI, Nourelhouda NOUIRA

Emergency Department,mongi Slim University Hospital, Tunis, Tunisie

Context: Cardiorespiratory arrest (CRA) represents the most critical medical emergency. As frontline providers, family physicians are often required to intervene before the arrival of specialized emergency teams, giving them a pivotal role in the early management of out-of-hospital CRA.

Objectives: The aim of this study was to assess the theoretical knowledge of family physicians regarding prehospital CRA management.

Methods: We conducted a two-month cross-sectional descriptive study using an anonymous self-administered questionnaire distributed via Google Forms. The survey consisted of two sections: demographic and training-related information, followed by an assessment component comprising 15 multiple-choice questions inspired by the European Resuscitation Council guidelines.

Results: A total of 110 responses were collected from physicians with a mean age of 34 ± 7 years and a sex ratio of 0.32. Thirty-eight participants (34.6%) were practicing physicians with an average of 9±7 years of experience. Nearly half had received theoretical training during specialty coursework (14.5%), postgraduate training sessions (31.8%), or complementary certification courses (5.5%). Practical simulation-based training had been completed by 79% of participants, with 38.5% trained within the past year. Forty-three physicians (39%) had previously managed an out-of-hospital CRA. The mean score was 11 ± 2 (range: 4–15), and 58 participants (52.7%) achieved a "satisfactory" score (≥11). A satisfactory level was significantly associated with previous theoretical training (p=0.01), practical simulation training (p=0.004), recent training within the past year (p= 0.004), and prior experience in emergency medical services (p=0.04).

Discussion: In a study done by Zajic et al.[1] they concluded that prehospital physicians make decisions to start or withhold resuscitation routinely and base those mostly on situational information and immediately available patient information known to impact outcomes. A clinical paper written by Nagashima et al.[2] evaluated how the presence of prehospital physicians impacts survival outcomes in out of hospital cardiac arrest patients, particularly those undergoing extracorporeal CPR (ECPR). Findings suggest a positive survival effect when a physician is present during prehospital care, indicating the value of physician expertise in acute cardiac arrest management.

Conclusion: Continuous, up-to-date theoretical and practical training in out-of-hospital CRA management is essential to strengthen early intervention quality and ensure adherence to evolving international resuscitation guidelines.

ID 1218- General Practitioners' Attire in XXX: A Descriptive Study

Axel DESCAMPS

Lille University, Lille, France

Context: Several studies have examined the impact of physician attire during consultations, showing its influence on the doctor–patient relationship. However, there is no consensus regarding general

practitioners' (GPs) dress code in office practice, and no descriptive study has comprehensively assessed this in XXX.

Objectives: The primary objective was to describe the attire of general practitioners in XXX. Secondary objectives included assessing the influence of the COVID-19 pandemic on GPs' attire and exploring their reflections on, and reasons for, choosing their professional clothing.

Methods: A descriptive, observational, cross-sectional, quantitative study was conducted in XXX. A random sample of 1,113 GPs was recruited via standardized telephone calls. Data were collected using a questionnaire. Independence of variables was assessed using Chi-square tests or Fisher's exact tests.

Results: Among 1,113 contacted GPs, 362 responses were obtained. In 2022, the most frequently worn attire was semi-formal (25.1%), followed by the white coat (23.4%), white top (20.4%), casual (20.4%), formal (8%), and full white outfit (2.2%). Grouped categories showed that "professional" attire was most common (46.4%), followed by "formal/semi-formal" (33.1%) and "casual" (20.4%). COVID-19 influenced attire toward more professional clothing ($p < 0.001$). The majority of GPs believed that attire affects first impressions (85.4%) and the doctor–patient relationship (77.9%), and reflected on their attire choices (77.6%). Main reasons for attire selection were hygiene, comfort, professionalism, and patient trust. Differences by gender were observed: women prioritized professionalism and comfort, while men emphasized patient trust and perceived empathy ($p < 0.05$).

Discussion: Our findings align with international data indicating that attire impacts patients' first impressions and the doctor–patient relationship. The study population is representative of regional and national GP demographics, supporting external validity. Although the study faced potential selection and measurement biases, these were mitigated through standardized recruitment, photographic examples of attire, and validated questionnaires. Overall, our results suggest that physician attire is a relevant, modifiable factor in clinical practice, shaped by personal, cultural, and situational considerations, with implications for patient perception and the professional image of general practitioners.

Conclusion: Attire choices affect patient perception and the doctor–patient relationship, suggesting that awareness of attire can guide clinical practice and inform medical training for general practitioners.

ID 981- Improving the detection of addictive disorders in primary care: pluriprofessional nominal groups

Agathe EDELINE

Ccu, Tours, France

Context: France is one of the European countries most affected by the consumption of alcohol, tobacco and illicit substances. These uses represent the leading cause of avoidable mortality, with almost 115,000 deaths annually. Despite HAS recommendations in favor of early detection using standardized tools, such screening remains difficult to implement in primary care. Patients fear judgment and stigmatization, while healthcare professionals cite frustration at failure, fear of hindering the doctor-patient relationship, and lack of resources for management. Other primary care professionals, such as physiotherapists, midwives, dental surgeons, nurses or pharmacists, sometimes feel illegitimate to broach these subjects, even though they enjoy a close relationship with patients.

Objectives: Identify what could help primary care professionals to address addictive disorders with their patients.

Methods: A qualitative study was conducted using nominal groups, bringing together general practitioners, nurses, midwives, pharmacists, physiotherapists and dental surgeons. They had to have a primary care practice and were not required to be experts in addictology. Participants were asked to respond to the question "In your practice, what would help you address addictive behaviors with your patients?" Each session followed a standardized procedure: individual formulation of ideas, pooling, clarification and voting. The responses were analyzed to extract the priority ideas according to the participants.

Results: Two nominal groups of 12 and 10 participants respectively, lasting 131 and 122 minutes, were conducted in July and October 2024. The nominal groups yielded 12 and 16 main ideas respectively. At the end of the vote, a 50% cut-off was used to retain 8 ideas expressed by primary care professionals to help them deal with addictive disorders with their patients.

Discussion: These elements aim to reassure, legitimize and equip primary care professionals to engage in dialogue about addictive behaviors. They underline the importance of everyone's role, the need for a non-judgmental framework, and the value of simple tools adapted to daily practice.

Conclusion: The results will be validated using the Delphi method with a multi-professional panel, including primary care professionals, public health experts and patients.

Corresponding author: Agathe Edeline, agathe.edeline@univ-tours.fr

ID 955- What questions should be asked when dealing with addictive disorders in general practice?

Agathe EDELINE [(1)] , Maxime PAUTRAT [(2)]

(1) Ccu, Tours, France
(2) Pr, Tours, France

Context: Early detection of addictive disorders in primary care is recommended but remains underutilized. General practitioners would like examples of questions to ask about addictive disorders during consultations. There is no validated test that can detect all types of addiction.

Objectives: To determine the most appropriate validated questions for broaching the subject of addiction during consultation.

Methods: We selected 15 non-substance-focused questions by cross-referencing data from validated tests, the DSM-V, and nominal groups. A quantitative study was conducted between November 2024 and April 2025 among general practitioners and interns recruited in private practices, health centers, and at national conferences. Participants rated their comfort level with asking each of the 15 questions on a Likert scale.

Results: A total of 201 general practitioners responded. The sample was diverse in terms of status, gender, type, and location of practice. The three highest-ranked questions were: “Have you ever tried unsuccessfully to reduce or stop a consumption or behavior?” (Q4), “Has a consumption or behavior ever caused you problems?” (Q6), and “Do you need a substance or behavior to relax, feel better, or cope?” " (Q7). The question about the patient's social circle (Q13) was the lowest rated.

Discussion: Three questions emerged as particularly useful for GPs in dealing with addictions, asking about the difficulty of quitting, the problems involved and using to feel better. Their convergence with recognized tools confirms their clinical relevance, while the low value of questions focusing on the entourage illustrates the fear of being intrusive.

Conclusion: This study highlights three simple, validated, and cross-sectional formulations that general practitioners perceive as appropriate for broaching the subject of addiction. Testing them in real-life conditions and adapting them to other primary care professions is a relevant avenue for further research.

ID 496- Exercise Addiction in Primary Care: Prevalence, Associated Factors, and Patient–GP Dialogue in a Community-Based Sample

Louise FUMERY, Jan BARAN

Université De Lille, Lille, France

Context: Exercise addiction (EA) is characterised by compulsive physical activity despite physical or psychological harm. Although its prevalence is well described in athletic and fitness populations, little is known about its presence in routine primary care.

Understanding EA within general practice is essential, as early identification may prevent physical, social and psychological complications. The patient–GP dialogue around exercise could play a role in detecting at-risk individuals.

Objectives: Estimate the prevalence of exercise addiction among adult primary care patients, and to identify associated behavioural, clinical, and communication-related factors, including discussions about exercise with GP.

Methods: A cross-sectional multicentre study was conducted from June 2024 to January 2025 across general practices belonging to a Territorial Professional Health Community (CPTS) in northern France. Adult patients completed an anonymous self-administered questionnaire assessing sociodemographics, physical activity habits, substance use, and sport practices. Exercise addiction risk was measured using the Exercise Addiction Inventory. Participants reported whether they discussed exercise with their GP. Analyses (logistic regression models) were performed on the full sample and on the subgroup of participants reporting regular physical activity.

Results: Among 402 respondents (64.4% women), 6.2% (95% CI 3.8–8.6) were at risk of EA. Independent associations included self-medication (OR 12.1), use of rehydration drinks (OR 37.5), and discussing physical activity with the GP (OR 3.1). In the physically active subgroup (n = 290), 8.6% (95% CI 5.4–11.8) were at risk. Associated factors included self-medication (OR 35.7), rehydration drink use (OR 36.0), endurance sports (OR 4.7), combat sports (OR 35.5), and exercising ≥4 times per week (OR 10.2).

Discussion: This study provides a primary care–based estimate of EA, suggesting that EA may be more common than expected. The strong associations with specific sports and health-related behaviours highlight red flags that GPs can monitor. At-risk individuals appear more likely to discuss physical activity with their GP, suggesting an opportunity for early detection.

Conclusion: Exercise addiction may affect up to one in twelve physically active primary care patients. Increased GP awareness, targeted screening, and structured dialogue about exercise behaviours could support earlier recognition and tailored counselling. Further research is needed to refine screening strategies and assess management approaches within primary care.

GPs working conditions

ID 2242- Evaluation of the online reputation of general practitioners by their patients in the Landes department in 2024

Jean-Philippe JOSEPH, Maxime BANNIER, Marco ROMERO

Département De Médecine Générale-Université De Bordeaux, Bordeaux, France

Context: The online reputation of general practitioners is an expanding phenomenon and raises ethical, legal, and practical issues in the context of the growing digitization of healthcare services. Google®, through its business listings, has become the main platform for such evaluations.

Objectives: The aim of our study was to examine the nature and determinants of online reviews concerning general practitioners in the Landes department in France, published on Google in 2024.

Methods: A mixed-methods observational study combined a cross-sectional quantitative analysis of the Google® list of general practitioners (GPs) and healthcare facilities identified via the Health Insurance in October 2024, and a qualitative analysis of published reviews. Data collected included ratings, reviewer status presence of written comments, and GP characteristics (gender, practice type, location, additional activities). A thematic categorization of comments was conducted into three main domains: doctor–patient relationship, medical competence, and office organization.

Results: Among the 473 GP and healthcare structures studied, 63% had a Google® listing, and 58% had received at least one review. The average rating was 4.2/5, with 92.3% of extreme evaluations. Qualitative analysis of 3,036 published reviews revealed a predominance of relational criteria: listening (669 mentions), kindness (638),

and competence (645). In contrast, organizational aspects (reception, appointment scheduling, punctuality) were less often mentioned and more frequently associated with negative comments. GP practicing in rural areas, those with a specific medical focus, or those working alone generally received more positive evaluations. Conversely, healthcare structures, though receiving more reviews, were rated less favorably overall. Practice setting emerged as a major discriminating factor in the nature of comments. Lastly, reviewers identified as “Local Guides” (27.5% of evaluators) gave more moderate ratings.

Discussion: The online reputation of GP is generally positive but highly polarized. It is primarily shaped by relational aspects of care, rather than technical or organizational criteria. Google® has established itself as the central platform for digital reputation, accounting for 93% of reviews. Our comprehensive data did not include the age of GP and may change with the territory.

Conclusion: These findings offer valuable insights into patient expectations and could serve as a lever for improving practices in general medicine.

Corresponding author: Maxime Bannier, maxime.bannier@u-bordeaux.fr

ID 1866- Reducing abusive requests for medical certificates: collaboration between certificats-absurdes.fr and eleven Departmental Medical Councils in France

Michaël ROCHOY [(1)] , Idriss MODSON TAVAZE [(2)], Camille HONG [(3)]

(1) Univ. Lille, Outreau, France
(2) Univ. Lille, Lille, France
(3) Univ. Paris, Paris, France

Context: The number of practising general practitioners in France is decreasing, while the population is growing and ageing. Preserving medical time has become a priority, particularly by reducing administrative workload. General practitioners estimate spending on average 1.5 to 2 hours per week dealing with unjustified medical certificates. To address this issue, a collaborative initiative was launched between the website XXX and eleven Departmental Medical Councils (Conseils Départementaux de l’Ordre des Médecins, CDOM) to provide evidence-based responses on whether medical certificate requests were justified or not.

Objectives: To describe the types of medical certificate requests considered abusive by general practitioners and reported to CDOMs through this initiative.

Methods: We conducted a prospective, multicentre, descriptive study from July 2023 to December 2025 (2,5 years) involving the following CDOMs: XXXXXXXXXXXXX. General practitioners affiliated with these CDOMs could submit requests they considered abusive by email. A personalised response was written by author, then provided to both the physician and the requester, including references to applicable legislation when relevant. All complaints received were included. Each request was classified by domain (insurance contracts, school-related, sport, work, healthcare, etc.), and its legal status was assessed through a review of LegiFrance and CDOM regulatory guidance.

Results: A total of 423 complaints were received: 285 from the XXXX department (67%). Requests mainly concerned insurance or disability contracts (N=180; 43%), school or extracurricular settings (N=78; 18%), work and healthcare-related issues (N=47; 11%), and other requests such as training or sport (N=118; 28%). Overall, 78% of requests were judged abusive, or illegal (including breaches of medical confidentiality).

Discussion: The main strength of this study is its longitudinal and multicentre design, confirming the high frequency of medical certificate requests without legal basis, particularly from insurance providers and the school sector. Limitations include restricted geographical coverage (11 of 99 CDOMs) and variable physician engagement between departments. A qualitative study could help further improve the initiative.

Conclusion: This work supports targeted communication with institutions to prioritise action on the most problematic certificate requests: insurance, schools, and sports. Scaling up this initiative at the national level, in collaboration with the National Medical Council or French Nationa Health Insurance would be helpful.

Corresponding author: Michaël Rochoy, michael.rochoy@gmail.com

ID 1646- Perceptions of private general practitioners in northern France faced with requests for remote consultations from their families.

Camille OBERT-MARBY, Florian TIRODE

Faculté De Médecine Maieutique Et Sciences De La Santé, Lille, France

Context: A doctor's family may ask them for a diagnosis, a prescription, a certificate... In this age of telemedicine and tele-expertise, in a hyperconnected society, it has become easy to ask a relative who is a doctor for medical advice via their personal messaging service. However, few studies have looked at how these family doctors feel about this.

Objectives: To understand and explore the views of private general practitioners in (XXX) on remote consultations conducted via unsecured tools (personal email, text messages, social media) at the request of their family members, and the consequences on their personal and professional lives.

Methods: Qualitative study using semi-structured individual interviews, audio-recorded with general practitioners practising privately in (XXX). Full verbatim transcription followed by analysis of the transcripts and non-verbal communication data on an ongoing basis according to phenomenology, with triangulation of coding. Interviews stopped once sufficient data had been collected.

Results: Thirteen general practitioners participated. They consider the requests easy and quick to deal with, but exhausting because they are recurring. The satisfaction and pride of having helped their loved ones was overshadowed by the anxiety caused by more complex requests. The lack of objectivity and the absence of elements found in a face-to-face consultation, such as an in-depth interview or clinical examination, could result in a loss of opportunity for the requesting parent.

Discussion: Receiving requests from loved ones is inevitable, especially in areas with a shortage of medical professionals. One must learn to be a doctor for one's family from university onwards, and sometimes know how to impose a formal framework and rules to protect oneself... or choose to refuse, know how to say no and refer the patient to a colleague for objective care.

Conclusion: Any doctor may be called upon by a member of their family and must be prepared for this. But educating families also seems essential: their doctor, with their strengths and weaknesses, must be able to enjoy moments of relaxation with or without them, and they must be allowed 'to simply not work outside of working hours'.

Corresponding author: Camille Obert-Marby, obert.camille@orange.fr

ID 1513- TAMGE: Study of working time, activity, and modes of private and salaried practice in outpatient general medicine in Nouvelle-Aquitaine and Île-de-France.

Jean Luc GALLAIS [(1)] , Frederic CHEVALLIER [(1)], Alexandre CARON [(2)], Laura BEZANNIER [(2)], François RAINERI [(1)]

(1) Sfmg, Issy-Les-Moulineaux, France
(2) Cemka, Bourg-La-Reine, France

Context: French general practice is undergoing profound transformations, marked by increasing waiting time for a general practitioner, feminization of the profession, and a shift toward salaried practice, creating a dual system amidst access-to-care tensions

Objectives: To describe and compare the real-world activity (care, coordination, and administration)—and working conditions of General Practitioners (GPs) based on their practice model (private/mixed versus exclusive salaried) in two contrasting regions: Nouvelle-Aquitaine and Île-de-France.

Methods: Across-sectional observational study was conducted in 2025. From 1,787 eligible respondents, 499 GPs provided detailed prospective data regarding a randomized typical workday.

Results: The study reveals two distinct, complementary ecosystems. Among exclusive private GPs (N=356), most worked in group offices (56.4%), private health centers (“Maison de santé” 27.0%), or solo practice (22.5%). Exclusive salaried GPs (N=92) were predominantly based in public health centers (“Centre de santé”, 70.7%), with additional activity in hospital facilities (37.0%). The private/mixed model (81.6% of the sample)is characterized by high intensity: 22.1 procedures/day, 9.3-hour workday. It remains the pillar of longitudinal follow-up (78.6% of patients seen are their own), out-of-hours duties (40.0% participation), and training (48.4% are internship supervisors(‘’MSU’’).However, 60.4% report excessive administrative burden By contrast the salaried model (18.4% of the sample) offers a protected framework: shorter days (8.4 hours)and fewer procedures(16.4/day).It acts as a social "safety net," managing significantly more patients with economic difficulties(45.7% vs. 17.0%) and those without designated primary GP (13.1% vs. 3.7%). However, continuity of care is lower (35.6% own patients), and appointment non-attendance is higher (9.9% vs. 3.0%).Various others results come from analyses according to regions, GPs ’age and MSUs ’activity

Discussion: TAMGE highlight new needs to optimize patients’ pathways according to populations, health services and traditional or new health providers involved.

Conclusion: TAMGE report the functional duality of French primary care: a private sector ensuring volume and continuity but facing administrative saturation, and a salaried sector focused on access for vulnerable populations. Future policies must apply differentiated support to alleviate administrative weight on private GPs and secure medical training capacity, which currently relies heavily on the private sector.

Corresponding author: Jean Luc Gallais, jl.gallais@sfmg.org

ID 1081- Factors influencing the establishment of general practitioners in France and its overseas territories from 1998 to 2024

Fannie DUCHAYNE [(1)], Thomas MOREL [(2)] , Jeanne DARFEUILLE [(1)], Lise PLEYBER [(2)]

(1) Nantes, Nantes, France
(2) Dmg Nantes, Nantes, France

Context: The difficulty of accessing primary care is a key issue at the national level, as evidenced by the recent debate on restrictions on the freedom to settle. The lack of general practitioners in France exacerbates inequalities in access to healthcare, a phenomenon aggravated by the dysfunctional nature of the French healthcare system. The establishment of new doctors therefore appears to be essential to guarantee access to healthcare for all. In this regard, healthcare authorities can play a key role in encouraging general practitioners to set up practices by using levers that have yet to be identified.

Objectives: Main objective: Identify the motivations, sustainability, and obstacles to the establishment of young French general practitioners exercising in private practice. Secondary

Objectives: identify political drivers for establishment, identify trends according to profiles (interns, established practitioners, substitute practitioners), identify whether the study methodology has an impact on the results.

Methods: A systematic review of the literature was conducted to answer the question. Bibliographic databases (Medline, Web of Science, Cairn) were searched using an original search equation. Studies were selected in duplicate and each article was analyzed individually. Determinants were extracted from the included studies and classified into categories and then subcategories. A subgroup analysis was performed according to the profile of the physicians interviewed and the methodology of the studies.

Results: The systematic review included 81 original articles and theses. The analysis identified eight categories of determinants. The most frequently cited determinants are those related to the organization of care, both professional and private. The subgroup analysis identified the main determinants for setting up practice: the partner's place of work, setting up in a group practice, and simplification of administrative procedures.

Discussion: This study is systematic and original. Its main limitations are the analysis of individual articles, the biases inherent in each methodology (quantitative and qualitative), and the lack of data on the sustainability of physicians' practices after setting up.

Conclusion: This review could offer useful insights to decision-makers on how to promote the long-term retention of general practitioners.

Corresponding author: Fannie Duchayne, fannie.duchayne@gmail.com

ID 975- Factors associated with the well-being of family physicians practicing in Quebec: Results from a Canadian survey

Jophildy KIAMBATI [(1)] , Emmanuelle BRITTON [(2)], Géraldine LAYANI [(1)], Erin STRUMPF [(3)], Maude LABERGE [(4)], Catherine HUDON [(5)], Réal BARRETTE [(2)], Nadia SOURIAL [(1)]

(1) Centre De Recherche Du Centre Hospitalier De L'université De Montréal (crchum), Montreal, Canada
(2) Ministère De La Santé Et Des Services Sociaux, Montreal, Canada
(3) Université Mcgill, Montreal, Canada
(4) Université Laval, Québec, Canada
(5) Université Sherbrooke, Sherbrooke, Canada

Context: According to the Canadian Medical Association, over 50% of family physicians are experiencing professional burnout. The lack of well-being among family physicians has significant impacts at both the individual and healthcare system levels. Few studies have examined the well-being of family physicians from a multidimensional perspective, while evaluating the relative importance of associated factors.

Objectives: The purpose of this study was to examine the relative importance of individual factors and external factors associated with their level of well-being.

Methods: Cross-sectional study design based on a survey of family physicians conducted between December 2023 and July 2024, to all practicing family physicians in Quebec. An ordinal logistic regression was performed.The main measure was the 9-item Physician Well-Being Index (PWBI). According to the index, a score of 3 or higher indicates a risk of low well-being. The independent variables (demographic and organizational charcteristics), chosen according to Brigham et al.'s (2018) framework.

Results: Participants in this study were family physicians practising in Quebec, Canada (N=1252). Nearly two thirds (62.5%) of participants were at risk of low well-being. In order of importance, the major factors associated with well-being were satisfaction with work-life balance, feeling fulfilled in one's role as a family physicians, often facing excessive expectations or verbal abuse from their patients, satisfaction with human resources, and finally, awareness of governmental actions aimed at improving family physicians' well-being and job satisfaction.

Discussion: Nearly two thirds of family physicians in Quebec showed poor well-being, similar to the 57% found in Belgium Cholewa et al (2024). Satisfaction with work-life balance was the most influential factor for their well-being. Other important aspects included feeling fulfilled in one's role as a family physicians, frequently facing excessive expectations or verbal abuse from patients, satisfaction with human resources, and awareness of governmental actions aimed at improving family physicians' well-being and job satisfaction. This study contributes to the scientific literature, notably by prioritizing factors influencing family physicians' well-being and proposing a framework for prioritizing interventions.

Conclusion: The results of this study show a low level of well-being among family physicians and highlight priorities for policy and interventions aimed at improving the well-being of family physicians.

ID 657- The experience of recently retired general practitioners

Guillaume GENIN

Paris Sorbonne University, Paris, France

Context: Retirement is a lived process that can be complex, questioning the identity of the newly retired individual. A genuine topic of political relevance, retirement also concerns physicians, whose demographics have been closely monitored for several decades in the face of growing medical desertification. Moreover, the profession of general practitioner appears to carry strong intrinsic value, imbued with meaning and significant social recognition.

Objectives: To explore the lived experience of the transition in social status from active general practitioner to retired physician.

Methods: A qualitative phenomenological study conducted with general practitioners retired for less than five years. Data were collected through participants' narratives (semi-structured interviews) and a verbal association method. The study was carried out by a single investigator with interview guide and data triangulation.

Results: The study was based on twelve interviews and twenty verbal association between 2022 and 2023. The analysis identified the main components of the retired general practitioner's lived experience. First, in relation to the Other, the patient, particularly regarding recognition and the absence thereof. Second, in relation to the self, especially around the themes of meaning and the identity of the retired physician. Finally, as a major component, the changed relationship to time.

Discussion: The strengths of the study lie mainly in the originality of its subject, the lack of substantial literature on this topic, and its dual methodology. However, its limitations stem from its qualitative nature: recruitment, saturation and data collection, and finally the potential social desirability bias. The discussion revisits the central dichotomy of the topic through the works of various philosophers, sociologists, and physicians: The experience in relation to the Other (Does the patient make us doctors? Desire and absence of the patient, feeling of abandonment, the infinite time of the patient). The experience in relation to oneself (Loss, reconstruction of meaning, identity: sameness/selfhood, time and duration, finitude).

Conclusion: The experience of retired general practitioners appears as a major paradigm shift that is often unanticipated, triggering numerous and sometimes profound cross-cutting questions. The analysis of this lived experience reflects their capacity to adapt to this new stage of life confronting them with the limits of body and time.

How to make a baby?

ID 1888- Promoting pre-conception health in primary care: the importance of ever earlier prevention

Maud JOURDAIN, Bertrand ISIDOR, Stéphanie TELLIER CARRARA

Nantes Université, Nantes, France

Context: According to the DoHad concept, many chronic diseases in adulthood (diabetes, cancer, cardiovascular disease, reproductive health, mental and behavioural disorders, etc.) may have their origins in the prenatal period, linked to exposure to environmental factors. The intrauterine period, particularly early during embryogenesis, is a period of high sensitivity to these factors. Environmental factors also affect gametogenesis, particularly sperm quality, which can lead to developmental abnormalities that may be passed on to future children. Promoting preconception health therefore represents a major opportunity for population health. However, professionals lack the resources to address environmental and preconception health.

Objectives: The aim of this project is to develop a communication tool to promote overall health and environmental health among adults who are likely to have children.

Methods: A multidisciplinary team (geneticist, midwife and general practitioner) led this project, which was part of an interventional research programme. The stages consisted of: reviewing the literature, developing an initial framework for the support material, setting up a committee of experts from other disciplines (occupational physicians,

paediatricians, gynaecologists, public health specialists) as well as associations and patients, who were involved in developing the support material through iterative reviews and proposals during various consultation rounds. The FALC (easy to read and understand) guide was used to develop the material.

Results: This inter-professional collaboration with patients resulted in the production of a leaflet based on the concept of the exposome, addressing the various relevant exposure factors: diet, air quality, cosmetics, toxins, medical factors, occupational exposure and stress. It takes a positive approach, focusing on resources.

Discussion: It is intended for distribution to healthcare professionals who are in contact with the relevant population in order to encourage open dialogue about overall health in the pre-conception period, during dedicated consultations or otherwise. It is suitable for those planning to become parents, but the overall health aspect also applies to people who are not planning to become parents or are undecided. Accessibility is not sufficient for people with difficulties accessing written language in particular.

Conclusion: Additional work is planned to adapt teaching materials and methods in particular to the level of health literacy.

ID 2041- Characteristics of fathers of children with fetal alcohol spectrum disorder in Reunion Island

Vanille AUPERIN, Thierry MAILLARD, Michel SPODENKIEWICZ, Sébastien LERUSTE

Chu De La Réunion, Saint Pierre, Réunion

Context: Fetal alcohol spectrum disorder (FASD) represents the leading cause of non-genetic neurodevelopmental disability worldwide and remains a major challenge for primary healthcare systems. While maternal alcohol exposure has been extensively studied, paternal factors have received far less attention. Fathers may influence alcohol-related behaviors during pregnancy, family functioning, and long-term child outcomes. A better understanding of paternal characteristics, perceptions, and involvement is therefore essential to inform more inclusive prevention and support strategies in family medicine.

Objectives: This study aimed to characterize the sociodemographic profiles, alcohol and substance use patterns, levels of involvement, and perceptions of fathers of children diagnosed with FASD.

Methods: A cross-sectional descriptive study was conducted among fathers of children diagnosed with FASD on Reunion Island. Eligible participants were biological fathers who agreed to take part in the study. Data were collected using semi-structured, interviewer-administered questionnaires covering sociodemographic characteristics, health status, substance use, paternal involvement, and perceptions of fatherhood and FASD. Quantitative data were analyzed using descriptive statistics, and qualitative data were examined through thematic analysis to identify recurring patterns and perceptions.

Results: Ten fathers were included. Most participants experienced social vulnerability, characterized by low educational attainment, unstable employment, and limited access to health information. Alcohol consumption prior to pregnancy was frequent, with several fathers reporting regular use. Following the child's birth, many fathers described a reduction in alcohol consumption, often linked to increased parental responsibility. Paternal involvement during pregnancy and child-rearing varied according to relationship status and family context; however, a strong willingness to support both the child and the mother was consistently expressed. Although general awareness of the risks associated with alcohol use during pregnancy was high, knowledge of FASD as a clinical entity, including its diagnosis and long-term consequences, remained limited.

Discussion: These findings suggested a discrepancy between general prevention messages and fathers' understanding of FASD, highlighting an unmet need for targeted paternal education in primary care settings.

Conclusion: Fathers of children with FASD demonstrate both social vulnerability and adaptive behavioral changes following parenthood. Integrating fathers more systematically into

prevention, counseling, and support interventions may strengthen family-centered approaches to fetal alcohol exposure and improve equity in primary healthcare.

ID 1518- Dedicated consultation for first-time fathers during pregnancy in general practice: patient satisfaction and needs

Clémentine WARGNIER, Flore MALRIEU, Jean-Christophe POUTRAIN, Elodie BELOT

Dumg De Toulouse, Montréjeau, France

Context: In France, a prenatal consultation for the co-parent is provided for in the Public Health Code, yet it remains poorly known. No study has evaluated the feasibility or acceptability of a consultation dedicated to first-time expectant fathers in general practice

Objectives: To determine whether this consultation meets first-time expectant fathers needs and to identify areas for improvement to optimize its implementation and dissemination

Methods: A multicentric quantitative descriptive cross-sectional observational study was conducted among French-speaking adult expectant fathers. After a consultation enriched by our DES work and delivered by a volunteer general practitioner, participants completed a questionnaire assessing the content, their satisfaction, and their suggestions for improvement.

Results: Sixteen men participated. None were aware of the existence of such a consultation. It was considered relevant, ideally offered early in pregnancy and conducted by a general practitioner. The most relevant topics concerned the partner and the unborn child. Physical health topics generated less interest, while mental health, although positively perceived, remained secondary.

Discussion: Recruitment difficulties highlight the low visibility of this service and the challenge of mobilizing expectant fathers. The results confirm the feasibility and value of a dedicated space for expectant fathers, and stress the need to raise awareness among men and healthcare professionals

Conclusion: This study supports the relevance of a prenatal consultation for first-time expectant fathers in general practice, highlights the general practitioner's key role in including them in perinatal care pathway and paves the way for further studies evaluating its impact.

Corresponding author: Clémentine Wargnier, jeanchristophepoutrain@gmail.com

ID 1517- Experimentation of a Dedicated Consultation for First-Time Fathers During Pregnancy in General Practice: General Practitioners' Perspectives

Malrieu FLORE, Clémentine WARGNIER, Jean-Christophe POUTRAIN, Elodie BELOT

Dumg De Toulouse, Montréjeau, France

Context: In France, the Public Health Code provides for a consultation dedicated to the co-parent during pregnancy. In practice, its feasibility remains unknown, and no study has assessed the opinions of general practitioners after implementing it.

Objectives: To evaluate the opinions and experiences of general practitioners who participated in a pilot consultation dedicated to first-time fathers during pregnancy, as well as their perception of a consultation guide.

Methods: This was a quantitative, cross-sectional, multicenter observational and descriptive study involving general practitioners. The questionnary assessed their opinions and experiences regarding the consultation and the guide, as well as their suggestions for improvement.

Results: Fourteen general practitioners conducted 16 consultations with future first-time fathers. All the topics addressed received favorable feedback, particularly those related to mental health, childbirth, physical health, and sexuality. General practitioners reported feeling comfortable and legitimate in conducting the consultation but emphasized its time-consuming nature and the absence of financial compensation

Discussion: These results confirm general practitioners' interest in providing a consultation dedicated to fathers and its practical feasibility. The consultation guide appears to be a valuable tool to further develop to support practitioners. This pilot experiment, unprecedented in France, warrants further investigation on a larger scale.

Conclusion: This work highlights the central role of the general practitioner in the comprehensive support of parenthood. The consultation with the expectant father represents a key opportunity for screening, prevention, parental support, and fostering greater paternal involvement with the future child.

ID 941- Overview of General Practitioners' and Patients' Knowledge About Gamete Donation

Gal BENEDICTE, Laureline MORENO, Pauline GUEGAN

Dumg Montpellier Nimes, Montpellier, France

Context: The demand for gamete donation is increasing, notably due to new laws regulating it. The number of donors remains stable and insufficient, leading to prolonged waiting times. The main barrier to donation appears to be a lack of information among patients, but also among physicians, who should be key providers of this information.

Objectives: The main objective is to study, on one hand, the knowledge of patients eligible for gamete donation (women aged 18 to 37 and men aged 18 to 44) on the topic, and on the other hand, the knowledge of practicing general practitioners regarding the subject

Methods: This is a descriptive quantitative study based on two knowledge questionnaires addressed to physicians and patients of gamete-donation age. The distribution was carried out through the departmental Medical Councils as well as via social media

Results: A total of 68 patient responses and 95 physician responses were analyzed. Patients and physicians achieved overall mean scores that were not significantly different, 6.95/15 and 7.63/15, respectively. Physicians performed better regarding the practical aspects of donation and the regulations compared to patients. Physicians who had previously discussed the topic with their patients had a statistically higher mean score than those who had not. Ninety-six percent of patients indicated they would not be uncomfortable if their physician raised the issue of gamete donation during a consultation. Nearly 43% of patients said they might consider donating in the future. Ninety-three percent of physicians considered an informational document useful, preferably in the form of a brochure.

Discussion: Since the 2011 decree, the general practitioner has been at the center of providing information on gamete donation. The sample size is insufficient to generalize the results nationally. It appears necessary to strengthen initial medical training, offer continuing education to those who wish, and consider creating a mixed informational resource aimed at both physicians and patients to meet their needs.

Conclusion: Gamete donation is a topic at the heart of current concerns, requiring the enhancement of healthcare professionals' knowledge in order to meet the growing demand from patients.

ID 925- Prevalence of smoking during pregnancy and associated social inequalities in developed countries over the 1995–2020 period: A systematic review

Kim BONELLO, Hugo FIGONI

Sorbonne Université, Paris, France

Context: Smoking during pregnancy (SDP) is an important source of preventable morbidity and mortality for both mother and child.

Objectives: The aim of this study was to describe changes in the prevalence of SDP between 1995 and 2020, in developed countries (Human Development Index >0.8 in 2020) and associated social inequalities.

Methods: A systematic review was conducted based on a search in PubMed, Embase and PsycInfo databases and government sources. Study selection and data extraction: Published studies between January 1995 and March 2020, for which the primary outcome was to assess the national prevalence of SDP and the secondary outcome was to describe related socio-economic data were included in the analysis. The selected articles had to be written in English, Spanish, French or Italian. The articles were selected after successive reading of the titles, abstracts and full-length text. An independent double reading with intervention of a third reader in case of disagreement allowed including 35 articles from 14 countries in the analysis.

Results: The prevalence of SDP differed across the countries studied despite com-parable levels of development. After 2015, the prevalence of SDP ranged between 4.2% in Sweden and 16.6% in France. It was associated with socio-economic factors. The prevalence of SDP slowly decreased over time, but this overall trend masked in-equalities within populations. In Canada, France and the United States, the prevalence decreased more rapidly in women of higher socio-economic status, and inequalities in maternal smoking were more marked in these countries. In the other countries, inequalities tended to decrease but remained significant.

Discussion: The study was conducted using rigorous methodology (PROSPERO registration, diverse databases, validation of the search equation by a methodologist) and reported according to PRISMA Equity 2021 guidelines. However, the articles included in the analysis were compared while they sometimes used different methodologies and timeframes. Furthermore, smoking status was most often self-reported, which may lead to an underestimation of prevalence rates.

Conclusion: During pregnancy, that is a period described as a window of opportunity, smoking and social vulnerability factors need to be detected to implement targeted prevention strategies aiming at reducing related social inequalities

ID 480- Barriers and facilitators to antenatal care by general practitioners

Lynn LIM SHUNG

Université De Liège, Liège, Belgique

Context: Most pregnant women are followed by a gynecologist while only a minority of them are followed by their general practitioners (GP). However, those are allowed to manage antenatal care in case of low risk pregnancy.

Objectives: The aim of this study is to explore the different barriers and facilitators to antenatal care by GP.

Methods: A narrative literature review was conducted using a methodology borrowed from the Scoping review. Five databases were explored : Pubmed, Cochrane, ScienceDirect, PsycINFO and Cismef. Inclusion and exclusion criteria were established. Studies dated from 2015 to 2025, written in English or French, addressing antenatal care and involving management by GP, were included. Studies were excluded if they focused exclusively on management by the gynecologist or midwife, or if they focused exclusively on childbirth, high risk pregnancies, or abortions.

Results: Twenty-four studies were included in our review. Key barriers included the link between the discontinuation of childbirth practice by GP and the decrease in pregnancy follow-ups, the lack of training, the lack of interprofessional coordination and collaboration, insufficient time, inadequate remuneration, and weak continuity of care. Main facilitators included the exposure to training, positive interprofessional collaboration experiences and practice in rural areas or shared-care programs.

Discussion: Five main categories of barriers and facilitators were identified : organizational, institutional, interpersonal, individual, and professional. The main barriers appeared at the organizational and institutional levels. The professional environment influences clinical practice, with GP providing more antenatal care in rural than in urban areas. Differences between

healthcare systems across countries can also be observed, influencing the involvement of GP in pregnancy care. Moreover, eight studies emphasized the important role of GP in addressing perinatal mental health and vulnerability, highlighting the benefits and centrality of their role in antenatal care.

Conclusion: To encourage and support physicians in providing more antenatal care, it would be essential to strengthen care coordination with other professionals, enhance medical training, and encourage policymakers to improve funding for pregnancy follow-up consultations. Further research on patients' perceptions of antenatal care by GP would be valuable to complement our study.

Humanism in care

ID 2014- Violences médicales involontaires en soins primaires ; une revue de littérature

Aurelie JANCZEWSKI, Gabrielle FAGNET, Luc NOCQUET

Dumg Marseille, Marseille, France

Context: Les violences médicales principalement explorées sont les institutionnelles et les gynécologiques. Elles sont pourtant présentes en soins primaires.

Objectives: Cette revue de la littérature avait pour objectif de faire l'état des lieux des violences involontaires de soignants envers les patients en soins primaires et d'identifier les pistes de solutions.

Methods: La recherche documentaire a été réalisée selon les recommandations PRISMA , de mai à juin 2025. Les bases de données consultées étaient : PubMed, Cairn.info, Lissa et Cochrane Library. Les équations de recherche ont été élaborées à partir de termes MeSH combinés par des opérateurs booléens (« AND », « OR », « NOT »). Les principaux termes utilisés étaient "Primary health care", "family physician", "Violence", "discrimination", "stigmatization", "patient mistreatment", combinés avec des termes d'exclusion tels que "hospital", "emergency care", "surgery". Un enregristement sur PROSPERO a été fait.

Results: Ce travail a mis en évidence de multiples formes de maltraitance, surtout sous forme de discriminations, stigmatisations et d'iniquités des soins. Elle touche en premier lieu les populations marginalisées et vulnérables, (telles que les minorités raciales et ethniques, les personnes LGBTQ+, les femmes, les personnes âgées, les patients en situation de précarité socio-économique, en situation de handicap, ou souffrant de troubles psychiatriques, d'addictions ou d'obésité). Ces expériences peuvent impacter les patients sous plusieurs formes: atteinte de la dignité et de l'autonomie, détérioration de la relation thérapeutique, impacts psychologiques et physiques.

Discussion: La force de ce travail est sa rigueur méthodolique et son originalité. Ses limites portent sur le peu d'articles traitant spécifiquement des soins primaires. Ces éléments correspondent aux données de la littérature, dans le domaine de l'obstétrique ou des soins institutionnelles. La normalisation des maltraitances retrouvée dans les différents types de soins impose un questionnement éthique sur sa genèse et sa persistance. Elles peuvent être expliquées par le résultat de mécanismes de défense de la part des soignants en proies à leurs propres difficultés mais aussi plus largement par des violences systémiques reflétant un problème sociétal.

Conclusion: Optimiser la relation soignant-soigné par le biais d'une formation de communication, interculturelle et continue semble être, malgré des preuves d'efficacité demeurant limitées, la solution la plus prometteuse.

Corresponding author: Aurelie Janczewski, aurelie.janczewski@gmail.com

ID 1937- From Rape Culture to an Ethics of Care: What Tools Are Available to General Practitioners (GPs) to Heal and (Re)think Trauma in the Context of Gender-Based and Sexual Violence?

Le Bris ANNE [(1)], Nora GOFFRE [(2)]

(1) Eso Rennes, Rennes, France
(2) Liris Rennes, Rennes, France

Context: Research on trauma related to gender-based and sexual violence (GBSV) shows long-lasting effects on physical, psychological, and social health, exacerbated by silence, shame, and institutional denial. In societies shaped by a rape culture in which rape myths and victim-blaming persist, healthcare systems may—sometimes unintentionally—reproduce relations of domination. General practitioners (GPs) occupy a strategic position to identify, listen to, and support victims, yet they often remain insufficiently trained in comprehensive approaches to gendered social relations.

Objectives: This paper provides an overview of current knowledge articulated with materialist approaches to gendered social relations and aims to highlight concrete implications for general practitioners in order to improve listening practices and strengthen the quality of care.

Methods: The article is based on a narrative and critical review of the literature in public health and the sociology of violence against women, including recent work on rape culture, combined with a multi-sited fieldwork approach. The findings are analyzed from a materialist perspective attentive to social determinants of health, power relations, and institutional forms of violence and silencing within care settings.

Results: Rape culture—and more broadly popular culture through the banalization and normalization of violence—shapes professional representations and practices, including those of general practitioners.

Discussion: A materialist approach to gendered social relations makes it possible to understand GBSV as structural violence intertwined with economic inequalities and gender hierarchies. For general practitioners, this entails shifting perspectives by questioning the power relations that run through patients' life trajectories and the clinical relationship itself.

Conclusion: Training general practitioners (GPs) on these issues is essential to ensure safe and reparative care. Integrating tools for identifying GBSV, practicing active listening, and developing critical reflection on rape culture and gendered social relations into both initial and continuing medical education is a central condition for establishing a genuine ethics of care.

Corresponding author: Nora Goffre, nora.goffre@univ-rennes2.fr

ID 1574- Description of the feelings experienced by general practitioners when accompanying patients in distress in palliative care situations

Andréa TAROT [(1)] , Lucie DELVAL [(2)], Delphine MARTINEAU [(1)], Axelle MANEVAL [(1)], Hélène VAILLANT-ROUSSEL [(1)]

(1) Acceppt, University Clermont-Auvergne, France
(2) Uca, University Clermont-Auvergne, France

Context: The concept of distress has been developed to describe the specific experiences of patients in palliative care. This concept makes it possible to de-psychiatrising these situations.

Objectives: The aim of this study was to explore general practitioners' feelings about the distress of palliative care patients and to better understand the patient-doctor relationship in these situations.

Methods: The epistemological approach of the study was based on a constructivist paradigm. Interpretative phenomenological analysis was used in this qualitative study involving semi-structured interviews. General practitioners were included through snowball sampling

Results: Ten general practitioners were included, five men and five women. Seven themes were identified, intertwined to form two distinct cycles. The first cycle showed total commitment to the patient on the part of doctors who, faced with death and distress, felt a trying limitation. This limitation led to a feeling of failure, forcing the doctor to seek control. The second cycle showed the establishment of a unique relationship with the patient, evoking emotion in the doctor but also a positive feeling of usefulness and value.

Discussion: The total commitment of general practitioners corresponds to the ideal they impose on themselves. Faced with death and distress, this ideal is shaken. The doctor is tested and struggles with this experience. The establishment of a unique relationship with the patient counterbalances this negative experience. At this point, the doctor meets the patient in a unique human relationship. This relationship generates appropriate and reactive emotions in the doctor. The doctor is no longer experiencing hardship, but emotion. Ultimately, it is this relational commitment that gives meaning to the care of these patients, with a deep positive sense of usefulness, value and enjoy.

Conclusion: General practitioners are committed to their patients in distress in palliative care situations. This commitment generates a deep sense of usefulness and meaning when they manage to establish a unique human relationship with the patient.

ID 1172- Beyond the medical examination: from clinical touch to human connection – a qualitative study

Camille PERSAND

Université Sorbonne Paris Nord – Département De Médecine Générale, Le Raincy, France

Context: In a context where notions of body, intimacy and consent are gaining prominence, medical touch, although central to physical examination, is increasingly questioned. While the patient's experience has been widely studied, the perspective of general practitioners remains insufficiently explored.

Objectives: This study aimed to explore how they experience medical touch during consultations.

Methods: Qualitative study inspired by Grounded Theory, conducted among twelve general practitioners in the Île-de-France region, recruited through purposive sampling. Individual semi-structured interviews were recorded, transcribed and analysed through iterative open, axial and theoretical coding, with triangulation between multiple researchers.

Results: Medical touch appears as an adjusted, secure and co-constructed act, evolving from a technical gesture toward a humanizing interaction. It is perceived as a gesture of clinical rigor, a relational language of presence, and a practice framed by communication, consent and sociocultural norms, shaped over time by experience and continuity of care.

Discussion: Our findings suggest that medical touch, once perceived mainly as a clinical routine validating the physician's role, has evolved into a reflective, relational and ethical act. This shift mirrors societal changes regarding intimacy, consent and professional boundaries. Compared with the literature, our results move beyond Goffman's notion of touch as a social ritual reassuring the patient, and align more closely with contemporary perspectives. Laugier and Andrieu describe touch as an ethical mediation between two vulnerable subjects, which resonates with doctors' emphasis on transparency, consent and shared decision-making. Moreover, philosophers such as Merleau-Ponty and Serres highlight touch as a bodily language of presence and recognition a dimension strongly echoed by our participants, who see touch as a silent but meaningful mode of communication. Overall, medical touch appears as a multidimensional practice that combines technical skill, relational sensitivity and ethical responsibility. It embodies the transition from a paternalistic model toward a partnership-based doctor–patient relationship, where trust, consent and co-construction are central.

Conclusion: Medical touch emerges as a multidimensional skill technical, relational and ethical moving beyond examination to become a bodily language of care, reflecting a shift toward a trust-based partnership model in the doctor–patient relationship.

ID 928- Status of Taboos in Gynecological Health, Their Existence and Impact on Women's Access to Healthcare in France

Gal BENEDICTE, Elissa ROSSNET

Dumg Montpellier Nimes, Montpellier, France

Context: The concept of taboo, which emerged in the 18th century, is nowadays defined as 'that which is kept silent out of fear, modesty, or a system of religious prohibitions applied to what is considered sacred or impure.' Yet, 'it calls for silence even though its function is to speak.' This work focuses on taboos specifically related to gynecological health, as the practice of gynecology is becoming increasingly common among general practitioners.

Objectives: To determine whether or not French adult women perceive the existence of taboos surrounding their gynecological health, to identify what these taboo subjects are, and to assess their consequences on women's use of healthcare services

Methods: This is a descriptive, cross-sectional quantitative epidemiological study, conducted using an anonymous online self-questionnaire distributed via social media.

Results: More than one in two women consider that taboos exist regarding their gynecological health. Age, number of children, and marital status appear to influence the presence of taboos. Each of the topics mentioned is considered at least somewhat taboo, with those that seem to stand out the most being urinary incontinence, issues related to sexuality, and sexual violence. The impacts on healthcare-seeking behavior are mainly anxiety and apprehension at the idea of consulting a healthcare professional, but also hesitation and delay before seeking care.

Discussion: This quantitative work made it possible to address the topics we had initially considered as potentially taboo. Following an open-ended question on 'other taboos,' around twenty additional subjects emerged. It would be interesting to complement this study with qualitative research in order to ask women directly about what is taboo for them — but how can one inquire about what cannot be spoken?

Conclusion: Gynecological health taboos appear to be a reality for some women in France. It is essential for physicians to overcome their own taboos and to ask patients about these issues in order to improve women's healthcare. It could be worthwhile to distribute the questionnaire more widely to obtain a sample that is more representative of the entire French territory, and possibly to explore the situation among minors as well.

ID 732- Medical Humanities and Well-being of General Practitioners: A Comparative Inventory of Francophone Postgraduate Educational Initiatives

Jean-Charles VAUTHIER [(1)] , Monique AUBART [(2)], Jean-François MICHEL [(2)], Ingrid PAUR [(3)], Patrick TABOURING [(4)], Guy VIGNON [(4)], Nadia TABOURING [(5)], Cassian MINGUET [(6)]

(1) Degeresp-Faculté De Médecine, Nancy, France
(2) University Of Luxembourg, Luxembourg, Luxembourg
(3) Cirk, Wettingen, Suisse
(4) Cirk, Luxembourg, Luxembourg
(5) Cirk, Yverdon Lès Bains, Suisse
(6) Uc Louvain, Louvain La Neuve, Belgique

Context: General practitioners' well-being is crucial for the profession's sustainability. Previous work suggested that physician well-being depends on two key factors: optimized working conditions and a sense of meaning in practice. This relationship relies on medical humanities (philosophy, anthropology, arts, literature) fostering reflection, empathy, and resilience. Recent studies show their role in preventing burnout and strengthening professional identity. This project continues reflections from Dublin and Lisbon, with the conviction that physicians must learn to protect themselves from specific professional risks. To conduct a comparative inventory of medical humanities initiatives in Francophone postgraduate general practice training, identifying approaches, objectives, and perceived effects.

Methods: First, a review of postgraduate general practice curricula from Francophone universities in France, Belgium, Switzerland, and Luxembourg was conducted to identify courses related to medical humanities, including hours and teaching formats. Then, a short questionnaire was distributed to the same departments to identify objectives (reflection, empathy, professional posture, burnout prevention) and explore perceived impacts. The Francophone

scope ensures linguistic and pedagogical coherence while enabling meaningful comparison.

Originality: This work is original in its focus on postgraduate general practice training and its comparative approach across Francophone countries. It addresses a gap by linking medical humanities education to professional well-being, proposing a practical inventory

Lessons learned and future implication: A structured inventory will provide concrete examples of humanities-based initiatives and highlight best practices. These insights can inform curriculum design to strengthen resilience and empathy in future general practitioners. Ultimately, integrating h

Discussion: This work highlights the need for structured integration of humanities in GP training. Beyond listing initiatives, the challenge lies in translating these insights into actionable curricular reforms. Building networks among educators may foster innovation and mutual support, ensuring that future practitioners develop not only clinical expertise but also reflective capacity and resilience.

Conclusion: This inventory aims to foster collective reflection on teaching medical humanities to enrich GP training and support a more human, reflective, and fulfilling practice.

Corresponding author: Jean-Charles Vauthier, jean-charles.vauthier@univ-lorraine.fr

ID 38- Humanism in General Practice: a qualitative exploration of GPs' and bereaved informal caregivers' experiences of their relationship

Rébecca MEDOU

Université Clermont-Auvergne, Laboratoire Acceppt, Clermont-Ferrand, France

Context: The French Code of Medical Ethics emphasizes that doctors must support patients until death, maintain quality of life and dignity, and comfort loved ones. Support for informal caregivers begins before death and continues afterward, with bereavement support representing the final stage of the palliative care pathway. This ethical commitment reflects the humanistic foundations of general practice. At home, General Practitioners (GPs) play an essential role. However, no psychological study has yet explored caregivers' experiences of GP care and its effects on grief.

Objectives: The aim of this study is to identify the GPs' behaviors influencing the grieving process of bereaved informal caregivers, highlighting those perceived as beneficial.

Methods: This exploratory qualitative study was approved by an ethics committee in 2023 (IRB00013412, "CHU de Clermont Ferrand IRB #1", IRB number 2023-CF224). Participants included informal caregivers of patients receiving end-of-life care at home and GPs, recruited via social networks and snowball sampling. Semi-structured interviews were conducted in France in 2024-2025 by a psychologist and audio recorded. After transcription, data were analyzed using grounded theory, followed by analysis with the Alceste software. The recordings were subsequently deleted.

Results: Preliminary results are based on 11 interviews with bereaved informal caregivers and 6 with GPs. Caregivers supported spouses, children, or friends through diverse illness trajectories, including cancer, neurodegenerative diseases, and amyotrophic lateral sclerosis. Their described GPs' behaviors influencing grief, such as providing practical help, offering appropriate medical information, working in partnership, being present after death, showing sustained interest, and adopting a holistic approach. GPs report their practices, the obstacles they face, and their needs. Final results are expected by late 2025.

Discussion: While informal caregivers are often considered primarily vulnerable, this study suggests they also value being recognized as partners in care. These findings offer a novel humanistic perspective on GP –caregiver interactions and may inform primary care practice internationally, providing a basis for future cross-cultural research.

Conclusion: Ultimately, this study highlights the deeply human dimension of the care relationship at the end of life.

Inequity in Access to healthcare

ID 2191- Equity in Action: When Primary Health Care Gets Disability Assessment Right — Lessons from Nakuru, Kenya

Joy Karamana MUGAMBI [(1)] , Jonah MUASYA [(2)]

(1) Nakuru County Goverment & Kabarak University, Nakuru, Kenya
(2) Nakuru County Govermenty, Nakuru, Kenya

Context: Globally, disability affects over 1.3 billion people and is associated with poorer health outcomes, limited service access, and structural exclusion. The World Health Organization identifies disability inclusion as central to Universal Health Coverage and Primary Health Care (PHC), promoting integrated, people-centred services and hub-and-spoke models to bring specialist care closer to communities. Kenya's constitutional and policy frameworks align with this vision, recognising disability assessment and certification as statutory public services. However, in practice, assessment has remained facility-based, sequential, and medically oriented, resulting in delays, high costs, and attrition, especially in rural areas. In Nakuru County, these gaps prompted piloting a PHC-aligned, multidisciplinary outreach model to deliver integrated, end-to-end disability assessment.

Methods: Between October and December 2025, Nakuru County piloted a multidisciplinary PHC hub-and-spoke disability outreach across 13 sites in four sub-counties. Mobile community hubs enabled single-encounter medical, functional, and social assessment by integrated teams, supported by Community Health Promoters. Of 2,098 assessments, 1,670 were completed through outreach, compared with 428 routine facility-based assessments pending certification during parallel hospital-based service delivery period.

Originality: Innovatively, the model integrates end-to-end multidisciplinary disability assessment into PHC outreach, embedding community spokes and enabling direct comparison with routine facility-based services.

Lessons learned and future implication: Integrated multidisciplinary PHC assessments improved completion, equity, and access, but sustainability requires dedicated financing, appropriate infrastructure, advanced diagnostics, and planned workforce support to institutionalise community-based disa

Discussion: This experience demonstrates that community-anchored, multidisciplinary PHC disability assessment advances equity by reducing geographic, financial, and procedural barriers that disproportionately exclude persons with disabilities. Bringing assessment closer to communities improved completion, reduced caregiver burden, and enabled timely access to services. While system constraints persist, the model shows equity gains when disability assessment is treated as an integrated PHC function.

Conclusion: As health systems advance toward UHC through PHC, disability assessment must be integrated by design and financed sustainably. This case shows hub-and-spoke models improve equity. Embedding assessments within the Social Health Authority benefits package enables reimbursement, supports scale-up, and institutionalises inclusive disability services.

Corresponding author: Joy Karamana Mugambi, dr.mugambijoy@gmail.com

ID 2026- Perceived Health Effects of Racial Discrimination: A Qualitative Study in France

Sarraouinia GAKUNZI, Oceane YANG

Sorbonne Universite, Paris, France

Context: France ranks among European countries with the highest perceived racial discrimination (Defender of Rights, 2025). Individuals reporting discrimination are 1.9 times more likely to have poor health (INSEE, 2024), yet few studies explore their health experiences.

Objectives: To explore how individuals experiencing racial discrimination perceive their health, identify their coping strategies, and examine discrimination's effects on healthcare experiences.

Methods: Phenomenological qualitative study. Population: 12 participants (11 women, 1 man, mean age 33 years), recruited via social media, self-reporting racial discrimination. Semi-structured interviews (average duration: 47 minutes) conducted between December 2023 and February 2024, audio-recorded and transcribed. Analysis: Interpretive phenomenological approach with experiential labeling, data triangulation by two researchers. Approval from the CNGE Ethics Committee, GDPR compliance, informed consent obtained.

Results: Participants described persistent hypervigilance, sleep disturbances, and anxiety, directly attributing these to repeated experiences of racial discrimination. Many reported intrusive memories of discriminatory events and a pervasive sense of alertness across professional, social, and healthcare settings. Coping strategies included self-censorship, overperformance to counter negative stereotypes, and linguistic or vestimentary adjustments to mitigate racial bias, all of which contributed to chronic psychological fatigue and emotional exhaustion. While most reported good physical health, some associated somatic symptoms like chronic pain or digestive issues with prolonged stress.

Discussion: Findings align with racial trauma theory (Carter, 2007), where chronic discrimination acts as a stressor causing psychological distress. The stereotype threat (Ka-Sy, 2013) and racial burden (Soumahoro, 2020) were evident in coping strategies like overperformance, reflecting the emotional labor of navigating bias. Distrust in healthcare mirrors studies showing racial biases in diagnosis and pain management (Benard, 2023; Fau, 2021). Preference for racialized physicians highlights the need for culturally concordant care (Saha et al., 1999). The link between stress and physical symptoms (e.g., fibromyalgia) supports frameworks of embodied inequality (Krieger, 2005), though the young sample (mean age 33) may limit physical health findings.

Conclusion: Racial discrimination significantly affects perceived health, particularly mental well-being, and undermines trust in healthcare. Patient-centered approaches and provider training on unconscious bias are critical to address these inequities. Further research should explore long-term physical health effects and scalable interventions.

Corresponding author: Oceane Yang, yang.oceane@gmail.com

ID 1638- Shared community-hospital position in the Paris region in France: a scheme for the most precarious patients

Jeanne VILLENEUVE

General Medicine Department, Sorbonne University, F75012, Paris, France, Paris, France

Context: The French healthcare system should guarantee accessible, effective healthcare for all, regardless of their social level. This system is currently facing numerous challenges and the structural fragmentation between community-based general practice and hospital care contributes to difficulties in health system navigation for service users, disproportionately affecting populations facing the greatest barriers to care. As part of the creation of shared community-hospital positions, several general practitioners (GPs) split their time between a multidisciplinary healthcare center (HCC) and a public hospital in Paris.

Objectives: The objectives of this study were to assess the socio-demographic characteristics of patients managed at the HCC as part of this scheme and the factors associated with this management.

Methods: Two physicians working part-time at the public hospital and part-time at the HCC saw patients who were not registered with a GP, referred by other hospital departments, in an inpatient assessment consultation. The aim was to set up a community-based follow-up within a HCC located near the hospital, where the same physicians would practice as GPs. Patients were included between November 2018 and November 2022. A retrospective, descriptive and analytical study of the medical files was conducted, with collection of the patients' medical and social data.

Results: Of 1,175 eligible patients, 725 were managed at the HCC. Patients starting to be followed at the HCC were significantly more likely to benefit from a state social protection scheme, reflecting a precarious social situation. The adjusted odds ratio was 2.13 [1.29-3.45] for the social protection of people in an irregular situation and

1.82 [1.16-2.78] for the means-tested social protection.

Discussion: This study was the first French study to assess the shared community-hospital position scheme. The large sample size allowed obtaining robust results in the multivariate analyzes.This study showed the importance of this innovative scheme for access to primary care for precarious patients, and the benefits of the collaboration between community medicine and hospitals.

Conclusion: This innovative scheme, connecting the community and the hospital, attractive to physicians and ultimately allowing a more integrated healthcare system shows its relevance and needs to be financed and sustained, along with the implementation of measures with social and medico-economic impacts.

Corresponding author: Jeanne Villeneuve, jeanne.villeneuve@richerand.fr

ID 1598- Co-constructing a health autonomy evaluation tool for socially vulnerable adults: a participatory study using Nominal Group and Think Aloud Methods

Lisa OUANHNON [(1)] , Earvin CARLOT [(1)], Marie DONIUS [(2)], Karine PARIENTE [(2)]

(1) Dumg Toulouse, Toulouse, France
(2) Service De Médecine Sociale Et Santé Sexuelle Duchu De Toulouse, Toulouse, France

Context: People experiencing social vulnerability face major barriers to healthcare access, and fragmented care pathways. Strengthening patients' autonomy in health is essential in reducing social health inequalities. *** is a multidisciplinary care-coordination and patient-support programme implemented in * to assist adults experiencing social vulnerability and chronic conditions in acquiring autonomy in health. Given the diversity of user profiles and the multi-level nature of its interventions, no existing standardised tool can adequately capture the multifaceted benefits of e.CARE's accompaniment.

Objectives: To develop a co-constructed evaluation tool measuring the level of health autonomy among adults experiencing social vulnerability.

Methods: We used an innovative participatory design combining two qualitative approaches. (1) Nominal Group Technique—a structured consensus method—with health and social care professionals to generate, clarify, and prioritise evaluation items. (2) Think Aloud individual interviews with service users to assess item comprehension, identify ambiguities, and refine wording. Data were analysed thematically and triangulated to produce a consensual, user-validated tool.

Results: From 46 initial propositions, 22 were clarified, and 15 priority items were selected during the Nominal Group session. Think Aloud interviews revealed lexical barriers and the importance of concrete, accessible language. Based on user feedback, several items were reformulated or merged. The final tool comprises 13 items, capturing three interconnected dimensions: • Health literacy (understanding illness, treatment, rights) • Empowerment (self-efficacy, decision-making, perceived respect) • Navigation of the healthcare system (booking appointments, anticipating renewals, planning care).

Discussion: The participatory design is a major strength, combining a structured consensus method with direct user feedback to ensure relevance and acceptability. The small number of service users included in the Think Aloud phase remains a limitation. Importantly, completing the grid requires human accompaniment, as it fosters dialogue, clarifies misunderstandings, and supports users with low literacy. This co-constructed tool offers a promising way to document changes in health autonomy and to evaluate the contribution of programmes such as e.CARE.

Conclusion: This co-constructed tool, adapted for primary care, provides a practical way to assess health autonomy among vulnerable adults. Future work is needed to evaluate its acceptability and feasibility across diverse programmes supporting people in situations of social vulnerability.

ID 1423- Caring behind walls: a qualitative ethnographic study of primary care practice in Belgian closed detention centers.

Naajiyah KATHRADA

Camg, Uclouvain, Brussels, Belgique

Context: In XXX, closed detention centres are administrative facilities for people with irregular migration status. Although not part of the penal system, they operate through carceral logics : surveillance, restricted movement, and institutional opacity. General practitioners (GPs) occasionally intervene in these settings despite the absence of a defined first-line mandate. The clinical encounter thus unfolds at the intersection of healthcare, migration control, and structural vulnerability.

Objectives: To explore and analyse how GPs and other external caregivers experience, understand and navigate the ethical, practical and emotional tensions involved in providing care within XXX closed centres.

Methods: A qualitative, inductive approach grounded in the principles of in-home or insider ethnography. Fieldwork consisted of five visits to closed centres between May 2023 and May 2025 during voluntary GP missions. Data sources included a field journal, observation of clinical encounters and institutional routines, a recorded multidisciplinary focus group (GPs, psychologists, psychiatrists, lawyers), and documentary analysis. A reflexive thematic analysis was conducted.

Results: Six major tensions emerged. Practitioners described an emotional shock linked to the carceral environment and detainees' distress. External GPs occupied an ambiguous position, moving between caregiver, evaluator and witness to institutional violence. Material and organisational constraints (limited access, scarce equipment, reduced confidentiality) strained the therapeutic relationship. Practitioners adopted adaptive strategies such as relational caution and selective engagement. Small acts of care served as micro-resistances that helped preserve a sense of ethical agency.

Discussion: These tensions reflect structural effects of a system oriented toward surveillance rather than care. Institutional configurations reshape the therapeutic relationship, constrain clinical judgment, and fragment the GP's role. Closed centres create a significant "ethical burden" and the study highlights how context can fundamentally alter core principles of primary care such as continuity, confidentiality, and patient-centredness.

Conclusion: Providing care in closed centres exposes GPs to significant ethical and emotional challenges. These results highlight the need for clearer institutional frameworks, specialised training on detention health and broader debate on the limits of healthcare within migration enforcement systems. Beyond clinical implications, this study also contributes to medical anthropology by documenting how institutional settings shape moral experience, professional identity and the possibilities of care within coercive environments.

ID 567- Underreporting of Occupational Diseases among Farmers: General Practitioners' Perspectives in Northern XXX

Margaux BRIOLET

Faculty Of Medicine, University Of Rennes, Rennes, France

Context: Underrecognition of occupational diseases is a multifactorial phenomenon, beginning with insufficient reporting. Farmers are particularly vulnerable to health inequalities notably due to their specific relationship with healthcare. For them, the general practitioner is often the first and only point of contact, including for occupational health issues. This study explores the factors contributing to the underreporting of occupational diseases encountered by general practitioners (GPs) in their care of farmers.

Objectives: To identify the barriers perceived by general practitioners to the reporting of occupational diseases among farmers.

Methods: A self-administered questionnaire was distributed to general practitioners working in rural or semi-rural areas within the five Territorial Professional Health Communities (CPTS) of northern XXX, excluding the urban areas of XXX and XXX. Data collection took place from October 2024 to May 2025. Descriptive analysis of frequencies and percentages was performed.

Results: Forty-five physicians participated, and thirty-eight questionnaires were included in the analysis. None of the respondents had received continuing medical education related to farmers' occupational health within the past five years. 63.2% felt able to answer occupational health questions from their farming patients. 39.5% had never issued an Initial Medical Certificate (CMI) for an occupational disease. The most frequently reported obstacle was the existence of other possible etiological factors (81.6%), while the most limiting barrier was the lack of knowledge of the official occupational disease tables and their criteria. 86.8% of participants reported being unaware of the role of the Regional Committees for the Recognition of Occupational Diseases (CRRMP)

Discussion: Findings highlight a significant lack of training and resources among GPs regarding agricultural occupational health. Combined with regulatory complexity, this lack of means contributes to persistent underreporting, despite GPs' central role in identifying potential occupational diseases.

Conclusion: Although general practitioners are on the front line for farmers' occupational health, they are not adequately equipped for this responsibility. Strengthening both initial and continuing education, improving collaborative and surveillance mechanisms, and developing practical consultation tools are key to enhancing recognition of occupational diseases in the agricultural sector.

ID 261- Care Pathways of underserved Patients: A Qualitative Study Exploring Factors Influencing Patients' Choice of Secondary Care Providers

Mathilde MINET, Lucie BONNEFOY

Dumg Montpellier, 48000, Mende, France

Context: The availability of specialist care is limited in underserved areas, like in the department of Lozère. Patients are compelled to seek consultations outside of Lozère, and sometimes they forego care altogether.

Objectives: This study aims to explore the factors that influence patients in underserved areas (example: Lozère) in their choice of specialist healthcare professional within their care pathway.

Methods: This is a qualitative study. A thematic analysis was conducted based on semi-structured individual interviews with patients from Lozère, carried out from May 2023 to November 2024. The sampling was purposive with maximum variation. Triangulation of the analysis allowed for the identification of 7 themes and the achievement of data saturation after 10 interviews.

Results: The factors influencing a patient's choice are trust, the central role of the treating physician, the practitioner's reputation, the patient's self-management skills, and the anticipation of their specific needs. There is a limitation of available alternatives and a lack of knowledge about the healthcare options to make a choice.

Discussion: The choice of specialist physician is multifactorial and complex. The results highlight the need to improve information and access to specialist care in Lozère. The study emphasizes the importance of a patient-centered approach, while taking into account local specificities and the challenges related to medical desertification.

Conclusion: Choosing a secondary care professional for a patient involves various determining factors. A patient-centered approach with AI assistance could help patients choose their practitioner.

Inequity in Access to healthcare

ID 2204- Chronically ill patients receiving ongoing care at the West French Guyana Hospital Centre are being referred to private general practitioners.

Camille OBERT-MARBY [(1)] , Eva TIREAU [(2)], Michèle GOLDZAK [(3)]

(1) Faculté De Médecine Maieutique Et Sciences De La Santé, Lille, France
(2) Faculté De Médecine Hyacinthe Bastaraud, Pointe À Pitre, France
(3) Faculté De Médecine Hyacinthe Bastaraud, Saint Laurent Du Maroni, France

Context: In a territory subject to low healthcare provision, high migration and great precariousness, renunciation of healthcare among precarious populations is frequent. The reorientation of these patients in an adapted care pathway in (XXX) is confronted with the test of their reality of life, coming up against elements going beyond the presence or not of social coverage.

Objectives: To understand and explore how chronically ill people in (xxx) feel about and experience their care in private practice, after opening up social rights.

Methods: Qualitative survey by semi-directed interviews at the Permanent Access to Health Care (PASS) of the (xxx) Hospital Center. The patients included had a known chronic illness previously treated by the PASS service, and had been redirected by the latter into the common rights system via a medical letter, after opening up social rights.

Results: Fourteen patients were interviewed. Without social rights, access to care is possible, but the patient's ability to take action is limited, both administratively and logistically. The presence of caregivers becomes essential. The PASS favors access for all, and is sometimes seen as an obligatory temporary stop-off point in their care pathway. Here, patients strengthen or acquire a desire for regular care and follow-up. Once redirected into the mainstream system, they find themselves in a proactive position, giving themselves the means to manage their illness. The General practitioner's role as coordinator is established, and the quality of the doctor-patient relationship is paramount. His role thus goes beyond that of prescribing medication, propelling him to the status of overall referent, with the task of reducing the obstacles inherent in each patient's care pathway.

Discussion: The care pathway for precarious populations in (xxx) is fraught with logistical and administrative difficulties. The hospital-city link, via the PASS service, appears to be a pivotal period for efficient disease management. The presence of caregivers and the therapeutic relationship are key elements for precarious populations suffering from chronic pathologies.

Conclusion: The development of an adapted transport network, local administrative assistance and therapeutic education networks should be worked on. Finally, it would be interesting to explore the experience of private practitioners regarding the care of these patients.

ID 1504- Mediterranean Syndrome : GP residents' beliefs and narratives about a racial prejudice

Célie COUDORO, Sarraouinia GAKUNZI

Sorbonne Université, Paris, France

Context: The chain of stigma - categorisation → stereotypes → prejudice → discrimination - runs throughout society, and healthcare professionals are no exception. Medical professionals often mirror public representations, which can lead to unequal care. Cognitive biases contribute to social health inequalities through discriminatory refusals or differentiated treatment. The "Mediterranean syndrome", labeled a discriminatory stereotype by the French Defender of Rights, is often informally invoked in clinical practice. This study investigates how GP residents perceive and learn about this term.

Objectives: To explore the representations of general practice residents at Sorbonne University regarding the Mediterranean syndrome.

Methods: A qualitative study inspired by grounded theory was conducted using semi-structured interviews and verbal association techniques. Participants were first to third-year GP residents at Sorbonne University.

Results: Ten residents participated in interviews, and 46 took part in the verbal association phase. Residents perceived the Mediterranean syndrome as a vague concept, informally transmitted among peers. It appeared to function as a protective mechanism against addressing racism and medical bias, particularly in challenging or complex care situations. Participants oscillated between criticism, justification, and resignation, reflecting the tension between the ideal of medical neutrality, hierarchical constraints, and the persistence of stereotypes through professional socialisation.

Discussion: The pseudo-scientific framing of the Mediterranean syndrome contributes to its persistence, giving the illusion of a medical category while legitimising racial prejudice. Often described as an urban legend, it illustrates how stereotypes are transmitted within medical culture, particularly in contexts of clinical uncertainty. Findings highlight the need to teach students to tolerate uncertainty, reinforce patient-centered care, increase awareness of historical roots of racial bias, and address power dynamics in clinical training to foster reflective practice.

Conclusion: Residents' representations reveal the persistence of stereotypes in medical education and difficulty managing uncertainty and critical thinking, constrained by the ideal of neutrality. A threefold approach - recognising limitations, deepening knowledge, and remaining vigilant against discrimination -can promote a fairer, more reflective, and humane medicine. Keywords: general practice, residents, bias, discrimination, racism, health

ID 650- Ressenti et vécu du consentement aux soins chez les personnes en situation de grande précarité

Bertille TERNAT GUIBOURGÉ, Florence ADELINE-DUFLOT, Mathilde BESSELIÈVRE, Alice TORNO, Virginie MIGEOT, Pierre-Edouard BLONDEL

Rennes, Rennes, France

Context: Les personnes en situation de grande précarité vivent régulièrement des situations de non recours ou de renoncement aux soins pour de multiples raisons. Dans ce contexte, quel est le vécu et le ressenti du consentement aux soins chez les personnes en situation de grande précarité ?

Objectives: Cette étude avait pour objectif d'explorer le ressenti et le vécu des patients francophones en situation de grande précarité concernant l'information donnée sur leur santé et leurs soins, ainsi que leur accès au consentement aux soins.

Methods: Une étude qualitative par entretiens individuels semi-dirigés a été réalisée auprès de personnes en situation de grande précarité fréquentant des accueils de jour associatifs à XXX. L'analyse des données a été menée selon une méthode phénoménologique interprétative, avec une triangulation des données. Un schéma modélisant les données a été réalisé.

Results: Douze entretiens ont été réalisés entre janvier et avril 2025. L'analyse des résultats a mis en évidence l'impact des expériences antérieures de soins non consentis, les qualités attendues du soignant, les responsabilités ressenties par les participants dans la construction de la relation de confiance dans les soins. La notion de consentement aux soins semblait moins essentielle que le respect de la dignité reconnaissant l'expertise du patient, respectant son corps et intimité, accueillant avec bienveillance sa situation sociale. La majorité des participants mettait en avant la notion de discrimination dans les soins en lien avec leur situation sociale.

Discussion: Les attentes des participants concernant la relation soignante étaient similaires à celles de la population générale retrouvées dans la littérature. Des particularités en lien avec la situation sociale des participants ressortaient comme un rapport au corps particulier et l'assimilation des soignant aux autres représentants de la société. La notion de consentement sous forme de processus comme décrit dans la littérature

aujourd'hui semblait plus proche de la définition des participants.

Conclusion: Il serait intéressant d'étudier les représentations des soignants envers les patients en situation de grande précarité en vue d'améliorer la formation des soignants. Il pourrait également être intéressant de questionner les soignants sur la notion de dignité dans les soins et les manières de questionner et respecter la dignité de chaque patient.

Corresponding author: Bertille Ternat Guibourgé, bertille.ternat@hotmail.com

ID 624- Association between patients' socio-professional group and additional diagnostic tests prescription in general practice: analysis of the R2IMG database

Caroline ALBERTINI, Elise ARCHER, Théo DUGUET

Sorbonne Université, Paris, France

Context: Social inequalities in health (SIH) are associated with poorer health outcomes. While many studies have examined this issue, no recent XXX study has investigated a potential association between SIH and possible under- or over-prescription of diagnostic tests in certain socio-professional groups (SPG).

Objectives: The primary objective was to assess the association between the number of diagnostic tests prescribed per general practice consultation and patients' SPG.

Methods: An observational, multicenter, cross-sectional study was conducted using the XXX general practice consultations database. Consultations of non-retired adult patients for whom the profession was specified were included. SPG was used as a socioeconomic marker, grouped into three categories (advantaged – aSPG, intermediate – iSPG, and disadvantaged – dSPG). The primary outcome was the comparison of the mean number of tests prescribed per consultation by SPG. Secondary outcomes focused on the proportion of consultations with at least one test prescribed and on the analysis by test type. Descriptive and comparative analysis (Chi-square, Fisher's exact test, ANOVA) were performed, followed by multivariate logistic regression.

Results: Of the 951 consultations in the database, 340 met the inclusion criteria. On average, 0,50 test were prescribed per consultation in aSPG, 0,40 in iSPG, and 0,51 in dSPG (p = 0,38). At least one test was prescribed in 31,01% of consultations in aSPG, 32,56% in iSPG and 36,43% in dSPG (p = 0,80). After adjustement, no significant association was found : compared with dSPG, the prescription-rate OR was 0,87 [0,48-1,58] for iSPG and 0,80 [0,43-1,48] for aSPG.

Discussion: Our study did not find a significant difference in the number of tests prescribed based on SPG, which is consistent with European litterature but differs from American studies. The influence of the social protection system could explain these results. The data analyzed reflect diverse practices, but the sample size was limited by missing data. A study examining differences across successive consultations and accouting for health status severity would be valuable.

Conclusion: In light of social inequalities in health and their consequences, it remains important to pursue research on this topic and to promote mechanisms that ensure equitable access to healthcare for all patients.

Corresponding author: Caroline Albertini, carolinejulie.albertini@gmail.com

ID 353- Patients affected by racism and social inequalities in health: a scoping review

Frederic ZORZI, Lisa ADJEROUD, Justine MASSON

Université Claude Bernard Lyon 1, Lyon, France

Context: Social inequalities in health are a determinant of health. In English-language literature, racism is described as a social inequality in health. Being a victim of racism is a cardiovascular, metabolic and psychiatric risk factor. In France, the current legislative framework prohibits the collection of ethnic data in the field of health, in an

effort to protect against discrimination. This prohibition makes it difficult to document social inequalities in health linked to racism. Surveys such as TeO and TeO2 provide indirect indicators, without allowing for an in-depth analysis of the effects of structural racism on the health of populations. This statistical invisibility limits the possibilities for research, evaluation and action in public health.

Objectives: Explore how racism is conceptualised and analysed as a social health inequality in French-language scientific literature.

Methods: Scoping review exploring the MEDLINE-PubMed, Cairn and LiSSa databases according to PRISMA-SCR recommendations

Results: The search equations found 3,965 articles. After the selection process, 11 articles were chosen for review. Of these, two were from Quebec and nine were from France. The selected publications included six author opinions in the form of literary essays, an analysis of French literature, a comparative essay between France and the United States, a quantitative multiple regression study conducted in France, a qualitative study, and a descriptive French study.

Discussion: This scoping review found that French-language scientific literature addresses racism as a factor in social inequalities in health to a limited extent. The few available publications are predominantly feature authors' opinions. The results of this review suggest that incorporating an intersectional approach, taking into account the intertwining of ethno-racial discrimination, gender, socio-economic status and other social determinants, would allow for a better understanding of the mechanisms underlying social inequalities in health. This approach explores the power relations or structural contexts in which risk factors occur. Intersectionality provides a critical analytical framework for revealing the blind spots of conventional research.

Conclusion: An intersectional approach is compatible with the principles of person-centred general practice and could contribute to the development of primary care research, enabling more appropriate and equitable patient care and fostering more inclusive public health policies.

ID 253- Career paths of general practitioners practising in City Policy Priority Neighborhoods in Seine-Saint-Denis (France)

Anne MOTTAIS, Roman MARTINS LOPES

Dumg Uspn, Bobigny, France

Context: Seine-Saint-Denis is one of France's most precarious departements, with a lower medical demography than its neighbouring departments. There are few factors that encourage GPs to set up practice here. Despite this, some GPs decide to practice here.

Objectives: The aim of this study was to retrace the career paths of GPs who practice or have practiced in Seine-Saint-Denis' priority urban districts.

Methods: A qualitative study inspired by biographical research was carried out with 11 general practitioners. The interviews and their analysis were triangulated by two researchers. Diagrams tracing each individual's career path, any turning points or periods of continuity were produced.

Results: Various factors appeared to influence the career paths of the GPs interviewed. The main one was being from the département. Other factors, related to primary and secondary socialisations, also played a role, notably family, friends, the type or mode of practice structure, and university practice. Most of the doctors' careers in the study were marked by an awareness of the social health inequalities affecting the population of Seine-Saint-Denis. For most, this awareness was accompanied by a commitment to activism and/or associations. The complexity of practice in Seine-Saint-Denis was mainly due to the many medical and social problems faced by patients, and to the language barrier. In order to maintain their practice in Seine-Saint-Denis, despite this complexity, practitioners were considering adaptations in the future, notably by diversifying their practice or creating their own practice structure.

Discussion: Three different career paths were highlighted by this research, and these paths and

profiles are found in the literature. The profile of several doctors interviewed was linked to the concept of social medicine, also identified in the literature. The originality of this work lies in highlighting the importance of the territory of origin as well as the primary and secondary socialisation of GPs in their respective paths.

Conclusion: This study has highlighted several characteristics of the career paths of GPs practicing in priority urban districts in Seine-Saint-Denis. Being from the department of Seine-Saint-Denis and having an awareness of social inequalities in health seem to have a particular influence on the career paths of GPs practicing in the area.

ID 43- Gouvernance hospitalière et IA clinique en Côte d'Ivoire : vers une régulation éthique des pratiques médicales augmentées

Keumian DAGUI

Université Alassane Ouattara, Evry-Courcouronnes, Côte d'Ivoire

Context: L'accès équitable aux soins de santé primaires est un enjeu central de santé publique dans de nombreux pays. En France comme en Côte d'Ivoire, le territoire de résidence influence fortement la possibilité de recevoir des soins en temps utile et de qualité. Le code postal devient ainsi un indicateur social et sanitaire à part entière, révélateur d'inégalités systémiques dans l'organisation des soins.

Methods: Ce travail repose sur une approche comparative, nourrie par des expériences cliniques de terrain en médecine générale dans deux contextes géographiques : une zone rurale sous-dotée en France, et une zone périurbaine en Côte d'Ivoire. L'analyse qualitative s'appuie sur l'observation de situations concrètes de patients confrontés à des difficultés d'accès aux soins, croisées avec une revue succincte de données contextuelles et démographiques.

Originality: La perspective croisée Nord-Sud apporte un éclairage original sur les mécanismes communs et spécifiques des inégalités d'accès. Malgré des différences structurelles majeures entre les deux pays, des points de convergence apparaissent : concentration des r

Lessons learned and future implication: Des stratégies locales émergent dans les deux contextes : développement de la télémédecine, mobilisation communautaire, organisation de consultations mobiles, travail interprofessionnel. Ces initiatives montrent l'importance d'adapter les réponses aux réa

Discussion: L'accès aux soins ne peut être pensé indépendamment du territoire et des inégalités socioéconomiques qui s'y attachent. La médecine générale, en tant que porte d'entrée du système de santé, a un rôle clé à jouer pour identifier, alerter et agir contre ces disparités. Cela suppose une reconnaissance politique et institutionnelle de cette fonction sociale du soin.

Conclusion: Garantir un accès équitable aux soins primaires, quel que soit le code postal, est un enjeu éthique et sanitaire universel. Il exige une approche territoriale, participative et centrée sur les réalités de chaque population.

ID 1831- Patients on neuroleptics: the role of the IPA in the MSP

Eva COSTES [(1)] , Jean-Christophe POUTRAIN [(2)]

(1) Msp Mont Royal Santé, Montréjeau, France
(2) Dumg Toulouse, Montréjeau, France

Context: Patients with psychiatric disorders are exposed to cardio-metabolic complications when treated with second-generation neuroleptics. How can IPA in MSP improve prevention and identification of cardiovascular risk factors in such patients ?

Objectives: Main objective: to evaluate the application of the ANSM recommendations and hygienic and dietary rules in patients treated with second-generation neuroleptics followed by the IPA in MSP. Secondary objective: to compare the care of

patients exclusively followed by the general practitioner with the joint follow-up with the IPA, in order to measure the contribution of IPA work.

Methods: Multicenter retrospective observational study from January to December 2024 via WEDA software. Two groups compared: patients followed by the general practitioner alone (GP) and those followed by the GP/IPA duo in two MSPs. The presence or absence of: sex, age, weight, BMI, umbilical circumference, blood glucose, lipid profile, blood pressure, tobacco, alcohol, illicit substances were recorded Inclusion criteria: adult patients, patients falling within the scope of the IPA treated with second-generation neuroleptics. Comparisons of the data from the GP and GP/IPA groups were performed with a chi-2 assay with the biostatTGV software.

Results: 103 cases were reviewed. 41 were followed by GPs/IPAs. There is an increase in the number of items recorded by IPAs in the files compared to the activity of the GPs. For weight, blood sugar and lipid profile, this increase is statistically significant.

Discussion: IPAs know and apply medical recommendations. Their work improves record-keeping in primary care. As indicated in the international literature, the GP/IPA dyad reinforces the quality of follow-up in primary care. Strengths: Poorly studied population, data from real practice, enhancement of the role of the IPA. Limitations: Few IPAs working in primary care, retrospective study, recommendations dating from 2010. Opening: Creation of a consultation grid for the IPA. It could be subject to later validation.

Conclusion: Collaboration between professionals in MSPs, particularly between GPs and IPAs, can improve the health of these patients.

ID 1554- Preventing falls among the elderly: an initiative in a multi-professional health center in Paris's 14th arrondissement

Sophie BERNARD, Marc EL KOMOS

Université Paris Cité, Paris, France

Context: The XXX population is aging. In 2020, people over 65 represented 20,5% of the population, compared to 19,7% in 2018. By 2040, one in four persons in four will be over 65. One in three people over the age of 65 falls each year, resulting in more than 9300 deaths. This morbidity and mortality rate inspired the team of the XXX multi-professional health center (MHC) in XXX t to look at this issue. The goal was to reduce falls among older adults by addressing modifiable risk factors.

Methods: The target audience was patients over the age of 70 consulting at the MHC in XXX. We conducted an information campaign to the target audience consulting at the MHC the opportunity to make an appointment for a general medical consultation dedicated to the risk of falls. The assessment was carried out using a questionnaire completed with the physician covering nutritional status, physical activity, walking, rapid cognitive assessment, environmental assessment, and prescription review. A satisfaction questionnaire was then given to the patient. The analysis of the results focused on the number of flyers distributed, the number of consultations carried out, and the satisfaction questionnaire.

Originality: The intervention made it possible to offer general medical consultations dedicated to the prevention of falls to these elderly patients.

Lessons learned and future implication: We realized 13 dedicated consultations between October and November 2024. 70% of patients had never discussed the risks of falls with a healthcare professional. One-third of patients were offered a change in their prescription, 80% specialized care, and 7

Discussion: The main strength was the implementation of personalized actions. The main issue is recruitment bias, as it didn't include patients who were being treated at home.

Conclusion: Falls are associated with considerable morbidity and mortality. Our MHC is part of a prevention initiative aimed at the local population through dedicated consultations, highlighting that the subject is rarely discussed even though action can be taken.

ID 1251- Collaborations Between General Practitioners and Other Health Professionals: Trends and Territorial Disparities

Thomas HERAULT [(1)] , Marie Christine BOURNOT [(2)], Marie Astrid METTEN [(2)], Sandrine DAVID [(2)], Anne Marie LADEVEZE-CAYLA [(1)], Jean François BUYCK [(2)]

(1) Urml Pays De La Loire, Nantes, France
(2) Ors Pays De La Loire, Nantes, France

Context: A series of panel surveys conducted among representative samples of self-employed general practitioners has been carried out in different regions of YYY, since the mid-2000s. Its aim is to shed light on the practices, working conditions, and opinions of these professionals, as well as their evolution and the existence of territorial specificities.

Objectives: The aim of this survey was to explore interprofessional collaborations: the frequency and content of exchanges with colleagues specialized in general practice or other medical disciplines, and with other health professionals.

Methods: A total of 1,550 practitioners in YYY, including 300 in the XXX region, were surveyed on this topic in 2022. Data collection was conducted online (self-administered questionnaire) or by telephone. Analyses accounted for the sampling design (complex stratification) and non-response adjustment.

Results: In 2022, nurses were the health professionals with whom general practitioners in the XXX region most frequently exchanged information: 68% reported sharing medical information with them at least once a week or daily; 58% exchanged with other general practitioners, 57% with pharmacists, 54% with physicians from other specialties, and 17% with physiotherapists.

Discussion: Compared to a similar survey conducted fifteen years earlier, the proportions of practitioners regularly exchanging with general practitioner colleagues and with nurses have increased significantly, while those related to exchanges with specialists and pharmacists remained stable. Moreover, general practitioners in the XXX region differ from their counterparts in other regions by engaging in more frequent exchanges with other physicians (organization of appointments or hospital admissions, or when seeking opinions on diagnoses or patient management).

Conclusion: These results highlight changes and territorial disparities in interprofessional collaboration practices. They can be linked to both local and national organizational changes within the healthcare system, as well as to evolving population needs.

ID 407- Pharmaceutical interventions in self-medication, focus on referrals for consultation: a descriptive study in community pharmacies

Sabrina BEDHOMME [(1)] , Elodie MARTINET [(1)], Typhène ROCHOUX [(1)], Céline LAMBERT [(2)], Elodie LAFARGE [(1)], Bénédicte PERETON [(1)], Chantal SAVANOVITCH [(1)]

(1) Clermont Auvergne University, Clermont-Ferrand, France
(2) Drci Chru Clermont-Ferrand, Clermont-Ferrand, France

Context: The dispensing pharmacist plays a pivotal role in patient's care. Its main mission is to secure and optimize the dispensing act. In this context, the pharmacist may be required to carry out a pharmaceutical intervention (PI), which is defined as "a proposal for a modification of the therapy made at the initiative of the pharmacist, […]". In cases where the pharmacist observes that the limit of the pharmacy advice has been reached, the patient has a "reinforced obligation" to refer to a qualified practitioner. Consequently, he carries out a PI and assumes responsibility for the guidance.

Objectives: The objective of this study is to describe the characteristics of the orientation when the pharmaceutical intervention resulted in a referral to another health professional.

Methods: This is a cross-sectional descriptive study of Pharmaceutical Interventions (PIs) in self-medication. The PIs were collected in 201 dispensing pharmacies (2017 – 2024).

Results: 978 PIs in self-medication led to referral to consultation. With regard to the practitioner to whom the patient is referred, the majority of cases are attributable to general practitioners (n = 740; 75.7%), dentist (n=140; 14.3%) or to emergency department (n=53; 5.4%) Referral to a physician was mainly proposed for pain (n=210; 26.9%). The primary reason for referral was identified as the necessity for a clinical examination (n=512; 65.5%). With regard to the consultation period recommended by the provider, consultations of an urgent nature pertained to 9.4% (n=92) of PIs.

Discussion: General practitioners were the primary health professionals targeted, which is consistent with the fact that they can refer patients to a specialist when necessary. Although representing a minority, referral to emergency consultations indicated a tendency for patients to attend pharmacies for critical cases. A concrete example of this phenomenon is the presence of ocular complaints, which are often underestimated by patients.

Conclusion: Detecting emergency criteria or need for diagnosis or medical act, the pharmacist plays an important role in guiding the patient through the healthcare system in a context of tension in access to care. In doing so, it improves patient care by avoiding a delay in diagnosis or the occurrence of adverse effects.

Corresponding author: Sabrina Bedhomme, sabrina.bedhomme@uca.fr

ID 740- General practitioners' referral practices for patients with upper limb and spinal musculoskeletal disorders

Clara VILLEPONTOUX [(1)] , Aurélie TOMEZZOLI [(2)]

(1) Département De Médecine Générale De La Faculté De Médecine, Campus Santé, Université De Rennes, 35043 Rennes Cedex, Rennes, France
(2) Société De Formation Thérapeutique Du Généraliste (sftg) Recherche, Paris, France / Univ Rennes, Inria, Cnrs, Irisa-Umr 6074, 35000, Rennes, France, Paris / Rennes, France

Context: Musculoskeletal disorders (MSDs) represent 20.6% of general practitioner (GP) consultations. However, GP' referral practices has been scarcely documented.

Objectives: To describe and analyse GPs' referral practices, regarding upper limb and spinal MSDs.

Methods: This cross-sectional survey was conducted among private GPs' practices between June and September 2025. GPs were asked to complete an online questionnaire about their last patient aged 18 or over, who consulted for MSD symptoms. The questionnaire focused on upper-limb MSDs for GPs who completed they thesis in an odd-numbered year, and on spinal MSDs otherwise. Analyses were performed using R. This study was approved by the Ethics Committee of Rennes University Hospital (no. 25.50).

Results: A total of 197 patient records (110 women, 87 men, aged 49.4 ± 13.7 years) were analysed; 41% described upper limb and 59% spinal MSDs. At least one referral was mentioned in 91% of records, among witch 91% concerned a paramedical professional, 54% a medical doctor, and 13% a non-medical professional. Paramedical referrals for upper limb MSDs were more frequent in case of rotator cuff syndrome diagnosis ($p<0.05$) and among younger GPs ($p<0.05$). For spinal MSDs, paramedical referrals were more frequent after a prior consultation of that GP ($p<0.05$). Medical referrals were more frequent among established GPs ($p<0.05$), in case of radiating symptoms ($p<0.01$), severity criteria ($p<0.001$), symptoms lasting for 6 weeks to 3 months ($p<0.001$), diagnosis of cervicobrachial neuralgia ($p<0.01$), orthosis prescription ($p<0.05$) or an application for social support for disabilities from the MDPH ($p<0.05$).

Discussion: Paramedical referrals were the most represented, suggesting that MSDs are predominantly managed in primary care. The referral rate was high compared with the literature, which probably reflect a memory bias when GPs are asked to report on their last consultation for MSDs. Referral patterns were particularly influenced by MSDs' characteristics.

Conclusion: The design of research on MSDs must take into account the referral pattern, to ensure the inclusion of the clinical forms relevant to the research objective.

Context: primary care research, a key element in improving the quality of primary healthcare, remains underdeveloped in France despite the multiplication of supportive measures. Community health centers (MSPs – Maisons de Santé Pluriprofessionnelles) have been identified as key environments for developing practice-based research networks due to their shared clinical information systems and commitment to quality improvement. Yet, few of them have actually engaged in it. Understanding how healthcare professionals perceive research may help explain this paradox.

Objectives: this study aimed to explore the representations and attitudes toward primary care research among professionals working in a French MSP to identify barriers and facilitators to research engagement.

Methods: we conducted a qualitative study using a grounded theory approach. Data were collected through a focus group and an individual interview with members of an interprofessional team, including a patient partner. Transcripts were coded using open, axial, and selective coding to identify emerging patterns.

Results: participants expressed a strong emotional and professional distance from traditional images of research, perceived as cold, and disconnected from their clinical reality, contrasted with their warm, experiential, and patient-centered practice. However, their collective engagement in empirically-driven, quality-improvement projects revealed underlying research-compatible competencies: evaluation skills, interprofessional collaboration, and structured care processes. Although unaware of it, teams were enacting principles akin to participatory health research and democratic engagement. Research was seen as a potential driver of internal legitimacy and external recognition, particularly when supported by tailored mentorship and grounded in everyday clinical practice.

Discussion: the study highlights how their empirical initiatives could be leveraged into research programs without disrupting clinical activity, provided that acculturation and contextualized support are offered. This overlap between quality improvement and research aligns with humanistic values and promotes equity in health systems. Recognizing experiential knowledge and fostering collaborative inquiry could catalyze a cultural shift toward inclusive and meaningful research in primary care.

Conclusion: primary care teams hold untapped potential to lead research from within their practice settings. By offering tailored support grounded in participatory approaches and interprofessional frameworks, MSPs teams can be better equipped to engage in research, thereby enhancing the quality and equity of care delivery.

ID 403- Communication between midwives and general practitioners for the post-partum medical follow-up of their patient : a qualitative study by semi-structured interviews in a CPTS' territory of the North of France.

Lucie VICENTE

Physician, Marly, France

Context: The XXX has the higher maternal mortality rate according to the 7th ENCMM. Suicide was the first cause of mortality (17%). The majority of the factors were avoidable.The lack of inter professional communication and the lack of access with medical support by the patient were the principal factors in studied cases, with the lack of description of their vulnerabilities.

Objectives: Studying on a chosen area the communication between midwifes (MW) and general practitionner (GP) in primary care in the post partum period

Methods: A qualitative study with semi-directive interwiew were done for july 2023 to may 2024. We interwiewed six MW and six GP who worked in a XXX area in XXX. A triangulated analysis was inspired from grounded theory. The transcription was verbatim.

Results: MW and GP centralized medical informations to the mother who were the mind actor of their communication. The caregivers felt competent and attentive in post partum period, but they wanted to empowered the mother for her medical follow-up. The GP met the patient while the pediatrical follow-up or the gynecologic one if it was done. MW, GP and mothers seemed to prioritize the baby medical follow-up. The post-partum follow-up was annexed to the baby's one.

Discussion: The patient is a essential partner for MW and GP communication. Her empowerement by the caregivers were granted. However, caregivers have not to divert from the post partum follow-up because of maternal risk of vulnerabilities and let her alone.

Conclusion: As an essential partner between MWs and GPs, patient could have a post partum medical record. Hospital at home program could be more proposed as soon as post partum depression is diagnosed. Caregivers have to be pay attention due to the highest maternal suicide rate in the post partum period.

ID 2291- Appropriation and selection of indicators for the MSProgress quality support tool in multi-professional health centers: a mixed-method study

Thibault MENINI

Clermont Auvergne University, Clermont-Ferrand, France

Context: The development of a quality approach within multi-professional health centres (MSPs) is key to improving the quality of care. This requires operational and accessible tools, in particular indicators that enable MSPs to self-assess over time. In 2022, a qualitative study involving semi-structured group interviews in seven MSPs, followed by a consensus method, led to the development of MSProgress, a prototype tool consisting of quantitative care indicators that can be retrieved from the Health Insurance databases. Then, in 2023, a second study made it possible to adjust and consolidate the tool before it could be deployed and evaluated on a larger scale.

Objectives: The objective of this study is to examine how the MSProgress tool is being adopted, to describe the team's indicator selection process and to understand the tool's effects on the structuring of the quality approach in MSPs.

Methods: A mixed study was conducted among 32 MSPs in the XXX region, 12 of which participated in the development of the tool and 20 of which did not. The qualitative part was based on semi-structured group interviews with professionals with analysis by triangulation using a general inductive method by thematization. The quantitative part used anonymous individual questionnaires distributed to MSPs professionals.

Results: There are multiple approaches to quality: from lack of knowledge to routine integration, the trajectories of appropriation vary according to acculturation to indicators, the uses of shared information systems, internal logic and territorial contexts. The mechanisms of decision-making are

complexe: the central role of driving duos (coordinators and medical leaders), the ambivalence of collective bodies, the differentiated weight of voices according to profession, and the importance of informal negotiations.

Discussion: MSProgress does not create cooperation but makes it visible, sometimes reinforcing it, sometimes putting it to the test. Far from being a uniform model, the appropriation of the tool appears to be a local factory of quality, situated, traversed by implicit hierarchies and ongoing negotiations.

Conclusion: The results of this study have highlighted the processes of indicator selection by teams and the organisational dynamics underlying these choices. Support for teams appears essential to reduce differences in maturity in relation to indicators.

Corresponding author: Thibault Menini, thibault.menini@uca.fr

ID 2272- Pilot study of the MSProgress quality support tool in multi-professional health centers

Thibault MENINI

Clermont Auvergne University, Clermont-Ferrand, France

Context: The development of quality procedures within multi-professional health centers (MSPs) is key to improving the quality of care. It requires operational and accessible tools, particularly indicators that enable structures to self-assess over time. In 2022, a qualitative study using semi-structured group interviews in seven MSPs, followed by a consensus method, led to the development of MSProgress, a prototype tool consisting of quantitative indicators that can be queried in the Health Insurance databases.

Objectives: The objective of this pilot study is to test the prototype tool with MSPs in order to gather collective and individual opinions on the form, understanding, and use of this tool.

Methods: A mixed study was conducted among 11 MSPs in the XXX region, six of which participated in the development of the tool and five of which did not. The sample was constituted by theoretical maximum variation. The qualitative part was based on semi-structured group interviews with professionals from these MSPs, with triangulation analysis using a general inductive method by thematization. The quantitative part used individual anonymous questionnaires distributed to professionals from these MSPs.

Results: The teams surveyed were enthusiastic about the form and use of the tool, pointing in particular to the value of having access to new data and being able to self-assess. The tool was found to be understandable, easy to use as a team, and relevant for monitoring patient care by 95%, 84%, and 88% of professionals, respectively. Comparing the results with the average for other MSPs in the region and tracking changes in indicators over time was considered interesting by 84% and 98% of them, respectively.

Discussion: One of the strengths of this work lies in the mixed method used to gather the opinions of MSP professionals at both the collective and individual levels, both from those who participated in the development of the tool and those who did not contribute to it. One of the limitations of the tool remains its restriction to the patient base of the treating physician.

Conclusion: The feedback provided enabled the prototype to be improved before its deployment and evaluation at the regional level.

Corresponding author: Thibault Menini, thibault.menini@uca.fr

ID 2252- Une salle d'apaisement pour les soignants : Un élément d'amélioration de la santé mentale des professionnels de santé en France ?

Guillaume SIMET

Cpts Pays De Gex, Sergy, France

Context: Healthcare professionals are particularly exposed to stress and burnout. They are among the professions with one of the highest suicide rates in

France. Since the COVID 19 epidemic, these professionals have also been suffering from a loss of meaning in their activities, due in part to their working conditions (understaffing, unsuitable workloads and care rhythms, physical/verbal violence, red tape, etc.).

Objectives: To raise caregivers' awareness, change their outlook and take care of their mental health, this study looked into the benefits of setting up a soothing room at the heart of the care structure, for use by caregivers. This would be a space dedicated to caregivers, using the Snoezelen universe to offer a cocoon of safety, and tools validated by neuroscience (such as mindfulness meditation, breathing exercises, micro-naps and yoga). This space would be set up by experts in co-development as well as preventive and integrative medicine.

Methods: Through a mainly qualitative study, we interviewed caregivers (10 individualized semi-directive interviews) working in a non-programmed care center (CSNP) in the Pays de Gex (01). We sought to understand their perception of work and mental health, as well as non-medicinal approaches to health. Finally, we were interested in their feelings about the implementation and feasibility of a new-generation soothing room (MERCY Space type).

Results: These interviews enabled us to gain a better understanding of the issues, false beliefs and difficulties surrounding the mental health of healthcare professionals. Indeed, there is still a great deal of prejudice, ignorance and fear surrounding the subject, not only among caregivers but also among managers of healthcare facilities.

Discussion: Thanks to this study, we were able to draw up mental health recommendations on three levels (caregivers, managers, image of mental health). One of these recommendations is to set up a MERCY Space-type soothing room in healthcare establishments.

Conclusion: In view of the obstacles (time for caregivers, budget for managers), it is essential to see these spaces as a gateway to a global, virtuous and humanistic approach to mental health for caregivers.

ID 1401- Identifying indicators for assessing the impact of nurses in general practice on multidisciplinary team functioning

Karen VAN DEN BUSSCHE, Yente BENOY, Vanessa GAUWE

Arteveldehogeschool, Ghent, Belgique

Context: Primary care faces increasing pressure due to population ageing, multimorbidity and workforce shortages. Nurses in general practice (GP) are increasingly involved in strengthening interprofessional collaboration within multidisciplinary teams. However, the indicators that best describe interprofessional collaboration in GP remain unclear.

Objectives: To identify indicators that can assess interprofessional collaboration in general practice.

Methods: Indicators were identified through a systematic review of Cochrane Library, PubMed (Medline) and Embase, complemented by expert consultation (n = 8) via co-creation workshops. Following project team review, indicators were categorised using the SEIPS work-system framework (persons, tasks, tools, organisation, internal and external environment).

Results: Sixty-seven studies met the inclusion criteria, yielding 673 indicators related to team functioning. Experts proposed an additional 42 indicators. Most literature-derived indicators fell within the SEIPS domains of organisation (n = 326) and persons (n = 246). Core themes included shared vision, clarity of roles, communication quality, leadership, team culture and structured decision-making. Expert consultation added indicators related to task expansion, mental well-being, efficiency, onboarding processes, and external collaboration. Three clusters emerged as central to interprofessional collaboration in GP: (1) shared vision on the nurse's role, (2) breadth and depth of task reallocation, and (3) frequency and structure of multidisciplinary meetings.

Discussion: The identification process revealed a substantial heterogeneity in the indicators

describing interprofessional collaboration, reflecting considerable variation in definitions and measurement approaches across studies. The limited number of GP-specific indicators highlights an evidence gap on team-level effects of nurses, necessitating a broader primary-care perspective. The SEIPS model proved the most suitable framework, capturing the complexity of multidisciplinary team functioning more comprehensively than alternative models.

Conclusion: This study provides a comprehensive, evidence-informed set of indicators for assessing interprofessional collaboration in GP. For general practices, these indicators offer practical guidance for identifying and strengthening organisational and relational factors that support effective teamwork. For research, they form an essential foundation for developing an assessment instrument to systematically evaluate interprofessional collaboration. Further research is needed to deepen understanding of collaborative processes and to inform interventions that promote sustainable, high-quality teamwork in GP.

ID 1246- Nurse professionals' educational activities in General Practice: part of a national, EU supported project in the Czech Republic

Katerina JAVORSKA, Ludmila BEZDICKOVA, Lucie SEFRHANSOVA, David HALATA

Czech Gp Society, Prague

Context: With both the population and the healthcare workforce ageing, and hospital care costs rising, strengthening primary care has become essential. Delegating selected clinical tasks to nurses is increasingly considered to reduce GP workload, but this requires structured education and competency-based training to ensure safe and effective practice.

Methods: A three-year nationwide project Support for education in primary care for general practitioners, paediatric general practitioners, and support for regional accessibility of healthcare (Project registration number: CZ.03.02.02/00/24_060/0005126), co-financed by the European Social Fund through the Employment Plus Operational Programme and the state budget of the Czech Republic, was launched by the Institute for Postgraduate Medical Education in 2025. The project includes several key activities focusing on 1. Regional GP education, 2. Competency-based education, methodology of specialty training and improvement of the assessment of education, providing education for trainers in GP, 3. Education for nurses in GP, implemented initially as a pilot program. The presented work focuses on key activity 3.

Originality: To meet GP nurses' educational needs, pilot structured courses were introduced. Because education in general practice had not previously been systematically developed, demand for the inaugural course in October 2025 was exceptionally high. Four courses ar

Lessons learned and future implication: The courses aim to establish a foundation for GP nurses' educational activities, assess current learning needs, and promote professional development. They also foster teamwork, improve care coordination, and strengthen interprofessional communication with

Discussion: To what extent is the education of GP nurses a fundamental prerequisite for strengthening their role in primary care? It equips nurses with specific skills that serve as the basis for assuming expanded responsibilities and improving patient care delivery, and deserves to be recognized.

Conclusion: Implementing nationwide GP nurses' education requires a coordinated, well-resourced effort.This EU-supported project, led by Institute for Postgraduate Health Education, represents a significant methodological advancement and provides a sustainable framework for future national and regional educational initiatives targeting nurses in general practice.

ID 1100- Interprofessional communication through prescription: perception of allied

health professionals (nurses, speech therapists, physioherapists)

Stéphane BOUXOM, Laurine BRUN, Anand SIEFFERT-REGENT

Département De Médecine Générale, Saint Etienne, France

Context: An effective healthcare system relies on structured primary care. In France, the general practitioner plays a central role in coordinating care, particularly in prescribing interventions by paramedical professionals. The initiation of care is contingent on the general practitioner writing a prescription, which often serves as the sole medium of interprofessional communication at this stage.

Objectives: This research explores the challenges and issues of interprofessional communication via medical prescription between general practitioners and health professionals in the context of ambulatory care in the french healthcare system.

Methods: This is a qualitative study using grounded theory, based on focus group interviews conducted with allied-health professionals practicing one of the following three professions in primary care : physiotherapists, speech therapists, or nurses.

Results: Interprofessional communication, which is crucial to patient care, is often reduced to medical prescription. Allied-health professionals report frequent prescribing errors, a lack of feedback from general practitioners on their assessments, and under-use of digital communication tools. They express a desire for direct exchanges.

Discussion: Communication through prescribing is limited by a nomenclature governing the acts performed by the various health professionals. Thus, a dual use of the prescription is observed : as a tool for transmitting medical information and as an administrative and financial document. This original communication is part of a constantly evolving ambulatory system. Exchanges are mainly unilateral, from the GP to the Allied-health professionals. An implicit hierarchy between them hinders dialogue and collaboration. However, allied-health professionals recognize the general practitioner as an essential care coordinator. Mutual trust is fundamental to improving communication and optimizing patient care.

Conclusion: Interprofessional communication between general practitioners and allied health professionals is complex. It reflects both the organization of the various professional groups and the constraints on the healthcare system. However, exchanges cannot be reduced to medical prescriptions. Direct, two-way communication is required to improve patient care.

ID 258- Protecting medical confidentiality in home-based end-of-life care: insights from primary care professionals

Jeanne ROLLIN

General Practice, University Of Franche-Comté, Besançon, France

Context: Medical confidentiality in home-based end-of-life care raises major ethical, relational, and organizational challenges for primary care clinicians. The home setting, the frequent presence of relatives, the involvement of multiple professionals, and the emotional intensity of this period can weaken usual confidentiality boundaries. Despite its centrality in the doctor–patient relationship, few studies explore how general practitioners and home-based palliative care teams experience and manage these dilemmas in practice.

Objectives: To explore how healthcare professionals understand, protect, and negotiate medical confidentiality in home-based end-of-life situations; to identify ethical tensions and practical barriers; and to highlight potential levers for safer, person-centred communication.

Methods: A qualitative study using grounded theory methodology was conducted. Semi-structured interviews were carried out with general practitioners, home-hospitalization physicians, and palliative care professionals involved in home-based end-of-life care. Data were analysed through open, axial, and selective coding with constant comparison until theoretical saturation. A double-coding process strengthened internal validity. All data were fully anonymized.

Results: Eight categories emerged. (1) Identifying legitimate interlocutors: uncertainty often exists about who may receive information. (2) Protecting vulnerable patients: "reverse confidentiality," where relatives request that information be withheld, was frequently reported. (3) Coordinating without breaches: unclear definitions of the "care team" hinder secure information-sharing. (4) Choosing communication tools: paper is seen as simple but exposed; digital tools offer security but remain heterogeneous and sometimes impractical. (5) Supporting caregivers: their involvement is essential yet may destabilize confidentiality. (6) Managing emergencies: time pressure can lead to unintentional breaches. (7) Balancing family expectations: clinicians negotiate between legal obligations and maintaining relational alliance. (8) Maintaining trust: confidentiality is viewed as key to safe end-of-life care.

Discussion: Confidentiality at home in end-of-life care is a dynamic negotiation shaped by relational and organizational factors. The findings underline the need for clearer shared rules, secure tools, and structured ethical reflection within primary care teams.

Conclusion: Strengthening confidentiality in home-based end-of-life care requires clarifying team boundaries, improving shared communication tools, supporting caregivers, and reinforcing ethical training. These levers help preserve trust—an essential thread in the final moments of care.

Medical education

ID 1975- Observational study of a primary care teaching program in undergraduate medical education

Constance MARTIN, Cyril BEGUE, Matthieu PEUROIS

Author, Angers, France

Context: In XXX, most of undergraduate medical education takes place in hospitals and it has been noted that students have little knowledge of primary care and general medicine. As a result, an optional "Primary Care" course was introduced in 2023–2024 for medical students.

Objectives: To describe and evaluate an optional primary care teaching program implemented for second-cycle medical students.

Methods: This was a mixed-methods observational study combining qualitative and quantitative approaches, conducted among students who participated during the 2024–2025 academic year. Data collection was carried out through direct, in-person, non-participant observation using an observation grid equivalent to a structured field note logbook. The evaluation of the optional course was conducted using a questionnaire distributed to participants.

Results: The program consisted of 34 hours of teaching sessions, 8 hours of clinical placement and 14 hours of independent work covering four main themes: chronic diseases, women's health, child and adolescent health, and occupational health. Teaching methods were diverse and primarily based on clinical cases and small-group work, supplemented by role-playing activities and multimedia resources. Student attention appeared to be greater when teaching methods were varied, based on real clinical situations, and when group work was limited to short durations. Students gave the course an average rating of 7.67/10 and largely recommended it. The most appreciated teaching methods were discussions based on clinical situations encountered by teachers in general practice, small-group work on clinical cases, and the use of alternative materials (videos, graphic novels, testimonials).

Discussion: Primary care remains insufficiently visible to second-cycle medical students despite their interest. Highlighting this specialty early in medical education could lead to a better understanding of the role and place of general practitioners in the healthcare system.

Conclusion: Primary care teaching in the second cycle of medical studies should be further developed using innovative teaching methods. Keywords: primary care, professionalism, medical students

ID 1941- Descriptive study of debriefing following simulated consultation for general practice residents

Alexandra LEMAISTRE

General Pratice Departement Of Rouen, Rouen, France

Context: In X, communication skills training for general practice residents begins with a simulated consultation followed by a debriefing. Debriefing is a well-established educational tool that aims to engage learners and support skills acquisition. Debriefings need to be refined in order to fulfill these goals.

Objectives: The primary objective of this study was to explore how debriefing sessions are conducted. The secondary objective was to explore structural components of debriefing associated with hight facilitation.

Methods: We performed a quantitative analysis of transcripts from 48 simulated consultation debriefing sessions. Several criteria were assessed: speaking time, whether or not each phase of a four-phases debriefing structure were present (reaction, description, analysis, synthesis), the number of educational points addressed, the number of learning recommandation made to the learner, and the level of facilitation, assessed using a Likert scale.

Results: Facilitation was rated as hight in 31% of debriefing sessions. The learner's mean speaking time was 4 minutes and 29 seconds, representing 29% of the total debriefing duration. Learners addressed an average of 3.8 educational points, compared with 6 points addressed by teachers. Learners formulated an average of 0.8 learning recommandations, versus 2.5 by teachers. When facilitation was hight, learner speaking time was higher ($p < 0.001$) and communication students addressed more educational points ($p=0.006$) .

Discussion: Debriefing can be more or less reflective in nature. Hight facilitation reflects a reflective debriefing, in which the learner is placed at the center of the learning process and the teacher acts as a catalyst for reflection. Reflective debriefings are associated with better knowledge retention, increased motivation, and enhanced self-assessment skills. However, to allow novice learners to focus on core concepts, a more explicit approche, characterized by a lower facilitation, may be used.

Conclusion: Reflective debriefing, characterized by hight facilitation and associated with greater learner speaking time and learner-generated educational points, appears to promote durable learning. Further research could explore the role of reflexivity in interprofessional debriefing within primary care settings.

Corresponding author: Alexandra Lemaistre, alexandra.lemaistre5@univ-rouen.fr

ID 1710- Personalised formative Objective Structured Clinical Examinations including individual debriefing: a new tool for undergraduate students experiencing difficulties in their general practice placement

Loïc DRUILHE, Jules VILLEMANT, Agathe EDELINE, Clarisse DIBAO-DINA, Cécile RENOUX

Médecine Générale, Tours, France

Context: The general practice placement during the second cycle of medical education allows students to be supervised by university-accredited general practitioner tutors. This setting promotes observation and guided practice of consultations, offering a privileged opportunity to identify potential student difficulties, whether in communication, doctor–patient relationship, physical examination, or clinical reasoning. However, for students identified as having difficulties in one or more of these skills, the duration of the placement, which is mostly 3 to 6 weeks in region XXX, does not allow for optimal progress.

Objectives: The primary objective of this study was to explore the experiences of students who participated in a formative Objective Structured Clinical Examination (OSCE) that included individual debriefing following a general practice placement during which difficulties were observed.

Methods: This was a qualitative study using an interpretative phenomenological approach,

conducted among 4th- and 5th-year medical students. Students experiencing difficulties were identified using an internship assessment form based on the skills listed in the Learning Progress Booklet. The selected students took part in a formative and personalized OSCE session followed by an individual debriefing. Two months later, semi-structured interviews were conducted with volunteer participants to explore their perceptions.

Results: Seventeen of the twenty-four students selected participated in interviews between March 2023 and March 2024. They appreciated the clarity of instructions, the supportive environment and the individualized feedback, which helped build their confidence, understand theirs difficulties and support their progress. Analysis of interviews led to the identification of four distinct student profiles: the emotive, overwhelmed by stress and self-doubt; the perfectionist, driven by a pursuit of excellence; the technician, focused on methodological rigor; and the uninvolved, displaying limited engagement.

Discussion: The formative OSCE, combined with individual debriefing, proved to be an interesting tool to support students based on their specific needs. To our knowledge, this study is the first to describe profiles of students experiencing difficulties in their second-cycle general medicine placement.

Conclusion: A larger-scale evaluation is needed to confirm its long-term benefits on clinical skills and its feasibility.

Corresponding author: Loïc Druilhe, druilheloic@orange.fr

ID 933- Ecology of care for patients encountered in the progressive case studies of the French National Ranking Examination between 2016-2022.

Kim BONELLO, Hugo FIGONI, Elise ARCHER, Sohela MOUSSAOUI

Sorbonne Université, Paris, France

Context: The ecology of care, theorized by White (1961), conceptualizes the population's use of health services and highlights the pivotal role of primary care (PC) and its main providers, general practitioners (GPs). The content of high-stakes examinations guides students' learning and may convey a specific vision of the health system. In France, medical students take a national ranking examination in their 6th year, which determines their choice of specialty. No study had described the ecology of care for patients encountered in this examination.

Objectives: To describe the ecology of care for patients encountered in the French National Ranking Examination (ECNi) between 2016 and 2022.

Methods: A quantitative descriptive study was conducted on all questions from the progressive case studies of the ECNi between 2016 and 2022. The levels of care (primary/secondary/tertiary) and the care settings (ambulatory/hospital) were assessed by two researchers blinded to the other's findings, with recourse to a third party if there was disagreement. To model the ecology of care for patients present in the ECNi case studies, White's methodology was used and adapted to the data. A monthly rate of healthcare utilization per 1000 patients is presented.

Results: In total, 1,858 questions from 126 progressive case studies were examined. The ecology of care shows that for 1000 patients who sought care at least once during a month (consultation or hospitalization), 355 consulted a GP at least once, 566 consulted another specialist, and 152 were admitted to a tertiary care hospital.

Discussion: This is the first study to evaluate the ecology of care in a high-stakes examination. The levels/settings were not always explicitly stated; however, a double reading helped to limit this bias.

Conclusion: The ECNi presented an unbalanced ecology of care, overrepresenting secondary and tertiary utilization compared to general practice, relative to the reality of the French health system. This discrepancy could bias students' clinical reasoning and negatively influence their perception of general practice, as well as their career orientation.

Corresponding author: Kim Bonello, kim.bonello@sorbonne-universite.fr

ID 931- The Place of Primary Care in the French National Ranking Examinations (ECNi) from 2016–2022

Hugo FIGONI, Kim BONELLO, Sohela MOUSSAOUI, Elise ARCHER

Sorbonne Université, Paris, France

Context: Primary care (PC) and its main actors, general practitioners, are facing a crisis of attractiveness. The choice of general practice is influenced by experiences gained throughout medical training. In France, between 2016 and 2022, all medical students took a National Ranking Examination (ECNi) in their 6th year, which determined their choice of specialty and residency location. Based on the principle that assessments can influence learning and potentially career choices ('assessment drives learning'), we aimed to describe the representation of PC in the ECNi.

Objectives: To quantify the proportion of progressive case study questions in the ECNi (2016–2022) that place the student in a Primary Care context and to describe the characteristics of these questions.

Methods: All questions from the progressive case studies of the ECNi between 2016 and 2022 were studied. The healthcare level (primary, secondary, or tertiary) and the characteristics of the questions (fundamental, clinical, skills assessed, and complexity according to the revised Bloom's taxonomy) were assessed by two researchers blinded to the other's findings, with recourse to a third party in case of disagreement.

Results: Out of 1,858 questions analyzed, 407 (21.9%) were related to a Primary Care context. This proportion varied from 7.8% in 2017 to 34.3% in 2020. The competencies most frequently assessed in this context were clinical examination (21.1%), management strategy (19.9%), and medical interview (19.7%).

Discussion: This is the first study evaluating the place of PC in a high-stakes ranking examination. The contexts (setting/specialty) were not always explicit; however, a double reading helped to limit this bias.

Conclusion: PC was underrepresented in the ECNi compared to its importance in the health system. This imbalance could contribute to a poor understanding of the role and missions of general practice by limiting students' exposure to its specificities via the assessment. It thus appears necessary to better represent PC in medical education assessment methods. The introduction of Objective Structured Clinical Examinations (OSCEs) in the new ranking examinations (EDN/ECOS) since 2023 represents an opportunity to better highlight PC-specific competencies.

Corresponding author: Hugo Figoni, hugo.figoni@sorbonne-universite.fr

ID 371- Evolution of the attractiveness of the general practice specialty in France from 2004 to 2024

Eloise RALITE [(1)] , Claire DELY [(2)], Yoann MALLET [(2)], Anthony CHAPRON [(1)], Jean-Sébastien ALLAIN [(2)]

(1) Université Rennes 1, Rennes, France
(2) Ghbs, Lorient, France

Context: In France, the specialty "general practice" was created in 2004. It is accessible after a national competitive examination taken by sixth-year medical students. Students choose their specialty according to their ranking.

Objectives: To evaluate the attractiveness of the "general practice" specialty in France from 2004 to 2024.

Methods: This was a retrospective descriptive study including all students assigned after the national ranking exam at the end of the sixth year (Legifrance database). The data collected included: year of the exam, gender, rank, specialty, and residency city. Unfilled positions were also recorded. An attractiveness indicator "I" was calculated for general practice, then for each training city. The indicator ranges from 0 (high attractiveness) to 1 (low attractiveness).

Results: Between 2004 and 2024, 141,477 students were assigned to residency positions across 28 cities, of whom 61,504 (43.4%) entered general practice. Women account for 64% of the students

ranked in general practice. Over 20 years, 91.4% of the positions opened in general practice were filled. The percentage of unfilled general practice positions decreased from 33.1% in 2004 to 1.5% in 2024. Over the study period, general practice became more attractive in France: I = 0.91 in 2004; I = 0.78 in 2024 ($p < 0.05$). The three most attractive cities for general practice were Rennes (I = 0.68), Grenoble (I = 0.68), and Nantes (I = 0.72), while the least attractive were Reims (I = 0.87), Limoges (I = 0.89), and Amiens (I = 0.89). Over the period 2010–2024, the attractiveness of general practice was higher among women than among men (0.85 in 2010 to 0.77 in 2024 vs. 0.89 in 2010 to 0.80 in 2024, $p < 0.05$).

Discussion: The "I" indicator accounts for the variability in the number of positions offered over time, allowing comparisons across years and cities.

Conclusion: The attractiveness of general practice has improved since the creation of its specialty in 2004. Differences in attractiveness persist between training cities.

ID 205- Factors influencing the choice of « General Practice » as a specialty among French medical students in their clinical studies in the Île-de-France region

Camille ANDRAULT, Nicolas DUBREUIL

Dmg Université Paris Cité, Paris, France

Context: Despite increases in physician numbers in France, the aging of both the population and the medical workforce has expanded underserved areas. General practice, the primary care specialty, faces declining student interest, particularly in the Île-de-France region. Understanding the determinants of specialty choice is essential to address this crisis.

Objectives: To identify factors influencing specialty selection among medical students using Beaulieu's validated French-language questionnaire, adapted to the French medical education context.

Methods: The adapted questionnaire was distributed to three cohorts of medical students across three Parisian universities. Responses from 792 students (19.82% intending to pursue general practice) were analyzed using exploratory factor analysis and logistic regression.

Results: Factor analysis yielded constructs that diverged from the original validation, with certain questionnaire items requiring individual treatment. The logistic regression model explained over 60% of variance in specialty choice. Intention to pursue general practice was significantly associated with completion of ambulatory general medicine clerkships during clinical training, societal commitment, and preference for reduced training requirements. Conversely, perceived limited scope of practice, hospital career orientation, and completion of clerkships in the desired future specialty were negatively associated with choosing general practice.

Discussion: These findings highlight the critical role of ambulatory clerkship exposure and suggest that inadequate representation of general practice during medical training may contribute to declining interest in the field.

Conclusion: General practice selection is primarily driven by desires for professional autonomy and flexibility, yet the specialty remains underrepresented in students' clinical experiences.

ID 2202- Understanding autonomous learning in general practice after initial training: a qualitative study

Abdelkader LAHMAR, Ilham MOUZOUNA

University Of Strasbourg, Strasbourg, France

Context: After completion of initial training, general practitioners must continuously update their competencies to respond to evolving clinical and organisational demands. Lifelong learning is

central to professional responsibility, quality of care, and patient safety in primary care. However, how general practitioners engage in autonomous learning in everyday practice remains insufficiently explored.

Objectives: The primary objective of this study was to explore how general practitioners learn autonomously after their initial training. We aimed to identify learning strategies, sources, facilitating and limiting factors, and the role of reflexivity in self-directed learning within primary care.

Methods: We conducted a qualitative, non-interventional study between April and September 2024 in a primary care setting. Using iterative theoretically reasoned sampling, nine general practitioners were recruited. Data were collected through semi-structured interviews focusing on learning experiences, learning processes, and situations triggering learning in routine practice. Data were analysed using a qualitative approach inspired by grounded theory, with iterative coding and constant comparison to identify emerging themes.

Results: General practitioners reported diverse learning strategies combining formal, informal, and experiential learning. Sources included continuing professional development activities, medical literature, online resources, digital tools, peer groups, and interactions with specialists, students, other healthcare professionals, and patients. Learning was often triggered by clinical situations, uncertainties, or perceived limits. Reflexivity emerged as a central process, enabling physicians to analyse their actions, recognise learning needs, and adapt their practices. Facilitating factors included intrinsic motivation, professional responsibility, access to resources, peer support, and opportunities for interaction. Barriers included time constraints, organisational workload, administrative burden, motivational fluctuations, and difficulties accessing or evaluating information. Participants described ambivalent feelings, combining satisfaction and stimulation with frustration, fatigue, and concerns about keeping up with evolving medical knowledge.

Discussion: Autonomous learning among general practitioners appears as a complex, dynamic, and largely self-regulated process embedded in daily clinical practice. Informal learning, social interactions, and reflexivity play a key role, alongside institutional training.

Conclusion: General practitioners rely on diverse, self-directed learning strategies after initial training, with reflexivity and social interactions playing a central role. Supporting autonomous learning through accessible resources, peer exchanges, and recognition of informal learning may strengthen professional development and quality of care in primary care.

Corresponding author: Ilham Mouzouna, ilham.mouzouna@etu.unistra.fr

ID 1592- Periodic Certification in General Practice: International Evidence and Lessons for Practice

Hugo HUCHELOUP

Université De Lille, Lille, France

Context: Globally, periodic certification systems are being implemented to ensure that general practitioners (GPs) maintain up-to-date knowledge, provide high-quality care, and adapt to evolving patient needs. France is implementing its model without a consolidated synthesis of international evidence. A rigorous literature review is necessary to inform policy decisions and support the profession.

Objectives: To synthesise international evidence on the impact of periodic certification for GP, focusing on four domains defined by the French framework: (1) updating knowledge and skills, (2) improvement of clinical practice, (3) doctor–patient relationship, and (4) physicians' personal health.

Methods: A systematic review was conducted following PRISMA 2020 guidelines. Searches were performed in PubMed using a predefined strategy combining terms related to general practice, certification/recertification, assessment, professional competence, and continuing professional development. Inclusion criteria were: (i) studies evaluating certification, recertification, maintenance of certification or multisource feedback; (ii) physicians in primary care; (iii) quantitative, qualitative, or mixed-methods designs; (iv) English or French. Exclusion criteria were: lack of outcome data, non-physician populations, opinion

papers. Screening, eligibility assessment, and data extraction were performed independently by one reviewer. Studies were categorised according to the four blocks, and findings were synthesised narratively due to heterogeneity.

Results: Fifty-eight studies met the inclusion criteria. Periodic certification enhances knowledge acquisition and guideline adherence, particularly when interactive or workplace-based educational methods are employed. Maintenance of certification examination scores was correlated with improved quality-of-care indicators, notably vaccination rates, chronic disease monitoring, and reduced avoidable hospitalizations. Peer-review and multisource feedback enhanced reflective practice and communication skills, contributing to greater patient satisfaction. Several studies suggested potential protective effects against burnout, associated with increased sense of competence and professional mastery. Barriers included administrative burden, limited time, and low perceived relevance for some physicians.

Discussion: International evidence consistently indicates that certification processes—when educational, supportive and context-adapted—benefit both practitioners and patients. Resistance arises when systems are perceived as bureaucratic or disconnected from practice realities.

Conclusion: Periodic certification can support quality improvement in general practice. Aligning certification with flexible learning formats, peer involvement, and adequate organisational support may enhance acceptability and impact. Future research should evaluate cost-effectiveness and long-term outcomes in the French context.

Corresponding author: Hugo Hucheloup, hugo.hucheloup@univ-lille.fr

ID 1642- Facilitators' Experiences in Reflective Practice Groups for GP Trainees: A Qualitative Study

Jérôme FONSECA, Longépé LONGÉPÉ, Jeanlin VIALA, Marie BARAIS

University Department Of General Practice (xxx), Brest, France

Context: Since general practice has been recognised as a medical specialty, postgraduate training has shifted towards learner-centred, experiential and reflective approaches. Reflective Practice Groups are integrated into general practice training to support critical thinking, peer learning, and professional identity development. While trainees' experiences are well documented, facilitators' perspectives remain underexplored despite their key role in guiding reflection and group dynamics

Objectives: To explore facilitators' lived experiences and perceptions of their role in faculty-led reflective practice groups for general practice trainees, and to identify perceived benefits, challenges, and areas for improvement.

Methods: A qualitative study with an interpretative phenomenological approach was conducted in a university department of general practice (XXX). Fifteen experienced facilitators participated in semi-structured interviews conducted between March and July XXXX, face-to-face or via videoconference. Interviews were recorded, transcribed verbatim, anonymised, and analysed using inductive thematic analysis with independent double coding. Data collection continued until sufficient thematic depth was achieved. Ethical approval was obtained according to national regulations (XXX).

Results: Facilitators reported a progressive learning of their role through peer observation and experiential learning. Facilitating these groups was perceived as professionally rewarding, enhancing pedagogical skills, reflexivity, and a sense of belonging to an educational community. However, participants also described constraints related to workload, time pressure, and emotional fatigue. Group size and uneven trainee engagement were identified as barriers to effective facilitation. Co-facilitation was consistently valued for providing complementary perspectives and mutual support. Four main themes emerged: training and preparation, organisation and workload, group dynamics and trainee engagement, and facilitators' well-being and motivation.

Discussion: This study highlights the ambivalence of the facilitator's role, balancing guidance with restraint to preserve trainees' reflexivity. The lack of formal training, particularly for online facilitation, emerged as a key challenge. Beyond trainee learning, reflective practice groups also appear to support facilitators' own professional development and collective learning.

Conclusion: Facilitators perceive reflective practice groups as meaningful but demanding educational settings. Addressing workload, optimising group size, and strengthening facilitator training may enhance their sustainability and pedagogical impact. These findings are transferable to similar reflective learning contexts in general practice training.

Corresponding author: Jérôme Fonseca, jeromefonseca@hotmail.com

ID 1597- Impact of a general practice internship on medical students' perceptions of the specialty: a before–after study

Maxime ROZES, Théo DUGUET

Sorbonne Université, Paris, France

Context: General practice (GP) will be the chosen specialty for a substantial proportion of medical students after the sixth-year board exam. GP internship, which became universal in XXXX in 2009, may influence both the perception and attractiveness of GP. Few studies have examined the impact of this mandatory internship, and none have done so at XXXXX.

Objectives: To assess changes in beliefs about GP and in the intention to choose GP as a specialty among medical students at XXXXX after completion of a GP internship before board exam.

Methods: A prospective before–after questionnaire study between October 2021 and June 2022 third-year students' class was conducted. A questionnaire was developed from 22 preconceived ideas about GP collected during workshops with previous classes. To assess changes in students' agreement with these statements, responses (5-point Likert scale) before and after the internship were compared using paired Student's t-tests with a 5% alpha risk.

Results: A total of 137 students (41% of the class) completed both questionnaires. Twelve items changed significantly over time. Perceived complexity of GP increased by +0.36 [95% CI 0.20 to 0.51], p<0.001, while the perception of professional isolation decreased by −0.41 [−0.58 to −0.23], p<0.001. Recognition of GP as a specialty improved (+0.22 [0.07 to 0.38], p<0.05), as did the intention to choose it (+0.21 [0.05 to 0.37], p<0.05). Students reported greater perceived workload (+0.30 [0.14 to 0.47], p<0.001) and better remuneration (+0.40 [0.24 to 0.57], p<0.001). Three items decreased, notably the idea that "choosing GP means giving up another specialty" (−0.18 [−0.33 to −0.03], p<0.05) and that GP is necessarily practiced in private practice (−0.24 [−0.42 to −0.06], p<0.001).

Discussion: The process of identifying preconceived ideas directly with medical students yielded a list closely aligned with their perceptions. The prospective before–after design and paired analysis strengthen the robustness of the findings. However, only 41% of the target class could be included.

Conclusion: This study suggests that a GP internship helps deconstruct certain misconceptions and enhances the attractiveness of the specialty, thereby supporting the continuation of such placements for all medical students.

Corresponding author: Maxime Rozes, maxime.rozes@sorbonne-universite.fr

ID 1207- Design and Implementation of an Innovative Blended Certificate Program for NCD Care in Lebanon

Mona OSMAN

American University Of Beirut, Beirut, Liban

Context: Non-communicable diseases (NCDs) are a leading public health challenge globally and account for more than 85% of adult mortality in Lebanon, a lower–middle-income country facing significant health system strain. Strengthening the capacity of primary health care (PHC) providers, particularly general practitioners and family physicians, is

essential to improving prevention and management of NCDs. This session presents the development and early implementation of a national Certificate in NCD Care tailored for the PHC context.

Methods: A needs assessment was conducted among general practitioners and family physicians working across Ministry of Public Health–affiliated PHC centers. The assessment examined their knowledge, attitudes, and practices related to NCD prevention and management, along with specific learning needs.

Originality: This is the first structured, nationally aligned NCD training program for PHC providers in Lebanon, integrating online modules, interactive case-based sessions, and supervised on-the-job clinical training. The program is designed to be scalable, adaptable

Lessons learned and future implication: The Certificate in NCD Care spans six months and employs a blended format that combines self-paced e-learning, in-person case discussions, and workplace-based learning. Implementation has begun with a goal of training at least one provider in each of the

Discussion: The development process revealed several key factors necessary for successful implementation, including alignment with national guidelines, availability of digital infrastructure, and the need for protected learning time within busy PHC settings. Challenges included variable digital literacy and competing clinical responsibilities, while facilitators included strong engagement from PHC leadership and the blended design that accommodates diverse learning needs.

Conclusion: The introduction of a national Certificate in NCD Care offers an innovative and practical approach to strengthening PHC providers' competencies in NCD management in Lebanon. As implementation expands, this model has the potential to enhance quality of care, improve patient outcomes, and serve as a scalable training strategy for similar settings.

ID 878- General Practice Residents' Perceptions of Practice Exchange Groups: A Qualitative Study

Paul AUJOULAT, Jeanlin VIALA

Ubo, Brest, France

Context: The training of general practice residents is evolving from a vertical model based on knowledge transmission to a peer-based co-construction approach. Practice Exchange Groups (GEP) fit within this dynamic by promoting the sharing of experiences and collective reflection on situations encountered during clinical rotations. Although their development responds to current educational priorities, little is known about how residents perceive them. Exploring their views is essential to adapt these tools to the needs of primary care training.

Objectives: To describe general practice residents' perceptions of GEP, identifying facilitating factors, barriers, and avenues for improvement.

Methods: A descriptive qualitative study was conducted among residents who had participated in GEP. Ten semi-structured interviews and six focus groups were carried out. Verbatim transcripts underwent inductive thematic analysis following Braun and Clarke's methodology, with independent double coding and triangulation.

Results: Residents identified several facilitators: the videoconference format, an appropriate session frequency (once per month), and a workload considered reasonable. A supportive atmosphere and the participatory stance of the facilitators were also perceived as strengths. GEP were appreciated for their practical relevance and for enabling the sharing of clinical experiences. However, residents also reported barriers: rapid implementation during the health crisis, poorly defined educational objectives, repetitive themes, variability in teacher engagement, and occasional confusion about role distribution. The bibliographic work was considered superficial, and GEP did not seem to directly encourage peer-led groups.

Discussion: Residents view GEP as useful for developing reflective skills, provided that their structure and objectives are well defined. The discrepancies in facilitation practices and lack of

clarity regarding pedagogical aims appear to limit their perceived impact. Although strengthened by methodological triangulation, the findings stem from a single training region and a post-pandemic context, which may influence transferability.

Conclusion: GEP are a relevant tool to support reflective practice in general practice training. Enhancing interprofessional coordination, clarifying objectives, and standardizing facilitation methods could improve their effectiveness and sustainability.

ID 463- The Adopteunethese.fr project, Designing a digital matching platform between general practice interns and thesis supervisors

Stéphane BOUXOM, Dragos-Paul HAGIU, Bilal KALAY, Aurélien FALCON

Département De Médecine Générale, Saint Etienne, France

Context: Thesis projects are a requirement for completing residency programs in France, serving a dual purpose : educational validation and research promotion. However, several challenges exist, such as the difficulty of engaging interns in research projects and the complexity they face in finding suitable thesis supervisors. These issues are exacerbated by recent reforms in the third cycle of medical education.

Objectives: The aim of this work is to create a platform that facilitates the connection between general practice interns and supervisors, optimizing research and the management of thesis projects in general practice.

Methods: The development followed the SAM (Successive Approximation Model) with three phases: preparation, iterative design, and iterative development. A needs assessment was conducted via a questionnaire distributed to general medicine academics. A first version of the platform was built and improved based on user feedback. Evaluation was conducted using the System Usability Scale (SUS) and focus groups.

Results: The platform, accessible at adopteunethese.fr, easily facilitates the formation of pairs aligned with users' interests and competencies. As of June 2024, it has 432 members, 44 thesis projects, and 9 successful pairings. The SUS score was 80, indicating good usability. Focus groups highlighted the need for improvements such as more precise search filters, rephrasing certain terms, and a more active promotion to increase platform usage.

Discussion: Adopteunethese.fr is a free online tool developed to effectively address the current challenges of the fourth year in French general practice. Although improvements are necessary, it is considered useful and user-friendly.

Conclusion: By incorporating suggestions and expanding its application, the platform could become a key tool for the medical academic community.

ID 1701- Characteristics of Audience Participation During the 2022 General Practioner Annual Conference

Laura PARIENTE, Florence PASQUIER

Sorbonne Université, Paris, France

Context: Gender inequalities in professional settings remain significant in XXXX. According to the High Council for Equality, women often adopt avoidance strategies in their verbal participation to protect themselves from sexist behaviours. In medicine, although women now represent the majority of general practitioners (52.5%), their presence in academic positions remains low (31.0% in 2021). International literature suggests that women intervene less frequently during scientific conferences.

Objectives: Describe the characteristics of audience participation during the 2022 December conference of the XXXX College of General Practice Teachers (XXXX), and explore the influence of

several factors—including gender, age, and room size—on the likelihood of speaking up.

Methods: We conducted a prospective, descriptive, comparative (chi2, student), analytic (logistic regression using R++) observational study across 50 sessions. Two anonymous surveys were completed by 17 investigators : one describing session characteristics (room occupancy and audience composition), and one describing each intervention (perceived age and gender, duration, and content). Current ethical laws have been respected.

Results: Among the 2,880 participants (69.9% women), 753 audience interventions were analysed. Women accounted for 55.1% of speakers but only 41.7% of those taking the floor—representing only one out of six women present at the conference. The cumulative speaking time was significantly longer for men (5h23) than for women (3h03), corresponding to a 176% male overrepresentation ($p < 0.001$). Analyses showed that women were more likely to intervene in medium-sized rooms (45.2%, vs. 33.8% in large rooms and 37.0% in small rooms). Speaking up was also more likely when the presenter was a woman (OR=1.49, 95%CI[1.11–2.01]).

Discussion: Strengths are : the first study during a conference in family medicine in XXXX, and a majority of sessions covered. Potential inter-investigator variability is a limitation of data collection. Despite near gender parity among speakers, women participated less frequently in audience discussions. Room size and the gender of the presenter influenced women's participation. Results were coherent with 3 other international studies in medical conferences.

Conclusion: Gender influences the likelihood of speaking up during scientific conferences among general practitioners. A qualitative study is now underway to explore the mechanisms underlying these differences. The aim is emerging tracks to a better gender equity.

Corresponding author: Florence Pasquier, dr.fpasquier@gmail.com

ID 1643- The Influence of Role Modelling by General Practice Supervisors on Residents' Learning: A Qualitative Study

Jérôme FONSECA, Brieux LONGÉPÉ, Marie BARAIS

University Department Of General Practice (xxx), Brest, France

Context: Outpatient training is a cornerstone of general practice residency and plays a key role in residents' professional identity formation. During this immersion in ambulatory care, general practice supervisors act as role models, shaping clinical reasoning, professional values, and attitudes through daily practice. While supervisors' educational role is recognised, the mechanisms through which role modelling influences residents' learning remain insufficiently explored.

Objectives: To explore general practice residents' perceptions of their supervisors' influence during the first ambulatory internship, focusing on role modelling and its impact on learning and professional identity formation.

Methods: A qualitative study using a phenomeno-pragmatic approach inspired by grounded theory was conducted in a university department of general practice (XXX). Ten residents were purposively selected to ensure diversity of profiles. Semi-structured interviews were conducted between November XXXX and January XXXX, recorded, transcribed verbatim, anonymised, and analysed using inductive thematic analysis with independent double coding. Data collection continued until sufficient thematic depth was achieved

Results: Supervisors were described as influential role models across four domains: clinical skills and knowledge, doctor–patient relationship, construction of professional practice, and career orientation. Role modelling occurred mainly through observation of supervisors' clinical reasoning, relational attitudes, ethical positioning, and organisational choices. The quality of the supervisor–resident relationship—trust, support, and adaptability—was identified as a key condition for effective role modelling. Educational practices combining supervision, progressive autonomy, and reflective feedback enhanced learning and

engagement, whereas hierarchical or distant relationships limited identification processes.

Discussion: These findings highlight role modelling as a central pedagogical mechanism in outpatient general practice training, embedded in everyday clinical interactions. Supervisors influence residents not only through explicit teaching but also through implicit behaviours and professional postures, underscoring the importance of reflexivity regarding this modelling role.

Conclusion: General practice supervisors play a decisive role in residents' professional identity formation through role modelling. Strengthening pedagogical training, particularly around awareness of implicit modelling, may enhance the educational value of outpatient training. These findings are transferable to similar primary care training settings internationally.

ID 1338- Cinemeducation: exploring expert expectations for a film-based educational tool in general practice using a consensus method

Alexandre-Giacomo MARCEL, Meïdi KOUYA

Sorbonne Université, Paris, France

Context: Through its emotional impact, its capacity to foster identification, and its integration of humanities-based analytical approaches, film-based medical education (cinemeducation) has demonstrated its usefulness in promoting empathy, reflexivity, and professionalism among medical students. In this context, the Cine-Kit was developed as a ready-to-use pedagogical tool for general practice teachers, offering a selection of film and series excerpts with complementary resources to support workshops on delivering bad news.

Objectives: This study aimed to explore the perspectives of medical educators and cinemeducation experts, in order to identify key expectations regarding such a tool, priority areas for improvement, and essential elements to preserve for its effective implementation in real teaching settings.

Methods: A Nominal Group Technique (NGT) was used as a structured consensus method. Two separate panels were constituted: general practice teachers and experts in cinemeducation. Each session followed the standard NGT steps (silent idea generation, round-robin sharing, clarification, and anonymous ranking). Forty-two proposals were formulated, clarified, and grouped into thematic categories for analysis.

Results: Participants emphasized the need for a clear and structured pedagogical framework, including session flow, objectives, and assessment strategies. Analytical tools (cinematographic or grounded in social sciences) and diversity in the excerpts (in content, tone, and form) were considered essential but requiring further development. Access to the tool through an ergonomic and secure online platform was strongly supported. Some features were consensually valued, such as realistic, non-caricatured situations and excerpts that are meaningful on their own. General practice teachers highlighted the importance of a ready-to-use format, while cinemeducation experts insisted on the need for interdisciplinary analytical tools.

Discussion: Although perceived as already operational, the tool requires further refinement. It shares similarities with existing initiatives, yet its modular extract-based structure sets it apart. The NGT enabled the identification of shared priorities, but the exploratory nature of the method invites cautious interpretation.

Conclusion: The Cine-Kit appears to be an innovative pedagogical tool for teaching bad news delivery. Future implementation and evaluation across diverse teaching settings will help assess its adaptability, broaden its scope to other competencies and disciplines, and guide further research.

Corresponding author: Alexandre-Giacomo Marcel, alex.g.marcel@gmail.com

ID 493- Evaluation of pedagogical and organisational quality of general pratice

residency training sites at the University of XXX

François QUERSIN, Ugo BON

University Of Lille, Lille, France

Context: Workplace-based learning through clinical rotations is central to general practice (GP) training in XXX. The pedagogical and organisational quality of training sites directly influences competency acquisition, wellbeing, and professional identity development among GP residents. Although national guidelines define expectations for both hospital and ambulatory clinical training sites, substantial heterogeneity persists. At the University of XXX, no centralised system existed to assess whether all training sites met these standards.

Objectives: The primary objective was to evaluate the organisational and pedagogical quality of all clinical training sites available to GP residents at the University of XXX. A secondary objective was to explore whether the residents' ECN ranking (which determines access to preferred placements) was associated with perceived training quality.

Methods: A cross-sectional descriptive and analytical study was conducted using an online questionnaire (LimeSurvey) distributed to all GP residents completing a rotation between November 2024 and May 2025. The questionnaire incorporated criteria from national charters for hospital and ambulatory training sites. Descriptive statistics were performed, followed by a Kruskal–Wallis test and Dunn post-hoc comparisons for pedagogical quality scores, Fisher's exact test for recommendation rates, and Spearman correlation and logistic regression for the secondary objective.

Results: Among 504 eligible residents, 160 complete responses were analysed. Overall, training sites were positively perceived and frequently recommended (>85% in most settings). However, students consistently reported insufficient supervision for academic written work (portfolio, reflective assignments) and a lack of structured mid-rotation feedback. Working-hour regulations were frequently exceeded in hospital placements, particularly in medicine and emergency departments. Hospital gynaecology placements received significantly lower pedagogical quality scores than other training sites ($p<0.05$). A weak negative correlation was observed between ECN ranking and perceived quality ($\rho = -0.130$, $p=0.05$), with a stronger association in gynaecology training sites ($\rho = -0.42$, $p=0.018$).

Discussion: The study highlights substantial variability in training quality across sites. Several priority improvements were identified : structured supervision models, clearer learning objectives, protected time for academic tasks, and better regulation of workload.

Conclusion: While most training sites are well perceived, significant disparities persist. Strengthening supervision, formalising feedback processes, and enforcing workload standards could enhance the overall quality and equity of GP training.

ID 629- Making thesis learning meaningful: Using storytelling to humanise online education in general practice

Alexis MOUTHON [(1)] , Hubert MAISONNEUVE [(2)], Anne-Laure MUTIN [(3)]

(1) University Of Grenoble, Grenoble, France
(2) University Of Geneva, Geneve, Suisse
(3) University Of Lille, Lille, France

Context: Learner engagement is critical when designing effective distance learning programmes. This study takes place in an online program about thesis learning in the context of general practice. The project aims to provide resources to medical residents and their research supervisor from the initial selection of a thesis topic to the final defence. It involves in the creation of a high-quality narrative to improve educational scriptwriting, with storytelling being one of the tools mentioned for this purpose.

Objectives: This study explored how storytelling influences motivation among general practice residents enrolled in a distance learning module on thesis writing ("Thèse XXX").

Methods: We conducted a qualitative study using semi-structured interviews with 16 general practice

residents (XXX region, XXX; July–October 2025). Participants were interviewed before and after viewing two instructional videos on thesis problematisation: one using traditional didactic presentation and one employing narrative storytelling techniques. Data were analysed using the Framework Method, guided by the COM-B model of behaviour change and Bandura's social cognitive theory. We used a phenomenological approach.

Results: Most participants regularly consumed video content for entertainment. Competing time demands from personal and professional obligations emerged as major barriers to online learning engagement. Prior to video exposure, participants held no strong preconceptions about storytelling as a pedagogical tool. Following video viewing, the narrative approach was associated with enhanced motivation, greater perceived agency, and increased intention to engage. The storytelling video was perceived as more reassuring through its step-by-step approach and fostered a sense of proximity to the department. Compared with the traditional video, it generated stronger learner identification and sustained attention, with the content perceived as less academically intimidating.

Discussion: Whilst theoretical frameworks support fictional design in medical education, the author's inexperience in qualitative research and video creation may have constrained this study's effectiveness. Storytelling builds proximity and scaffolding for gradual discovery. The digital ecosystem has evolved considerably, with AI tools now transforming the learning landscape.

Conclusion: Storytelling shows promise for enhancing engagement in distance medical education. However, its integration requires careful consideration of learner context, content design, and institutional support structures. Further research is needed to assess behavioural outcomes and transferability across educational settings.

Corresponding author: Alexis Mouthon, alexis.mouthon@univ-grenoble-alpes.fr

ID 469- Supporting Post-Graduate Medical Students in Thesis Completion: Evaluating a Digital Matching Platform – A Mixed-Methods Study

Hind MACHKOUR, Dragos-Paul HAGIU, Bilal KALAY, Aurélien FALCON, Stephane BOUXOM

Departement De Médecine Générale, Saint-Etienne, France

Context: The general practice thesis represents a major challenge for the french third-cycle medical students. Connecting postgraduate medical students (E3C) with thesis supervisors is a key challenge in general practice education. Digital matchmaking platforms, such as Adopteunethese.fr, offer potential solutions to address this issue.

Objectives: This study aims to evaluate the efficiency and acceptability of this tool by analyzing user satisfaction and identifying areas for improvement.

Methods: A convergent mixed-methods cross-sectional study was conducted, combining usage data from the platform, a quantitative evaluation using the System Usability Scale (SUS), and qualitative insights from focus groups. Participants included E3C students and postgraduate physicians.

Results: The platform has 1,132 registered members, 119 thesis projects submitted, and 60 successful matches. The average SUS score of 81.11 indicates a high level of user satisfaction. Usage analysis reveals a disparity between projects submitted by supervisors and students. Supervisors' projects receive more applications (116 vs. 23, $p<0.001$) and lead to more successful matches (43 vs. 17, $p<0.001$). The focus groups confirmed the perceived usefulness of the platform while highlighting key areas for improvement

Discussion: This study highlights both the advantages and limitations of a digital platform designed to facilitate the matching of general practice thesis students and supervisors. Usage behavior analysis reveals active participation from supervisors, but reduced visibility of student-submitted projects, indicating a mismatch that could be addressed through better student project promotion tools. This evaluation underscores the importance of developing platforms tailored to users' specific needs and integrating them into a cohesive national framework.

Conclusion: This study illustrates the relevance of evaluating digital matchmaking tools such as Adopteunethese.fr, not only to ensure their efficiency but also to guide their continuous improvement. As the adoption of digital solutions becomes increasingly widespread, rigorous evaluations are essential to better understand their impact on academic collaboration and to inform their integration into complex educational environments.

ID 367- Implementation of "all-inclusive" internships for medical students in rural areas: issues, challenges and potential solutions

Dominique HENRION

Université De Namur, Namur, Belgique

Context: The evenings are the place for the internship programs and the rural environment, including transportation, supervision and community integration. This program is designed to help you develop your general medical skills and enhance your perception and experience of your appreciation of the environment in rural areas, which is part of the principle of the conditions for viewing and developing positive influencer positives based on your choice of specialty and encouragement to develop your career and your rural knowledge.

Methods: An exploratory action-research project was conducted over a one-year period. Data collection methods included semi-structured interviews and field observations, allowing for a qualitative analysis of the experiences of trainees, supervisors, and the municipalities involved.

Originality: Our initiative is part of the rural educational pipeline described by Pong et al., while addressing the difficulties young students face in completing internships in rural areas, namely housing and transportation. We therefore created “all-in” internship

Lessons learned and future implication: Experience shows that local political commitment, the mobilization of logistical resources, and the motivation of supervising physicians are key determinants of success. Conversely, professional resistance, organizational tensions, and political uncertain

Discussion: Despite these initial encouraging results, political, economic, and human obstacles remain, including resistance to change and a lack of coordination between the different stakeholders. A structural strategy could include increased funding for physicians’ associations and strengthened collaboration with municipalities, in order to ensure ongoing support for interns. In the medium and long term, more pooled and sustainable models—such as shared housing in semi-rural centers with interns distributed across several neighboring municipalities—could increase the program’s effectiveness and durability. Future prospects include expanding this model to other regions and professions to meet the growing needs of rural communities.

Conclusion: Our model offering internships in rural settings has been met with strong enthusiasm and addresses the issues of medical shortages in rural areas. Early feedback is encouraging. Nevertheless, obstacles remain, and further implementation measures will be needed to advance this strategy.

ID 2024- Barriers to morphine prescription in primary healthcare: results of a survey among family doctors

Erkinai BOTBAEVA [(1)] , Anara KOSHUKEEVA [(1)], Beyeler YVES [(2)], Turgunalieva MILANA [(3)]

(1) I.k. Akhunbaev Kyrgyz State Medical Academy, Bishkek, Kirghizistan
(2) Maurice Foundation, Geneva, Suisse
(3) Assosiation Of Palliative Care, Bishkek, Kirghizistan

Context: Morphine is the key medication for managing severe pain, especially in patients requiring palliative care. Despite regulatory changes aimed at improving access to opioid analgesics, Morphine remains underused in primary

healthcare. Exploring physicians' awareness and the barriers to its prescription is crucial to improving pain management practices.

Objectives: To assess the frequency of morphine prescription and the level of awareness among primary care physicians regarding standard practices and recent regulatory changes.

Methods: A quantitative cross-sectional study was conducted using an online questionnaire (Google Forms). A total of 107 physicians from all regions of the Kyrgyz Republic participated. Most respondents were family doctors (N = 89), with general practitioners also represented (N = 13). The survey collected information on demographics, professional status, knowledge of the WHO pain ladder, morphine prescribing practices, and awareness of Government Decree No. 572 (dated 8 September 2025), which regulates the prescription of narcotic and psychotropic drugs. (Descriptive statistics were used for data analysis)

Results: The mean age of respondents was 46.5 ± 12 years, with 98 women. Although 86 reported being familiar with the WHO pain ladder, only 16 prescribed Morphine, mostly rarely or monthly. The main reasons for not prescribing Morphine were absence of patients requiring it (63/84), fear of responsibility (11/84), and insufficient knowledge (10/84). 62 respondents reported having only partial knowledge of practical guidance on Morphine use. Notably, 38 physicians were unfamiliar with the new Decree No. 572, and an additional 33 were only partially familiar with its content. The most frequently cited concerns were potential side effects (48) and risk of patient addiction (37). When Morphine was unavailable, 80 relied on non-opioid analgesics.

Discussion: The findings reveal a significant gap between physicians' theoretical awareness and practical use of Morphine. Despite the updated legal framework, concerns, lack of training, and limited access to clear clinical guidance remain major barriers.

Conclusion: To improve access to adequate pain relief in primary care, targeted educational initiatives, better dissemination of regulatory updates, and the development of practical clinical guidelines for family doctors are essential.

ID 1919- Narrative review of the literature concerning the effects of marine collagen on osteoarthritic joint pain

Myriam ELOUARIAGHLI [(1)] , Eloise ZAIRI [(1)], Claude BRONNER [(2)]

(1) Université De Versailles, Montigny Le Bretonneux, France
(2) Université De Strasbourg, Strasbourg, France

Context: Osteoarthritis is a common joint disease causing chronic pain and impaired quality of life. Given the limitations of conventional therapies (NSAIDs, analgesics, non-drug treatments), marine collagen, a natural nutraceutical, has gained growing interest for its potential effects on joint pain.

Objectives: This narrative review aims to summarize available experimental studies about the effects of marine collagen hydrolysates on osteoarthritic joints, focusing on tolerance, joint pain and mobility, on joint cells, inflammatory mediators, and cartilage structure.

Methods: A narrative literature review was conducted using PubMed, Scopus, and the Cochrane Library, along with grey literature analysis. Included studies assessed supplementation with marine-derived collagen in osteoarthritis or joint pain. Among 438 articles, 16 experimental studies were retained including 6 clinical and 10 preclinical studies.

Results: Clinical studies generally reported reduced joint pain and improved joint function, with good overall tolerance of marine HC. Safety appeared well-established, with no evidence of pathogen transmission. Preclinical studies (in vivo and in vitro, using human or animal models) highlighted beneficial effects on cartilage matrix integrity, inflammatory mediators, and biomarkers. However, two of the preclinical studies, mainly conducted ex vivo, have shown paradoxical effects, depending on hydrolysate fraction size and concentration.

Discussion: Clinical results are encouraging but heterogeneous ; as tested products were extracted from different, not always comparable, sources. Studies also differed in analytical methods and methodological quality. Some preclinical studies

showed variable results, depending on hydrolysate concentration, source, and extraction method. Although ex vivo findings have limited clinical transposability, they suggest that the effects of one hydrolysate preparation cannot be extrapolated to others. Therefore, defining a HC as a safe and effective nutraceutical requires thorough evaluation of its pleiotropic effects.

Conclusion: The available data do not yet allow firm conclusions regarding the specific efficacy of all marine HC in osteoarthritis. Nevertheless, this review highlights preliminary biological and clinical evidence suggesting potential benefits in certain cases. Well-designed randomized, double-blind clinical trials with standardized formulations, defined populations, and long-term follow-up are required to confirm efficacy, safety, and indications.

ID 1855- Impact of secured prescription requirements on zolpidem and pregabalin dispensing in France, 2014–2024

Lucile PIRAULT, Laëtitia GOSSELIN

Université Paris Cité, Paris, France

Context: In France, secured prescriptions have been mandatory since 2000 for drugs classified as narcotics. In response to increasing reports of abuse, misuse and dependence, secured prescription requirement were extended to zolpidem in 2017 and to pregabalin in 2021.

Objectives: This study aimed to assess the impact of these secured prescription requirements on the dispensing of zolpidem and pregabalin in France between 2014 and 2024.

Methods: We conducted an observational, cross-sectional study, using Open Medic, an open-access annual database providing reimbursement information on drugs dispensed in pharmacies. The study population included all patients dispensed zolpidem or pregabalin in France between January 1, 2014, and December 31, 2024.. The primary outcome was the annual number of zolpidem and pregabalin packages dispensed. Stratified analyses were performed according to age group, gender and prescriber specialty. Negative control drugs not requiring secured prescriptions (zopiclone and gabapentin) were included for both substances to assess potential substitution.

Results: Between 2014 and 2024, the number of zolpidem packages dispensed in France decreased from 19,812588 to 5,780,872 (-70%) with the largest decline occurring between 2016 and 2018. In comparison, zopiclone dispensing increased during this period, mirroring the decrease in zolpidem, although to a lesser extent (+21% between 2016 and 2018). For pregabalin, the number of packages increased between 2014 and 2020 (+28%), followed by a decline until 2024 (-29%) resulting in fewer packages dispensed in 2024 than in 2014. Gabapentin dispensing increased between 2014 and 2020 (+28%), with a more pronounced rise from 2020 to 2024 (+50%), coinciding with the introduction of secured prescription requirements for pregabalin.

Discussion: The temporary increase in zopiclone dispensing contrasts with the continued rise in gabapentin, which may be explained by the 2021 recommendation designating gabapentin as a first-line treatment for neuropathic pain. Overall, the secured prescription measure appears to be effective in the long term. Clonazepam, which has required secured prescriptions since 2011, also showed a continuous decrease in dispensing over time, with a 31% reduction over 10 years.

Conclusion: The introduction of secured prescription requirements resulted in a reduction in zolpidem and pregabalin dispensing with limited substitution to alternative drugs.

ID 1729- Factors influencing general practitioners' decisions to prescribe medical cannabis in Occitanie

Clémence VACHER, Marie-Hortense CALMON

Toulouse, Toulouse, France

Context: In 2019, France launched a national pilot program to introduce medical cannabis for selected indications, such as refractory neuropathic pain or intractable symptoms in oncology, under the supervision of the French National Agency for Medicines and Health Products Safety (ANSM). Prescribing was initially restricted to referral centers, with the possibility of continuation by general practitioners (GPs). However, uptake of medical cannabis prescribing in primary care has remained limited.

Objectives: The primary objective was to explore the factors influencing GPs' decisions to potentially prescribe, or not prescribe, cannabis.

Methods: Our study used a design with semi-structured interviews, followed by a grounded analysis. Participants were GPs practicing in primary care in Occitanie, including both physicians involved in the national pilot program and those who were not prescribers. Analysis followed an iterative comparative process with coding and theme development until thematic saturation reached.

Results: Medical cannabis generated significant expectations among participants, particularly regarding pain relief in situations where conventional treatments had failed and as a potential means to reduce opioid analgesic use. Clinical judgment was constructed through training and review of the scientific literature, but above all through feedback from treated patients, which played a central role in influencing prescribing attitudes.

Discussion: The perceived analgesic benefit of medical cannabis remains insufficiently demonstrated in the current literature, which echoes participants' simultaneous hope and doubt. Future prescribing frameworks in France will need to take into account existing difficulties in accessing specialist care, which may limit the feasibility of highly specialized prescribing models. In this context, international experiences and established national prescribing pathways may provide useful guidance. Although the risk of dependence and misuse is more clearly documented for recreational cannabis, participants considered these risks relevant in medical use as well, supporting the need for regulatory and monitoring measures accompanying any

Conclusion: GPs' acceptance of medical cannabis appears to rely on a balance between expected therapeutic benefit and concerns. These findings highlight the importance of scientific evidence, appropriate regulation, and education to support the future integration of medical cannabis into primary care practice.

Corresponding author: Marie-Hortense Calmon, mh.calmon@gmail.com

ID 548- Experimentation with medical cannabis as social transformation in the field of health

Abigaël HASSLER, Nadine PELLEN, Lucas BEURTON-COURAUD, Morgane GUILLOU-LANDREAT

Chu Brest, Brest, France

Context: Since 2021, France has been conducting an experiment with medical cannabis under the auspices of the ANSM, involving general practitioners and hospital doctors, community and hospital pharmacists, and patients. After completing training, professionals are authorized to prescribe and dispense medical cannabis to treat refractory neuropathic pain, painful spasticity, refractory and drug-resistant epilepsy, palliative situations, and intractable symptoms in oncology.This experiment has already given rise to several studies, mainly theses by medical interns, focusing on obstacles, facilitators, and representations. This research, conducted in partnership with the ANSM, remains above all pragmatic in order to make empirical observations about the experiment.

Objectives: This study aims to show that a psychosocial approach can shed light on the mechanisms underlying the results targeted by medical cannabis trials.

Methods: It uses a qualitative secondary analysis method applied to a large existing corpus: 194 semi-structured interviews and 8 focus groups conducted by interns as part of their general medicine theses. The homogeneous sample includes healthcare professionals and patients involved in the trial. The phenomenologically inspired analysis consists of a sociopsychological re-reading of these materials in order to examine how medical cannabis influences identities, standards of care, and the place of this subject at the intersection of medicine, politics, and lived experience.

Results: The results, currently being compiled, should show that concepts from social psychology and sociology - identity, norms, representations, social roles, boundary objects - can reveal the multidimensional issues at stake in this experiment, whether medical, political, identity-related, normative, or representational.

Discussion: The general hypothesis is that the experiment goes beyond the simple introduction of a new treatment: it reveals tensions between knowledge, norms, and identities in the field of health, reconfigures social roles, brings about new identity affiliations, and forces actors to negotiate meanings in an uncertain symbolic space.

Conclusion: To our knowledge, no study has addressed experimentation from a psychosocial perspective, even though it is not limited to therapeutic innovation: it acts as a vector of social transformation within the health field.

ID 269- Adverse drug reaction in primary care

Sofiane BELKACEM

Doctor, Paris, France

Context: The consumption of outpatient medications continues to grow in France. This can lead to adverse drug reactions (ADRs), some of which are predictable and preventable. But it also carries a risk of iatrogenic medication, which is the cause of morbidity, mortality and high healthcare costs. This is a major challenge as it is the second leading cause of serious preventable adverse events in healthcare.

Objectives: The objective of this study was to estimate the prevalence of medication-related causes of complaints reported during consultations among adult patients in the Ile-de-France region in 2024.

Methods: This was an observational, non interventional, cross-sectional, descriptive, quantitative study using a completely anonymous questionnaire administred to patients over the age of 18 in the Ile-de-France region. The questionnaires were completed retrospectively by four different investitagors, all of whom were general medicine interns at Sorbonne Paris Santé University.

Results: We analyzed a total of 1000 patient prescriptions. Of these, 105 (10.5%, 95% CI : 9-11%) came to see us for a reason identified by our approach as a possible adverse drug reaction. The most frequently implicated drug class was antihypertensives (28,5% n=51). Patients with potential ADRs consumed significantly more drugs, were generally older and more drug interactions in their prescriptions. Finally, using a logistic regression model, we found that advanced age significantly increased the risk of potential ADRs in patientsaged 50-65 (OR : 5.47 p-value < 0.022) and aged 66-80 (OR : 6.63 p-value < 0.013), while polypharmacy significantly increased this risk by 14% (p< 0,008).

Discussion: Factors that could influence the occurence of these adverse drug reactions were : polypharmacy, advanced age and drug interactions. Our approach to detecting adverse effects is part of quaternary prevention to enrich our prescribing practices and reinforce actions promoting the proper use of medications and coordination between prescriptions from different healthcare professionals.

Conclusion: General practitioners are experts on their patients. This has enabled us to identify areas for improvement in our practice with regard to polypharmacy and drug interactions particularly among our oldest patients.

ID 213- Efficacy of opium extract analgesics (Izalgi® and Lamaline®) : a systematic review of Randomized Clinical Trials and analysis using the REB method

Marion MONTELLIER, Boussageon RÉMY

Université Lyon 1, Lyon, France

Context: Opium extract-based medications (Lamaline® and Izalgi®) are opioid analgesics classified as level 2 according to the World Health Organization (WHO). In the context of proper use of analgesics, especially opium derivatives, and considering the issues raised globally, it is important to question their usage.

Objectives: This work wanted to evaluate the effectiveness of these opium extracts in primary care.

Methods: This is a systematic review of the literature to assess the effectiveness of opium extract (Lamaline®, Izalgi®) in pain management regardless of its origin. This review adhered to PRISMA guidelines. The bibliographic search was conducted until 18/07/2024 in the four main databases (Medline - PubMed, Embase, Cochrane Central Register of Controlled Trials - CENTRAL, and ClinicalGov.org) using the following MeSH terms: “opium extract,” “opium powder,” “lamaline,” or “izalgi.”

Results: The bibliographic search led to the inclusion of a single phase III multicenter, randomized, double-blind, non-inferiority trial. The analysis of this trial using the Rob2 tool identified a risk of bias. According to the REB method, there is no evidence of effectiveness of the use of opium extract in pain relief.

Discussion: There appears to be a lack of published data on the use of opium-extract analgesics. Therefore, in the era of evidence-based medicine (EBM), it is legitimate to question the prescription of analgesics such as opium derivatives due to the lack of solid data demonstrating their effectiveness. This study did not identify sufficient evidence (whether convincing or not) to recommend the prescription of Izalgi® or Lamaline® for any type of pain, particularly considering their side effects.

Conclusion: These results justify reconsidering the prescription of opium extracts for pain management. High quality clinical trials are needed to provide a solid level of evidence for the effectiveness of opium exract in pain treatment.

ID 1644- The “Mon soutien psy” Program in the Management of Socio-Economically Disadvantaged Patients with Anxiety–Depressive Disorders.

Emilie MOSSER, Gilles LAZIMI

Paris, France

Context: Psychological issues are common in general practice consultations. Psychotherapy is the first-line treatment for mild to moderate anxiety–depressive disorders. Access to psychotherapy remains limited, and additional barriers affect socio-economically disadvantaged patients (system saturation, stigma, compartmentalized care pathways, reduced mobility). The “Mon soutien psy” program, implemented in April 2022 (revised in June 2024), aims to facilitate such access. Its utility in the follow-up of socio-economically disadvantaged patients has not yet been evaluated.

Objectives: To gather general practitioners’ evaluations of the “Mon soutien psy” program in the management of socio-economically disadvantaged patients in the Paris region in 2024.

Methods: A qualitative grounded theory study was conducted among self-employed and salaried general practitioners working in disadvantaged districts of Paris and its suburbs. Data were collected through semi-structured individual interviews continued until data saturation was reached. A constant comparative analysis was performed. Consent was obtained for participation in the study and for audio recording.

Results: Fourteen general practitioners were interviewed (6 in private practice, 8 salaried). According to the general practitioners, the program is useful in the management of socio-economically disadvantaged patients, providing an alternative to follow-up with private psychologists or with other pre-existing structures (e.g., community mental health centers). Several barriers to access for disadvantaged patients were reported: a limited number of participating practitioners, difficulties

accessing information, upfront payment requirements, language barriers, and digital illiteracy.

Discussion: Some of the limitations mentioned in this study had already been identified in the literature, including difficulties in obtaining appointments and the fact that the program reaches only a limited segment of the patient population. The issue of access related to language barriers is not specific to this program; it is a common challenge in medical practice and constitutes an obstacle to care. This highlights the relevance of transcultural psychotherapy and ethnopsychiatry services.

Conclusion: Although the program is generally well received by physicians, they nonetheless call for improvements to strengthen its role in the management of socio-economically disadvantaged patients: broader inclusion criteria and measures to encourage psychologists to participate.

Corresponding author: Emilie Mosser, dr.emilie.mosser@gmail.com

ID 1832- Use of service and forgone care in medical students in France : A nationwide study

François VILAIN [(1)] , Nicolas DOUDEAU [(2)], Kahina SADAT [(3)], Juliette DANCKAERT [(4)], Yannick MORVAN [(5)], Ariel FRAJERMAN [(6)]

(1) Dr, Nantes, France
(2) Dr, Lille, France
(3) Dr, Versailles, France
(4) Dr, Montpellier, France
(5) Dr, Paris Nanterre, France
(6) Dr, Paris, France

Context: Many studies have found a high prevalence of depression in medical students, but there are few data on the use of care.

Objectives: Our goals were to assess the prevalence of service use and adequate treatment in medical students suffering from depression, to explore the prevalence and reasons for foregoing care, and to compare data from 2021 and 2024.

Methods: In 2024, a national online survey of French medical school students and residents of all specialities was conducted. The Composite International Diagnostic Interview Short-Form questionnaire assessed 12-month Major Depressive Disorder (MDD); 12-month service use and pharmacotherapy were evaluated. We also studied the prevalence and reasons for foregoing care, as well as the type of psychotherapy.

Results: 7640 medical students were included, 30% suffering from MDD. Only half of the medical students with MDD received adequate treatment. Among those reporting psychotropic medications, 1 in 5 used their hospital service's pharmacy and 1 in 10 self-prescribed anxiolytics. Use of services increased between 2021 and 2024 (30% to 50%), with more access to psychotherapy and a stable level of pharmacological treatments in 2024. Among students who consulted a “psy”, 1 in 5 declared they didn’t have sufficient sessions. Delivered psychotherapies were mainly cognitive behavioural therapy (32%) and psychoanalysis (10%). The main reason for not seeking psychotherapeutic help was the financial burden (23%).

Discussion: The study had strengths: the large number of students (>5000) and the increased number of questions regarding the use of care and the reason for not using care. However, this study also had limitations. First, the response rate was low (<10%) and lower than the 2021 survey. Second, we didn’t have information about the duration of psychotherapy or pharmacotherapy, with a risk of overestimating the prevalence of adequate treatment.

Conclusion: To our knowledge, this is the largest and most complete study on care use in medical students. It highlighted the improvement of treatment for MDD in this population, but also the need for complementary actions because only half of the students with MDD received adequate treatment.

Corresponding author: François Vilain, francoisvilain3@protonmail.com

ID 705- Major depressive disorder among general practice residents: prevalence and proposed strategies to improve psychological well-being at the University of Lille

François QUERSIN, Joanna FLAMAIN

University Of Lille, Lille, France

Context: Psychological distress among medical students is a major public health concern with demonstrated consequences for care quality, medical errors, and professional sustainability. National data show high rates of anxiety and depression among XXX medical students. Local studies in XXX revealed high levels of burnout risk and anxiety among general practice residents. The prevalence of major depressive episodes (MDE) and residents' preferences for improvement strategies remain insufficiently explored.

Objectives: The primary objective was to estimate the prevalence and severity of MDE among general practice residents at XXX University. The secondary objective was to identify residents' priorities and expectations regarding preventive, screening, and support interventions to address psychological distress during residency.

Methods: A descriptive cross-sectional monocentric study was conducted in 2023 among general practice residents at XXX University. An anonymous online questionnaire included sociodemographic variables, general psychological indicators, and the Composite International Diagnostic Interview–Short Form (CIDI-SF) to assess MDE during the preceding 12 months. Opinions regarding potential interventions were collected using five-point Likert scales. Descriptive statistics and chi-square tests ($p < 0.05$) were applied.

Results: Among 123 respondents, 52% reported significant psychological difficulties during residency. A total of 22.8% met CIDI-SF criteria for MDE, predominantly moderate (53.6%) or severe (42.9%), and 17.9% presented subsyndromic depressive states. Residents expressed broad support for multiple improvement strategies: – Strengthened resident training on stress management, coping with medical errors, end-of-life care, and psychosocial risks (80–90% approval). – Enhanced pedagogical, managerial, and psychosocial risk-awareness training for supervisors in ambulatory and hospital settings (70–85%). – Strict enforcement of working-time regulations and expansion of ambulatory training positions (>90%). – Implementation of a departmental well-being unit and identification of a quality-of-life referent (≈80%). – Clear, repeated dissemination of information regarding available mental-health structures (≈90%). – Strong preference for an independent psychological support service, outside the academic validation structure (82.9%).

Discussion: The high prevalence of depressive symptoms underscores substantial psychological vulnerability. Residents' proposals emphasize structural reforms, institutional responsibility, and the need for psychologically safe and independent access to care.

Conclusion: General practice residents experience considerable psychological distress. Their recommendations highlight actionable priorities for improving prevention, screening, and support systems, thereby contributing to safer training environments.

ID 375- Hypnotherapy and anxiety disorders: a narrative review of the literature

Sarah Lou MAMOUNE, Clémence FOUQUET

Université De Rennes, Rennes, France

Context: Hypnotherapy is increasingly used in general medicine in XX to manage psychological conditions such as anxiety. Several studies support its effectiveness in reducing anxiety symptoms. However, evidence regarding the efficacy of hypnotherapy as a stand-alone intervention remains limited, as hypnosis is often combined with other psychological approaches such as cognitive-behavioural therapy.

Objectives: Description of the hypnosis methods reported in studies discussing hypnotherapy alone for the treatment for anxiety disorders (techniques used, session procedure, duration of therapy, individual or group sessions, use of self-hypnosis).

Methods: We conducted a narrative review using systematic review methods, focusing on treating anxiety with hypnosis. Searches were performed in PubMed, PsycINFO, and Cochrane databases and Google scholar. The search strategy was based on mesh terms. The search equation was : ("Hypnosis"[Mesh]) AND ("Anxiety Disorders"[Mesh]) ; ("Hypnosis"[Mesh]) AND

("general anxiety disorder" [Supplementary Concept]) ; ("Hypnosis"[Mesh]) AND ("Phobic Disorders"[Mesh]) ; ("Hypnosis"[Mesh]) AND ("Panic Disorder"[Mesh]) ; ("Hypnosis"[Mesh]) AND ("Agoraphobia"[Mesh]) ; ("Hypnosis"[Mesh]) AND ("Phobia, Social"[Mesh]). The inclusion criteria were: original articles in English or French, articles addressing hypnotherapy in the treatment of anxiety disorders in patients over 18 years of age. PRISMA Flowchart was used. SANRA tool were applied.

Results: Among the 18 included articles, only one was a randomized clinical trial. While a few well-described methods were identified for panic or phobic disorders, the remaining studies revealed substantial heterogeneity in methodology, with procedures for anxiety disorders often poorly documented. Protocol standardization is lacking concerning group modality, session number, and the use of self-hypnosis.

Discussion: These findings are consistent with those observed in other clinical indication, such as insomnia. This review may help researchers identify and refine existing hypnosis methods in this field. It also highlights the need to publish precise, standardized hypnotherapy protocols prior to assessing their effectiveness.

Conclusion: This narrative review highlights the methodological obstacles to clinical trial implementation, primarily related to the absence of standardized protocols and the lack of a recognized gold standard hypnotherapy method. We proposed IDEAL framework, which recommends research steps to evaluate one specific non-pharmacological therapy. This approach may support future clinical trials aiming to assess the effectiveness of a standardized hypnosis method.

Corresponding author: Clémence Fouquet, fouquetclemence@hotmail.com

ID 335- Efficacy of combined eschscholtzia and valerian extracts in alleviating insomnia associated with anxiety: a randomized, double-blind, placebo-controlled trial

Samira AIT ABDELLAH [(1)] , Claude BLONDEAU [(1)], Caroline GAL [(1)], Sylvie COPINE [(2)], Marine BUCHET [(2)], Valérie DORMAL [(2)], Alessandra CERVINO [(1)], Isabelle GUINOBERT [(1)], Emmanuelle BOCANDÉ [(1)], Patrick LEMOINE [(3)]

(1) Pileje, Paris, France
(2) Center Of Investigation In Clinical Nutrition, Catholic University Of Louvain, Louvain-La-Neuve, Belgique
(3) Centre Médico-Psychologique Pour Adultes (cmpa) De Villefontaine, Villefontaine, France

Context: Pharmacological options to alleviate insomnia — benzodiazepines, “Z drugs”, and others — can all have significant undesirable effects, such as addiction or interaction with other medications, raising concerns for long-term use. Given the worrying side effects and risks, it is recommended to prescribe them as a second-line treatment, and physicians and patients often turn to non-pharmacological or over-the-counter drugs such as herbal medicines.

Objectives: The objective of this study was to evaluate the efficacy of a supplement comprising eschscholtzia and valerian extracts in alleviating insomnia associated with anxiety.

Methods: This was a double-blind, randomized, placebo-controlled study conducted in adults (n=84) with an Insomnia Severity Index (ISI) score ≥ 15 and a Hamilton Anxiety Rating Scale (HAM-A) score > 8 and < 25 at inclusion. Participants received three tablets per day of either the supplement (containing 120mg of eschscholzia plus 50mg of valerian per tablet) or a placebo from day (D) 7 to D35, with follow-up until D57. Sleep habits were assessed daily using an actimeter and an electronic sleep diary, ISI and HAM-A scores being determined on D7, 36 and 57.

Results: On D36, reductions in ISI scores were significantly greater in the supplemented group versus the placebo group (6.21 ± 4.91 [95%CI -7.82; -4.60] vs 3.89 ± 4.45 [95%CI -5.21; -2.57], p=0.030), as were reductions in HAM-A scores (6.24 ± 6.45 [95%CI -8.36; -4.12] vs 3.57 ± 5 [95%CI -5.28; -1.85], p=0.049). No between-group difference was statistically significant on D57. No severe adverse events or supplement-related adverse events were reported. Most of the patients had no difficulty in stopping the allocated supplementation (86.8% with supplement vs 100% with placebo, p > 0.05) and the majority reported no withdrawal symptoms (97.4% vs 95.5%, p > 0.05).

Discussion: Exploratory analyses indicated changes in intestinal microbiota composition with

the supplement, suggesting possible involvement of the gut-brain axis in its beneficial effects on sleep.

Conclusion: The tested supplement improved sleep quality, reduced associated anxiety and was well tolerated, supporting its consideration as a therapeutic option for relieving insomnia. Supplement discontinuation was easy; this plant-based product could therefore be used as an interesting alternative to conventional pharmaceutical treatments.

ID 299- Gender influences in primary care management of depressive disorders: a qualitative study among general practitioners

Aurore TRAMEÇON [1] , Elsa VILLALON [2]

(1) Ur7479 Spurbo, Département De Médecine Générale, Université De Bretagne Occidentale, Brest, France
(2) Université De Bretagne Occidentale, Brest, France

Context: Depressive disorders are highly prevalent in primary care. Gender, understood as a social and cultural construct shaping norms, behaviors, and expectations, influences both the expression of depressive symptoms and how they are interpreted by clinicians. Yet little is known about how gender representations influence diagnostic reasoning and management in general practice. Understanding these mechanisms is crucial to reducing inequities in care. This study explored how general practitioners (GPs) perceive and integrate gender in their approach to depressive disorders.

Objectives: To explore the influence of GPs' gender-related representations on the identification, interpretation, and management of depressive disorders in primary care in the XXX.

Methods: A qualitative study using semi-structured interviews was conducted with GPs recruited from diverse practice settings. The interview guide explored perceptions of depressive symptoms in relation to the gender of patients and the physicians' own professional positioning. Interviews were transcribed verbatim and analyzed using a general inductive approach to allow themes to emerge from the data.

Results: Gender representations deeply shaped the clinical process at every stage. For women, GPs associated depressive symptoms with multidimensional social pressures — family responsibilities, professional demands, body image norms — and with higher exposure to sexual violence. For men, the social expectation of emotional restraint and strength led to reduced expression of distress and to compensatory behaviors such as alcohol use, social withdrawal, or irritability, often masking underlying depression. These contrasting patterns led to differentiated care pathways: while men were often underdiagnosed despite a perceived higher suicide risk, GPs reported a tendency to medicalize and hospitalize women more frequently. Although participants expressed a desire for neutrality, they acknowledged the persisting influence of implicit gender biases and described adaptive strategies with variable success.

Discussion: Findings show how gendered expectations influence clinical interpretation and contribute to inequities in the diagnosis and treatment of depressive disorders. Addressing these biases is essential to improve diagnostic accuracy and aligning care with actual patient needs.

Conclusion: This study highlights a pattern of overmedicalization among women and underdiagnosis among men. Increasing awareness of gender bias is essential to ensure equitable care and reduce preventable disparities, particularly regarding suicide risk.

ID 262- Lived Experiences of General Practitioners in XXX Regarding Suicidal Behaviors Among Farmers

Mathilde MINET, Alexandre PAUC

Dumg Montpellier, 48000, Mende, France

Context: Farmers exhibit a significantly increased risk of suicide despite an overall lower mortality rate. General practitioners are identified by these

patients as their primary source of healthcare. XXX is a rural area characterized by small livestock farms, both recognized as risk factors.

Objectives: To explore the experiences of general practitioners in XXX regarding suicidal behaviors among farmers.

Methods: A phenomenological qualitative study was conducted with nine general practitioners practicing in XXX. Data were collected through individual semi-structured interviews using an interview guide.

Results: Farmers are described as reluctant to seek care and rarely consult for psychological issues. The trajectories analyzed reveal multiple contributing factors: psychiatric (depression, alcoholism, impulsivity), psychosocial (isolation, administrative burden, economic insecurity), and family-related (inheritance conflicts, pressure to take over the farm). Suicidal acts are portrayed as violent and impulsive. Faced with these risks, physicians systematically screen for suicidal ideation but encounter barriers such as stigma surrounding mental health care and lack of resources. They report feelings of profound helplessness and perceive suicides as personal failures.

Discussion: Suicide prevention is already difficult in the general population. The complexity of this care lies in the fact that patients are distant from care and uncomfortable admitting that they have a mental health problem. We must reach these populations in difficulty. We must develop local resources and be familiar with them in order to easily refer patients.

Conclusion: These findings highlight the complexity of suicidal behaviors in this population and the challenges of their management. The study underscores the need for a multidisciplinary and locally adapted approach to better guide farmers toward appropriate care.

ID 1985- Level of physical activity among children aged 18 months to 4 years attending healthcare facilities in the Île-de-France region in 2024/2025

Cecilia SALDANHA GOMES, Aurore BANCET

Sorbonne Université, Paris, France

Context: Physical activity (PA) plays a key role in children's overall development. WHO recommendations specify the duration and intensity of PA required for children aged 0 to 5 years. Factors such as sensory disorders or pet ownership may influence the level of PA in young children.

Objectives: The aim of this study is to describe the level of PA among preschool children attending healthcare facilities in the Île-de-France region and to analyze its link with their psychomotor development and sociodemographic profile.

Methods: This is a multicenter study conducted using a self-administered questionnaire completed by parents of children aged 18 months to 4 years. It is divided into four sections : sociodemographic characteristics, medical information, psychomotor development and assessment of physical and sedentary activity using the EY-PAQ questionnaire. Bivariate analyses (Student's t-tests and ANOVA) explored the associations between PA, sedentary behavior, and the identification of a neurodevelopmental disorder on the one hand, and sociodemographic factors on the other. Linear and logistic regressions were then used to adjust these relationships, taking into account the identified confounding factors. The data were processed using Excel and R++, with a significance threshold set at 0.05.

Results: The recruitment period runs from October 2024 to February 2025. Our study population includes 311 children, 52% of whom are boys. Children engaged in an average of 155 minutes per day of moderate to vigorous PA and 219 minutes per day of sedentary activity. Lower levels of moderate to vigorous PA are significantly associated with the identification of neurodevelopmental disorders. Low parental education and the presence of a dog in the household are associated with higher levels of PA. A positive correlation between PA and sedentary behavior was also observed.

Discussion: Our study highlights levels of PA are consistent with WHO recommendations, but much higher levels of sedentary activity. The positive association between PA and sedentary activity requires further studies using profile-based approaches. Children suspected of having neurodevelopmental disorders should receive special support in their PA.

Conclusion: PA for preschool children requires both parental support and policies to prevent sedentary lifestyles.

ID 1681- Taking care in complex situations: better prioritisation using the GOC approach

Laetitia BURET [(1)] , Isabelle HEYMANS [(1)], Helene KERSTENS [(1)], Jean-Luc BELCHE [(1)], Gilles COLEMONTS [(2)]

(1) Université De Liège, Liège, Belgique
(2) Ssmg, Bruxelles, Belgique

Context: Complex situations are increasing in a GP Practice. But the application of clinical practice guidelines faces specific challenges in complex or multi-morbid situa-tions.

Methods: In these cases, the proposal is to shift the focus from disease-oriented care to patient's goal-oriented care (GOC), in which disease management becomes a means of sup-porting the achievement of the person's life goals. The GOC approach ("Goal Oriented Care") offers a method and tools for implementing this approach. Different primary care practices experimented the approach, giving lessons learned to go further in the application of the approach in general practice.

Originality: GOC invites to a paradigma shift, from a problem-focused practice to a goal-oriented interdisciplinair plan and action. It propose to take patient's life goals as a common direction for all the professionnals, and to make decision in dialog between patien

Lessons learned and future implication: This approach implies a series of conditions for implementation. The GOC involves listening skills, reflexivity, taking into account the context of the patient, with healthcare professionals translating the patient's personal goals into realistic professi

Discussion: GOC gives an opportunity for better involving the patient in the decisions about their healthcare. Otherwise, professionals have to pay attention on some risks of this shift in a cultural context of over-responsabilizing persons in taking care of their health. This can happen in a balance between repescting the preferences of the patients, and giving the right to vulnerability.

Conclusion: Goal oriented care is an approach to prioritize the care by following patient's life goals and prorities. Professionnals are trying it with satisfaction.

ID 1348- Physical Activity on Prescription for Alzheimer's Disease: A Delphi Consensus Study to Define Frequency, Intensity, Time, and Type of Exercise

Dragos Paul HAGIU [(1)] , Safa HADJ GACEM [(2)], Céline BESNIER [(3)]

(1) Département Médecine Générale,faculté De Médecine Jacques Lisfranc De Saint Etienne,université Jean-Monnet, Saint-Etienne, Saint-Etienne, France
(2) Département Médecine Générale,faculté De Médecine Paris-Saclay, Paris, France
(3) Maison Sport Santé De Savigny Sur Orge, Savigny Sur Orge, France

Context: Physical activity on prescription (PAP) is recognized as an effective preventive and therapeutic intervention for numerous chronic conditions. Despite these proven benefits, PAP remains under-prescribed in primary care. Existing guidance from the French National Authority for Health (HAS) offers general recommendations, but no consensus-validated prescription model currently exists to support clinicians in structuring PAP prescriptions.

Objectives: To develop and validate a consensus-based model for PAP prescription, including

frequency, intensity, time, and type of activity, designed for integration into a clinical decision aid for general practioners.

Methods: A preliminary decision tree was constructed based on a systematic literature review and recommendations from scientific bodies, including the HAS. Experts were recruited by inviting members of a scientific geriatric organization and through snowball sampling. Experts (physicians, physiotherapists, physical trainers) were consulted through iterative Delphi rounds using online questionnaires to validate the prescription model. Consensus for each item was defined as a median agreement score ≥7 on a 9-point Likert scale and ≥70% of responses within the [7–9] range. Items not meeting consensus thresholds were resubmitted in subsequent rounds until consensus was achieved.

Results: Three Delphi rounds were conducted. Most items reached consensus in the first round. Experts validated specific PAP modalities for patients with mild neurocognitive disorders, including: light-intensity endurance training 3 days per week for 30–60 minutes; muscle strengthening more than 2 days per week; flexibility exercises at least twice per week; and both static and dynamic balance exercises at least twice per week. Conversely, experts agreed that PAP is not adapted for advanced neurocognitive disorders; in these cases, physiotherapy was recommended instead, depending on mobility and functional autonomy.

Discussion: This study provides the first consensus-based PAP prescription model for patients with Alzheimer's disease and represents a step toward integrating structured PAP recommendations into a decision aid for primary care physicians. Limitations include a small, non-representative expert panel and the need to evaluate the model's usability and impact in real-world primary care.

Conclusion: We established a multidisciplinary consensus model for PAP prescription in Alzheimer's disease. This model will serve as the foundation for a clinical decision aid intended to further improve PAP utilization in primary care settings.

ID 953- Physical exercise and glycemic control in type 2 diabetes: an integrative review in primary care

Julia PANZAN, Gabriela ROGICK, Naila OLIVEIRA, Marcio MELO, Andre FREITAS, Brenno CAMPOS

Faculdade São Leopoldo Mandic Araras, Araras, Brésil

Context: Type 2 diabetes mellitus (T2DM) represents a substantial global health challenge, with primary care serving as the cornerstone for long-term disease management. Whilst physical exercise is widely acknowledged as a fundamental therapeutic component, its systematic implementation within primary care remains suboptimal. This integrative review synthesizes contemporary evidence examining the effectiveness of structured exercise interventions on glycemic outcomes in adults with T2DM managed in primary healthcare settings.

Objectives: To evaluate the impact of structured physical exercise interventions delivered within primary care on glycated hemoglobin (HbA1c) and fasting plasma glucose levels in adults with T2DM.

Methods: This PRISMA-compliant integrative review searched PubMed/MEDLINE using five controlled MeSH descriptors: Diabetes Mellitus Type 2, Exercise, Primary Health Care (including Family Practice and Community Health Services), Glycated Hemoglobin, and Blood Glucose. Eligible studies comprised primary research (randomized controlled trials, quasi-experimental designs, cohort studies, and analytical cross-sectional studies) published between 2015 and 2025 in English, Portuguese, or Spanish. Two independent reviewers conducted title/abstract screening and full-text assessment, with discrepancies resolved through consensus. Quality appraisal was performed using appropriate validated tools according to study design.

Results: From 42 identified records, 24 studies met eligibility criteria following systematic screening. Exercise interventions consistently demonstrated clinically significant improvements in glycemic parameters. Aerobic training, predominantly walking programmes at moderate intensity (3–5 sessions weekly), yielded HbA1c reductions of 0.3–1.8%, accompanied by significant decreases in fasting glucose.

Discussion: Resistance training produced comparable benefits, particularly when supervised and progressively intensified. Combined training protocols achieved the greatest HbA1c reductions. Primary care-integrated strategies (nurse-led counselling, community-based groups, mobile applications, and structured lifestyle programmes) proved feasible with high adherence rates. Digital health interventions enhanced self-management and sustained glycemic improvements. Notably, even modest activity increments, such as step-count targets, yielded meaningful metabolic benefits.

Conclusion: Structured exercise interventions implemented within primary care effectively improve glycemic control in adults with T2DM. Evidence supports aerobic, resistance, and combined modalities, with community-based and digitally-supported approaches demonstrating particular promise for sustainability and scalability. Integrating exercise prescription as standard primary care practice may substantially enhance metabolic outcomes and long-term diabetes management.

ID 433- GRAPPE: A participatory approach to promote physical activity in primary care

Jan BARAN, Lucile FAUQUETTE, Cindy BACQUAERT, Eiya AYED

Dmg Lille, Lille, France

Context: The GRAPPE (Groupe de Recherche en Activité Physique en soins PrEmiers) emerged in 2024 in a university-based primary care centre (MSPU) in northern France, in response to two converging needs: the sharp increase in thesis supervision demands following the national reform of postgraduate training, and the lack of primary care research on physical activity (PA). The simultaneous arrival of two master's students in Adapted Physical Activity (APA) catalysed collaboration between health and sport sciences, creating fertile ground for an interprofessional learning and research environment.

Methods: The initiative was designed to support interns in their thesis projects, pool supervisory expertise, and progressively build research culture within the care team. Monthly workshops, alternating with individual mentoring, guide students through question formulation, methodological choices, ethics and regulation, fieldwork, and dissemination. A shared digital workspace consolidates tools, protocols, and meeting summaries. The interprofessional group comprises 50 members, including medical, pharmaceutical, APA, nursing, sport science and administrative professionals, as well as a patient partner. To date, 18 students have developed projects. Strengths include flexibility of entry, strong local anchoring, and diverse expertise; limitations include heterogeneous student timelines and reliance on voluntary involvement.

Originality: Its originality lies in the integration of students from the fields of sport and health into a primary care research group composed not only of healthcare professionals, but also of professionals from sport and social sectors, as well as patient partners.

Lessons learned and future implication: Key learnings include the value of collective supervision, the importance of shared tools, and the need for explicit governance to sustain engagement. This project led to the submission of an application for Sport-Health Centre accreditation.

Discussion: While France hosts interprofessional initiatives such as the service sanitaire, few focus explicitly on producing primary care knowledge. Internationally, GRAPPE aligns with learner-centred research networks such as TUTOR-PHC, ARCs, or PBRNs, but distinguishes itself by a local scale bridging MSPU and CPTS, and by its single thematic entry point—physical activity—as a unifying, transdisciplinary domain.

Conclusion: GRAPPE demonstrates that a locally rooted, interprofessional and thematic approach can enhance research capacity in primary care. Its adaptability and collaborative governance offer promising avenues for sustainability and potential replication.

ID 376- Physical Activity Promotion in Patients With Motor Disabilities: The Role of General Practitioners.

Jérémy MARTINEAU [(1)] , Damien RAT [(2)]

(1) Université Rennes 2, Rennes, France
(2) Chu Pontchaillou Rennes, Rennes, France

Context: Physical activity provides numerous health benefits for people with disabilities, yet their participation rates remain significantly lower than those of the general population.

Objectives: This study aimed to explore how individuals with motor disabilities perceive the role of general practitioners in promoting physical activity.

Methods: This qualitative study was based on semi-structured individual interviews conducted between December 2023 and June 2024 with adults living with permanent motor disabilities. Participants were recruited either from specialized rehabilitation centers or through regional sports committees for individuals with disabilities. Data were analysed using an inductive thematic approach.

Results: Twenty-five participants aged 21 to 78 years, presenting diverse motor impairments, were interviewed. They reported multiple barriers to physical activity (e.g., accessibility issues, lack of information...) as well as substantial perceived benefits. Several avenues for action by general practitioners were identified: screening for physically inactive patients, communication and awareness-raising, referral to appropriate structures, individualized follow-up, and peer connection with individuals already engaged in parasport.

Discussion: General practitioners are central in promoting physical activity among individuals with motor disabilities. The development of initiatives such as Sport-Health pathways and parasport networks offers opportunities to enhance access and participation. Structural, social, and educational barriers limit opportunities despite well-documented benefits. Improving the visibility of adapted physical activity networks and coordination among healthcare providers are key levers. This study provides actionable insights to guide future Sport-Health initiatives in primary care and highlights the need to strengthen prevention strategies for this underserved population, supported by a summary poster compiling useful resources for healthcare professionals and patients.

Conclusion: General practitioners play a pivotal role in supporting individuals with motor disabilities to engage in physical activity, by providing guidance, ensuring safety, and facilitating access to adapted resources.

ID 195- An IDEAL setting for research in general practice

Eric MENER, Sarah-Lou MAMOUNE, Benjamin BASTIAN

Université De Rennes, Rennes, France

Context: Insomnia is a major public health problem in France. Outpatient treatment focuses on improving sleep hygiene and non-pharmacological interventions (NPIs). Hypnotherapy is becoming increasingly popular in primary care. A growing number of publications attest to its effectiveness, but they suffer from poor methodological quality. How can the benefits of this brief therapy in the treatment of chronic insomnia in general practice be demonstrated?

Methods: In 2009, the IDEAL conceptual framework was proposed in The Lancet to evaluate an innovative surgical method and strengthen the methodological quality of clinical evaluations of complex therapies. Description of how our team has adopted this concept, illustrating each step of the process with the work carried out by our team. • "I" (Idea): describe the innovative technique through a case study. A publication described the innovative hypnotherapy method used. • "D" (Development): explore the importance of developing research in the field concerned with several qualitative and quantitative studies in general medicine. • "E" (Exploration): ensure feasibility through a retrospective descriptive study. • "A" (Assessment): evaluate the effectiveness of the hypnosis method with an ongoing randomized

controlled trial. • "L" (Long Term Study): conduct long-term follow-up.

Originality: The IDEAL conceptual framework is used to evaluate other NPIs (physical therapy, acupuncture), but this is a novelty in hypnosis research. Its originality lies in its outpatient setting, which requires adaptations compared to hospital-based studies. It co

Lessons learned and future implication: After several project funding refusals due to a lack of structure and a re-evaluation of our previous approach, we adopted the IDEAL approach to conduct a randomized controlled trial. This is the price that research teams must pay to be able to carry out

Discussion: This innovative approach allows a comprehensive and rigorous evaluation of a complex therapy, hypnotherapy, for insomnia, common problem in general practice. Research teams in our discipline would benefit from adopting this IDEAL framework, which is a lengthy but rigorous process.

Conclusion: IDEAL approach opens up ambitious research prospects for general practice and could contribute to the growth of research in our discipline to improve general medical care.

ID 1023- Promoting Research Engagement with Underserved Communities in Primary Care: Learning from the REACH Project

Serge ENGAMBA [(1)] , Julian ADAMS [(1)], Iain BOAG [(2)]

(1) Norwich North Primary Care Network, Norwich, Royaume-Uni
(2) St Martins Trust, Norwich, Royaume-Uni

Context: People experiencing homelessness, addiction and severe mental illness face extreme health inequalities yet remain persistently underrepresented in health research. A primary care team working with a residential service for individuals with dual diagnosis noted that residents had minimal understanding of what research is or how to engage with it. The REACH initiative (Research Engagement and Awareness for Communities in High-Need Settings) sought to explore how research awareness could be safely and meaningfully introduced within this high-exclusion environment.

Methods: Using an iterative, co-produced approach, residents, support staff andclinicians participated in short, opportunisticconversations tailored to fluctuating mental state, concentration and daily stability. Residents completed a three-question set exploring prior research experience, motivators and concerns. Three-week follow-up conversations explored recall. Staff assessed materials separately andcontributed to a simplified, visual resource suited to the residential environment. Strengths included reliance on trustedrelationships, flexible timing and visual communication. Limitations included variable attendance, cognitivefluctuation and extremely lowretention of writtencontent.

Originality: There is limited evidence on how to build research awareness within residential services for people with multiple exclusion, co-occurring mental illness and substance use. REACH differs from traditional research-engagement approaches by embedding conversa

Lessons learned and future implication: Trust was the key engagement mechanism; residents preferred conversations initiated by familiar staff. • Motivators were concrete: small payments, knowing the person asking and clear, simple information. • Concerns centred on ethics, data use and

Discussion: Meaningful research engagement in high-need settings requires relational continuity, trauma-aware communication and adaptation to fluctuating capacity. This case offers transferable learning for European primary care teams addressing research inequity.

Conclusion: REACHdemonstrates that research awareness can be fostered within highly excluded populations when approached relationally, sensitively and collaboratively, providing a practical model for improving research inclusion.

Corresponding author: Serge Engamba, s.engamba@exeter.ac.uk

ID 2071- Advancing Equity Through Patient Engagement in Research: Scaling Up an Integrated Care Program

Mathieu COOK [1] , Alexandra LEMAY-COMPAGNAT [2], Mireille LAMBERT [1], Maud-Christine CHOUINARD [3], Magaly BRODEUR [2], Marie-Dominique POIRIER [2], Daniel BOLEIRA GUIMARAES [2], Sabrina WONG [4], Catherine HUDON [2], Vivian RAMSDEN [5]

(1) Université De Sherbrooke, Saguenay, Canada
(2) Université De Sherbrooke, Sherbrooke, Canada
(3) Université De Montréal, Montréal, Canada
(4) University Of British Colombia, Vancouver, Canada
(5) University Of Saskatchewan, Saskatoon, Canada

Context: Scaling up integrated care programs for individuals with complex needs requires adaptability across contexts and a strong commitment to engaging diverse communities. Meaningful involvement of patient partners from different backgrounds and identities is crucial for promoting health equity and expanding opportunities to actively engage in research. However, strategies to effectively engage these partners require more detailed description.

Objectives: To provide a comprehensive description of the engagement strategies for 2SLGBTQIA+, Indigenous, and migrant patients partners during the scale-up and evaluation of an integrated care program.

Methods: The study uses a participatory approach embedded within a larger mixed-method, multiple-case design. From fall 2024 to Spring 2026, monthly meetings allowed patient partners to share care experiences, provide program feedback, and contribute to research decisions. A senior patient partner offered specific mentoring and teachings. The team documented engagement in a logbook, wrote reports after each meeting summarizing discussions, and gathered ongoing feedback throughout. Final insights were reviewed and refined by patient partners.

Results: The committee demonstrated relative stability in its composition, although it occasionally struggled to maintain engagement. Cultural safety measures were deemed necessary, such as smudging with sage during meetings. Pluralism and equity were promoted by ensuring balanced representation of communities within the committee. Members received training sessions on the integrated care program and patient engagement in research. They also co-drafted the Terms of Reference and advised the team on adaptations to intervention tools and a semi-structured interview guide. Some patient partners shared experiences within a community of practice for case managers.

Discussion: Involving patient partners with diverse identities in the same committee is feasible and beneficial for enriching both the content and conduct of research but requires careful implementation and attention to fostering interpersonal bonds.

Conclusion: The engagement process offers actionable insights for research teams aiming to include patient partners from diverse communities, highlighting strategies to promote equity and meaningful participation.

Corresponding author: Mathieu Cook, mathieu.cook@usherbrooke.ca

ID 2005- When saying is not enough ;adapting communication to improve health literacy in patients with chronic diseases

Duverne PEGGY

Université Picardie, Courbevoie, France

Context: People living with chronic diseases often experience cognitive, social, and emotional vulnerabilities that limit their understanding of health information. These difficulties negatively affect health literacy, treatment adherence, and the quality of care pathways.

Objectives: This study aimed to analyse the influence of health literacy on the management of chronic diseases by comparing patients' and healthcare professionals' perceptions. It also explored how healthcare professionals adapt their communication, the barriers to understanding, and their impact on health literacy and care pathways.

Methods: A mixed-methods study with a predominantly qualitative design was conducted. The quantitative phase consisted of an exploratory survey carried out over eight weeks among patients with chronic diseases (n = 107) and healthcare professionals (n = 111). Descriptive analyses focused on clarity of language, educational materials, and time devoted to explanations. The qualitative phase followed a phenomenological approach, with semi-structured interviews conducted with 15 patients, including two expert patients, and 18 healthcare professionals. Data were analysed using interpretative phenomenological analysis.

Results: A discrepancy was identified between patients' perceived understanding and the information that healthcare professionals believed they provided: 53% of patients considered the information clear, compared with 69% of healthcare professionals. Regarding educational materials, 31% of patients expressed a need for them, but only 27% reported having received them, whereas 65% of healthcare professionals stated that they provide such materials. Qualitative findings highlighted five main themes: time constraints, patient vulnerabilities, educational materials, the healthcare professional–patient relationship, and the organisation of care pathways.

Discussion: The results confirm that health literacy plays a key role in patient autonomy and treatment adherence. The intention to inform alone is insufficient. Plain language, reformulation, adequate time for explanation, and appropriate educational materials are essential.

Conclusion: Integrating health literacy into clinical practice is therefore necessary to improve understanding, strengthen patient autonomy, and secure care pathways, particularly through adapted and easy-to-understand educational resources.

ID 1923- Between Emancipation and the Anticipation of Conjugal Risk: Understanding Solo ART Pathways as Women's Practices of Reproductive Autonomy

Le Bris ANNE [(1)], Lina AMZILE [(2)] , Célia RAVEL [(3)]

(1) Eso Rennes, Rennes, France
(2) Rennes, Rennes, France
(3) Irest Rennes, Rennes, France

Context: The 2021 Bioethics Law profoundly transformed the legal framework governing medically assisted reproduction (MAR) in France by opening access to assisted reproductive technologies (ART) to single women and female same-sex couples. Healthcare professionals are thus confronted with new family configurations that challenge their professional frames of reference, their support practices, and their representations of "ideal" parenthood.

Objectives: The aim is, on the one hand, to gain a better understanding of the social, emotional, and material motivations that lead to this reproductive choice in a context marked by persistent conjugal inequalities and by a growing questioning of the heterosexual couple as a prerequisite for parenthood, and, on the other hand, to reflect on the medical support provided for these specific reproductive trajectories.

Methods: This research is based on a multi-sited qualitative study and draws on three types of empirical material: the analysis of autobiographical narratives from around ten books written by women who have undergone solo ART; the study of exchanges and discussions on social media, which provide access to contemporary forms of collective storytelling; and in-depth interviews conducted both with women engaged in a solo ART process and with healthcare professionals involved in their care.

Results: This methodological combination makes it possible to jointly capture the situated experiences of patients and the professional, ethical, and normative logics that structure medical support. Solo ART trajectories are marked by a wide diversity of social situations, but also by recurring motivations related to the search for emotional security, material stability, and reproductive autonomy.

Discussion: Preliminary analyses suggest the existence of tensions between women's expectations and medical support practices, particularly when implicit forms of judgment, conjugal normalization, or the infantilization of patients persist.

Conclusion: By jointly analyzing women's narratives, online exchanges, and professional practices, this research contributes to a better understanding of the social and medical issues surrounding solo ART in post–2021 Bioethics Law France.

ID 1753- Barriers and facilitators to attending and accessing general practice consultations by patients with very low health literacy

Clarisse BITTAR, Leon BANH, Jean-Denis HOONAKKER

Upec, Creteil, France

Context: Low literacy level has a negative impact on health and is a lever to promote individual health and autonomy. Patients with very low literacy level have difficulty making appointments (appts) and attending general practice (GP) consults.

Objectives: Identify and understand the barriers and levers to making and attending GP appts among patients with very low literacy level in order to facilitate and improve their access to healthcare.

Methods: Qualitative study of 13 semi-structured individual interviews, from June 2024 to April 2025, recruited by general practitioners (GPs) via Single-Item Literacy Screener (SILS). Analysis inspired by grounded theory and data triangulation.

Results: Patients struggled with communicating, managing schedules, social and administrative procedures, digital tools, and finding their way around. They could call, go to the medical offices to make an appt but they almost never did it online. Overwhelmed, they were dependent on caregivers in particular. Some were resilient and sought to become autonomous in order to communicate : personalized directories, voice messages, spellcheckers ; to memorize better : memory aid, visual identification, gesture repetitions. They found the reminder messages useful and suggested using a file number to make it easier to make appts. The quality of the physician-patient relationship promoted communication and patient engagement. The GPs facilitated access to care by directly making appts, by directing patients to secretariats, colleagues, and healthcare facilities.

Discussion: The study's limitations include : the SILS was modified but not tested or validated before use ; patients had difficulty understanding the purpose of the interview ; interviews were conducted only with patients who had managed to book appts ; and recruitment was carried out by GPs who were more familiar with the topic. Strengths include triangulation of analyses, logbook. Missed appts are a marker of vulnerability and a warning sign for healthcare professionals. Digital literacy, the quality of the physician-patient relationship, and the role of caregivers all influence patient attendance.

Conclusion: Recognizing these difficulties is a challenge in promoting the gradual empowerment of patients.

Corresponding author: Clarisse Bittar, clarisse.bittar@gmail.com

ID 454- Developing public health competencies in primary care through a new master's specialization

Violaine BRUNELLI-MAUFFREY

University Of Lorraine, Nancy, France

Context: A new paradigm is emerging between primary care and public health, shifting from an individual-focused model to a more population- and community-oriented approach. Prevention must become a shared mission among professionals, supported by clarified roles and appropriate training. In this perspective, EUROPREV recently highlighted key priorities: evidence-based interventions, structural integration of prevention, prioritization of high-risk patients, and proportionate universalism. However, many primary care teams still lack methodological and organizational skills to structure territorial prevention actions. The development of coordinated care—within multidisciplinary group practices, primary care teams, and territorial professional health communities—strengthens the

need for specific public health competencies. Preliminary studies identified two major barriers: the absence of dedicated training tailored to primary care, and insufficient resources to design structured prevention projects.

Methods: Between 2018 and 2024, a progressive process led to the development of a dedicated training pathway. A first study confirmed the need for such training. The DU CSP2 (University Diploma in Coordination of Public Health Actions in Primary Care) was created to introduce primary care teams to project methodology and territorial public health. After three student cohorts and significant regional impact, the need for further professionalization became evident. This resulted in the creation of the M2 PPS – AOSP (Master's in Prevention and Health Promotion – Specialization in Actions and Organisations in Primary Care). This program deepens competencies in primary-care health policy, interprofessional research, and territorial public health communication. It combines e-learning, on-site sessions, and a practicum focused on a territorial prevention intervention.

Originality: This is the first graduate program in France specifically dedicated to designing and implementing public health actions within primary care.

Lessons learned and future implication: Participants report significant improvements in coordination, territorial diagnosis, evaluation, and communication. The program supports new roles, such as primary care public health project officers, and strengthens population-centred primary care.

Discussion: This experience shows that dedicated training can strengthen territorial public health capacity and support interprofessional collaboration.

Conclusion: The M2 PPS – AOSP provides an innovative and timely response to transformations in primary care by integrating prevention, project methodology, and population-health responsibility into daily practice.

Corresponding author: Violaine Brunelli-Mauffrey, violaine.mauffrey@univ-lorraine.fr

ID 298- Patient Experience of Health Problems in General Practice Consultations: A Qualitative Study using the Own-Point-of-View Perspective

Louis-Baptiste JAUNAY

Paris Cité, Paris, France

Context: General practice consultations bring together the GP and patient around the latter's health issues. Research has focused on the mental problem-solving activity of the GP, referred to as clinical reasoning. However, decision-making in consultations is increasingly conceptualized not only as the outcome of the GP's reasoning but also of the patient's problematization activity.

Objectives: The purpose of this work is to explore the experience a patient has and makes of their health problems during a general practice consultation.

Methods: Data were collected through video-stimulated recall interviews with patients after their consultations. Consultations were filmed from the patient's perspective using wearable camera glasses. Each interview comprised two parts: (a) an explicitation interview exploring the patient's experience and reasoning before the consultation, and (b) a video-based stimulated recall to analyze their experience during the consultation. John Dewey's theory of inquiry provided our analytical framework.

Results: Twelve in-depth interviews were conducted. Our analysis allows us to describe the patient's approach to the consultation according to three themes: - the experience prior to the consultation - the decisions to share information with the GP - the reception of the GP's messages. When identifying health problems, patients develop and examine hypotheses related to the possibilities for action and resolution that they offer. Among these possibilities is making an appointment with a GP. During the consultation, patients decide to share certain information with the GP based on their perception of the latter, and receive messages based on how well they fit with their inquiry.

Discussion: The GP's activity appears to be decisive in terms of the messages they convey to the patient

and the positions that these messages imply for the patient's inquiry. One limitation is that we explored patients' experiences after a single consultation. Future studies could explore the experience of follow-up care.

Conclusion: This work has made it possible to analyze the patient's experience during consultations. It provides insights into understanding the transformative potential of consultations on patient activity and the concepts of adherence or, conversely, non-adherence. It thus opens up new perspectives for GP education.

ID 2176- Evaluation of the association between vitamin D prescription in general practice and the occurrence of bone fractures in children aged 3 to 7 years

Arthur VRIGNAUD [1] , Célia BIGOT [2], Constance CLERC [2], Anastasia LEMENN [2], Jessica GUELFF [1]

(1) Msp Conlie, Conlie, France
(2) Faculté De Médecine, Angers, France

Context: Bone fractures are common events in children's life and have significant consequences on their biopsychosocial development. The link between vitamin D deficiency and bone fragility is well established in adults but less supported in pediatrics.

Objectives: Our study evaluated the association between vitamin D prescription in general practice and occurrence of bone fractures in the pediatric population, along with a descriptive analysis of vitamin D prescription by physicians and fractures occurrences within our sample.

Methods: It is a monocentric, observational and analytical and retrospective cohort study in children aged 3 to 17 years in the medical center in Sarthe (France). We evaluated the vitamin D prescription, adherence rate to uniform guidelines from 2012 to 2021, and fracture events.

Results: In this study, no significant difference was found between the fracture occurrence and the adherence to vitamin D prescription recommendations (p=0.098). Among 603 patients, the average adherence rate to vitamin D prescription guidelines was 19.2%. 83.4% (n=503) of patients had an adherence rate below 50%. 55.8% (n = 335) having an adherence rate of 0%. Only 5% (n = 31) of patients achieved the maximum adherence rate.

Discussion: This is the first study to evaluate the rate of vitamin D prescription using the total prescribed dose calculation method in general practice. The results did not demonstrate an association between vitamin D supplementation rate and occurrence of fracture events in children.

Conclusion: Further studies including data from nearby emergency departments could be useful in confirming these results.

ID 1989- Assessment of knowledge about the psychomotor development of children aged 0 to 2 years among parents who consult healthcare facilities in the île-de-france region

Cecilia SALDANHA GOMES, Justine HIERSO

Sorbonne Universite, Paris, France

Context: Psychomotor development is a dynamic process, with significant interindividual variability. Neurodevelopmental disorders must be identified early during child follow-up consultations. Parents' knowledge of young children's psychomotor development is essential to make them aware partners. Several international studies report that parents' knowledge of psychomotor development is poor, but to our knowledge, no study has been conducted in the Île-de-France region.

Objectives: The main objective of our study is to assess the knowledge of parents in Île-de-France on the psychomotor development of children aged 0 to 2 years.

Methods: This is a multicenter study conducted using a self-administered questionnaire completed by parents of children aged 0 to 5 years. This questionnaire enabled us to obtain a knowledge score out of 15, based on 15 questions about child development from 0 to 2 years of age, in the four areas of development. This score was then dichotomized according to the median level of knowledge into two groups (good knowledge and poor knowledge). We then studied the association between parents' level of knowledge about the psychomotor development of children aged 0 to 2 years and their sociodemographic characteristics, using bivariate analyses followed by multivariate analyses using logistic regression and linear regression. The data were processed using Excel and R++, with a significance threshold set at 0.05.

Results: We included 466 parents with at least one child under the age of 5 who were consulting at 23 healthcare facilities in the Île-de-France region in our study. The average knowledge score for parents in our study was 5.7/15 points (+/- 2.1). We observed a significant positive association between knowledge level and being a mother, as well as having a higher education.

Discussion: The level of knowledge among parents about psychomotor development in young children in our study is low, which is consistent with the literature. Doctors must implement a proactive approach for all parents in general. At the same time, doctors must be very attentive to the child's neurodevelopment during follow-up consultations, as parents cannot be considered whistleblowers.

Conclusion: Parents' knowledge of young children's psychomotor development is low, but public health policies that promote validated content could help improve this knowledge.

ID 1781- Seeking consent for clinical examination in children aged 2 to 6 years in general practice consultations

Alexia MESSON, Céline LÉRAN

Université Clermont Auvergne, Clermont-Ferrand, France

Context: In France, 160,000 children are victims of sexual abuse each year, often at a very young age. Prevention requires education on consent, which also applies to healthcare interactions. Neuroscience shows that children as young as two can understand and express a form of consent.

Objectives: The purpose of this study was to explore general practitioners' practices and perceptions regarding consent for clinical examinations in children aged 2 to 6 years.

Methods: Using a qualitative approach grounded in thematic analysis, we conducted semi-structured interviews with general practitioners in the Puy-de-Dôme region. Topics included current practices, definitions of consent, and parental involvement. Data were analyzed through open, axial, and integrative coding, coupled with investigator triangulation to develop an explanatory model, which is illustrated in a diagram.

Results: Physicians' experiences strongly influenced their approach to consent. Barriers included limited awareness, uncertainty about procedures, discomfort when a child refused, and the inherent power imbalance between adults and children. Effective strategies involved building trust through parental reassurance, creating a supportive environment, fostering positive interactions, and respecting the child's privacy and choices. Training and reflective practice emerged as key levers for improvement.

Discussion: The investigators' limited experience in qualitative research may represent a limitation. This was mitigated through extensive literature review and specific training at the Clermont-Ferrand Faculty of Medicine. Social desirability bias, possible due to the sensitive topic, was minimized by the investigator's lack of prior relationships with participants and by sufficiently long interviews encouraging openness. The confirmation bias was reduced by noting the investigators' preconceived notions before conducting the study and by performing an investigator triangulation. Reconsidering consent in clinical examinations of children is essential to strengthen ethical standards and protect children from harm. This requires

clarifying the concept of consent for young children and integrating practical approaches into routine consultations.

Conclusion: Multiple strategies exist to seek consent for clinical examinations in children aged 2 to 6 years, along with promising prospects for enhancing current practices.

ID 869- Implémentation d'un programme d'éducation thérapeutique pour les troubles alimentaires pédiatriques en soins primaires : une première expérience dans les Hauts de France.

Isabelle CHARDONNET, Jan BARAN

Mspu Corneille / Cpts Des 7 Villes, Wattrelos, France

Context: Paediatric feeding disorders (PFD) are common but often under-recognised in primary care. Families frequently face long diagnostic delays and fragmented management. Therapeutic patient education (TPE) programmes exist in hospital settings but remain rare in community care.

Methods: The pilot programme was launched in February 2025 within the Maison de Santé Universitaire Corneille (Hauts-de-France). It was developed by a primary care team in partnership with the regional CPTS, which will provide ongoing financial support to extend the initiative. This programme consists of five 2-hour workshops involving one child (aged 3–8) and at least one parent per session. Each group includes six children and fourteen parents, supervised by three health professionals—always including a speech therapist—trained in TPE and Nonviolent Communication. Sessions cover eating mechanisms, posture, nutrition, sensory exploration, and emotional regulation.

Originality: This programme is original in bringing a structured, multidisciplinary TPE approach for paediatric feeding disorders into primary care, whereas existing models are almost exclusively hospital-based. It innovatively mobilises a local healthcare network (CP

Lessons learned and future implication: The first cycle involved six children and their families. Early feedback indicates high engagement, improved parental confidence, and observed progress in children's mealtime comfort. Twenty-four additional families are already registered and awaiting the

Discussion: The first TPE group for children aged 4–6 enabled a comprehensive reassessment of all workshops offered. A revised version of the programme will be delivered in March 2026 to children aged 6–8 and their parents. A psychologist will also be integrated into the project.

Conclusion: This first TPE programme implemented in primary care demonstrates feasibility, strong acceptability, and interprofessional collaboration. It offers a promising model for community-based management of complex paediatric feeding issues.

ID 273- Preventing screen exposure in children aged 3 to 6 : creation of a children's album

Emmanuelle MORIVAL [(1)] , Hélène VAILLANT-ROUSSEL [(2)], Mickaël BIGEAULT [(3)]

(1) Department Of General Practice, Ufr Medicine And Paramedical Professions, Université Clermont Auvergne, Clermont-Ferrand, France
(2) Department Of General Practice, Ur Acceppt, Ufr Medicine And Paramedical Professions, Université Clermont Auvergne, Clermont-Ferrand, France
(3) Department Of General Practice, Clermont Auvergne Inp, Ufr Medicine And Paramedical Professions, Université Clermont Auvergne, Clermont-Ferrand, France

Context: Early screen exposure in children raises major public health concerns. However, only 13.5% of parents follow the available recommendations. Moreover, activities such as reading, which are beneficial to a child's development, are sometimes neglected in favor of screen time.

Objectives: To create a children's book aimed at kids aged 3 to 6, with the goal of preventing inappropriate screen use. This book is designed to provide both children and their caregivers an interactive reading experience that encourages discussion about screens and their potentials risks.

Methods: A multidisciplinary working group was formed to define and validate the written content. Each member answered four questions to help develop the book's content. The design of the book was based on the principles of dialogic interactive reading and on Sabine Duflo's four-step method.

Results: The working group was composed of eleven members, including health professionals, early childhood specialists, communication experts, and parents. Seven of the eleven members met to review the manuscript and made the necessary modifications. The book features five anthropomorphic characters facing problematic situations involving screens, followed by a sixth character who provides recommendations. The proposed interactions were inspired by a questionnaire designed to identity inappropriate screen use. Two parenting guides are also included in the book.

Discussion: This prevention album was created for children and their family, and to promote reading.The book could serve as a resource during consultations, helping to meet parents' expectations by addressing the topic of screen use more regularly and comprehensively. A further study could evaluate the quality of the album to determine the interest in creating a collection book focused on prevention.

Conclusion: Choosing the children's book as a means of prevention allowed it to serve as mediation tool between children and their surroundings. This project represents the first prevention book on screen use reviewed by a panel of experts and designed by a healthcare professional.

ID 260- Parental Role in the Care Pathway of Children with Autism Spectrum Disorder: A Qualitative Study of Parental Representations

Mathilde MINET, Mathilde DUCROS

Dumg Montpellier, 48000, Mende, France

Context: Autism Spectrum Disorders (ASD) are common and exhibit highly heterogeneous profiles, making the support and care of affected children complex. Once heavily stigmatized, parents are now recognized as key stakeholders in the care pathway.

Objectives: Exploring Parents' Perceptions of Their Role in the Care Pathway of their children with ASD

Methods: A phenomenological qualitative study conducted with nine parents of children with Autism Spectrum Disorder (ASD). Data were collected through individual semi-structured interviews using an interview guide (33 min - 144 min).

Results: Parents play a central role in their child's care pathway. They contribute to the early identification of warning signs and describe the diagnostic process as lengthy and complex. Following diagnosis, they actively participate in their child's care, implement strategies to promote development and autonomy, and collaborate closely with healthcare professionals. This involvement leads to the emergence of "parent-experts," who share their knowledge with both their social network and care teams. In addition, parents advocate for their child's rights and engage in efforts to promote a more inclusive society and school environment. While parents demonstrate strong engagement and adaptability, they also highlight significant unmet needs. These include support, care coordination, professional training, access to appropriate resources, and broader societal awareness.

Discussion: Addressing these gaps is essential to optimize care pathways and foster true inclusion for children with Autism Spectrum Disorder. Parents's involvement enhances early detection and supports developmental progress, yet significant gaps persist in coordination, resources, and professional training. Recognizing and leveraging parental expertise could improve care continuity and promote inclusive practices.

Conclusion: This study highlights the importance of recognizing and supporting parental expertise to sustainably improve the care pathway and the quality of life of children with Autism Spectrum Disorder (ASD) and their families.

Corresponding author: Mathilde Ducros, mathilde.ducros01@etu.umontpellier.fr

ID 211- Practices of professionals in a care network regarding the inclusion of family members in managing childhood overweight and obesity

Laura KATZ, Frédéric ZORZI, Camille CANAPLE

Ufr Médecine Lyon Est, Lyon, France

Context: Obesity is a chronic disease with multifactorial determinants requiring a multidisciplinary approach addressing multiple aspects of the child's and family's life. Integrating family members is recognized as a key factor for effective care, as is the role of health professionals in facilitating this involvement. Pediatric obesity care networks have emerged in many countries, including France, where they support families. While some studies have explored families' expectations within such networks, few have examined how professionals involve families in care, and none were found concerning this specific network.

Objectives: To explore how professionals working within a care network integrate a family-centered approach in the management of children and adolescents with overweight or obesity.

Methods: A qualitative research design was used. Semi-structured face-to-face interviews were conducted with professionals affiliated with the care network. Recruitment was carried out via an email invitation sent to all members, with inclusion based on voluntary response and availability for interview.

Results: Twenty interviews were conducted between March and November 2024 (9 physicians, 7 dietitians, 3 psychologists, and 1 nurse), with an average duration of 44 minutes. A wide range of approaches emerged, from child-centered to systemic models. This diversity appeared in how participants defined care objectives, organized consultations, involved family members, and collected verbal and nonverbal information. Participants expressed awareness of family-related barriers influencing care and reported adapting their communication, professional stance, and advice accordingly. Several demonstrated reflexivity and a willingness to further develop their practices. An unexpected finding was a strong expressed need for teamwork among participants.

Discussion: Strengths included the originality of the topic, multidisciplinary sample, and methodological rigor. Limitations concerned partial triangulation of data analysis and the author's first qualitative research experience. Perspectives include promoting systemic training, collective care models, and interprofessional collaboration through local multidisciplinary teams.

Conclusion: This study highlights the diversity of professional practices in pediatric obesity care and the essential role of family inclusion and teamwork to improve care quality and outcomes.

ID 930- Prevalence of elevated blood lead levels in migrant children: a systematic review and meta-analysis

Kim BONELLO, Hugo FIGONI, Marie LAPILLONNE, Théo DUGUET, Sarah ROBERT

Sorbonne Université, Paris, France

Context: Elevated Blood Lead Levels (EBLL) is defined by a blood lead level above 5µg/dL, even though some consequences may appear below this threshold. EBLL is responsible for significant complications, especially for children. The prevalence of EBLL in children is less than 1% in most high-income countries. Some migrant children are more exposed, due to cumulative risk factors.

Objectives: The aim of this study is to estimate the prevalence of EBLL in migrant children in high-income countries.

Methods: A systematic review was conducted using PubMed, Embase, Web of sciences and CINAHL databases. Studies published since 2012 (new blood lead threshold), conducted in an OECD country and with prevalence of EBLL in children from a low- or middle-income country as their primary outcome were included. An independent double reading of titles abstracts then full texts was performed, with third-party advice in case of disagreement. A meta-analysis of prevalence rates was carried out.

Results: Of 288 studies screened, 12 were included. The meta-analysis showed a 24% [CI95 18-30%] prevalence of EBLL among migrant children. Age subgroup analysis showed a 29% [CI95 22-36%] prevalence of EBLL among children aged six or under. Young age and Asian countries of origin were factors associated with EBLL in this population.

Discussion: The study was conducted using rigorous methodology (PROSPERO registration, diverse databases, validation of the search equation by a methodologist) and reported according to PRISMA guidelines. Heterogeneity between articles can limit the interpretation of pooled prevalences. This bias was limited by using random-effect models.

Conclusion: The prevalence of EBLL in migrant children is much higher than in non-migrant children born in OECD countries. Considering the health consequences, it seems paramount to propose a systematic blood lead level measurement in this population and provide appropriate support.

Corresponding author: Kim Bonello, kim.bonello@sorbonne-universite.fr

ID 757- Approach to adolescents exposed to social media: a qualitative study among general practitioners

Marie GANDON

Faculty Of Medicine, University Of Rennes, Rennes, France

Context: The rise of social media (SM) affects adolescents from an early age, with 82% of 7–17-year-olds registered on at least one platform in 2024. Its impact on mental and physical health can vary depending on the type of use and the vulnerability of each adolescent.

Objectives: The aim of this study was to explore how general practitioners (GPs) perceive, address, and integrate the risks associated with adolescents' exposure to social media into their clinical practice.

Methods: A qualitative study was conducted using grounded theory. Nine individual semi-structured interviews were carried out with general practitioners in XXX from March 2024 to January 2025.

Results: A total of nine interviews were conducted, each lasting an average of 50 minutes. General practitioners perceived social media exposure as a potential risk to adolescents' mental health, with the main concern being the development of addiction. Their knowledge was primarily empirical, based on personal experience. They chose to engage in targeted screening of misuse but encountered difficulties communicating with adolescents. They considered prevention the responsibility of parents and schools and delegated management to mental health specialists. Issues related to societal modernization and the boundary between education and healthcare raised questions about their own legitimacy. The lack of scientific evidence and the low frequency of encountering such cases in practice led them to question the relevance of the issue. They expressed willingness to be more involved if all necessary stakeholders were engaged in appropriate care.

Discussion: GPs associated the risks of social media use in adolescents with a potential new behavioral addiction. This hypothesis is supported by many researchers, who compare it to video game addiction, recently recognized as a disorder. Faced with the lack of formal guidelines on the topic, GPs responded to this emerging issue using what Gabbay and Le May describe as "mindlines." Our findings were compared with adolescents'

perspectives on the issue to provide guidance for GPs.

Conclusion: GPs provide an instinctive and cautious response in their practice to what they perceive as a risk to adolescents' mental health. Their engagement appears to be evolving, dependent on the active involvement of other stakeholders and the provision of training.

Corresponding author: Marie Gandon, marie.gandon1@gmail.com

ID 488- Feelings and attitudes of childcare assistants towards "picky eaters": insights for general practitioners

Marianne CASTELNAU, Philippe CORNET

Sorbonne Université, Paris, France

Context: Around 25% to 50% of young children are considered "picky eaters", showing selective food intake or limited appetite. Anxious parents often turn to their general practitioner (GP) for guidance, yet GPs frequently feel uncertain about how to manage these consultations. Childcare assistants have daily experience of feeding children and may provide valuable insights for primary care practice.

Objectives: To explore the feelings, attitudes, and strategies of childcare assistants when caring for "picky eaters", and to identify lessons that could support GPs facing similar situations.

Methods: A qualitative study was conducted among childcare assistants working in municipal nurseries in XXXX, combining two complementary methods. First, a word association method, widely used in sociology and psychology, collected spontaneous words in response to the inductor "picky eaters". Second, in-depth, comprehensive interviews focused on real-life situations and were analysed using an interpretative phenomenological approach. Homogeneous purposive sampling was used. Data triangulation was applied to strengthen consistency and depth of interpretation.

Results: 32 childcare assistants participated in the study: 30 completed the word association method and 16 took part in the interviews. Participants reported a wide range of emotions, from anxiety and helplessness to joy and professional satisfaction when progress was observed. Their approach combines two key dimensions: understanding and resolving. Understanding relies on close observation of the child during meals and open dialogue with parents to identify physical, emotional, or environmental causes. Resolution involves creating a safe and trusting environment, showing patience, and respecting the child's pace without forcing food. Shared meals promote imitation and enjoyment. Collaboration with parents and the multidisciplinary nursery team is central to their approach.

Discussion: This study's strengths lie in the originality of its topic and the complementarity of its two qualitative methods. Combining our findings with the literature, we developed a guidebook to support GPs, bringing together clinical considerations, classification, practical advice for parents, and reliable additional resources.

Conclusion: Feeding difficulties in young children are complex and require a bio-psycho-social approach. Empathy, flexibility, and trust-building are essential in supporting children and parents. Strengthening dialogue between early childhood professionals and GPs could enhance confidence, knowledge, and quality of care in consultations about feeding difficulties.

ID 238- Impact of the French National Health Authority's Guideline on Appropriate Proton Pump Inhibitor Prescriptions in Infants with Gastroesophageal Reflux

Paloma LUQUE [(1)], Catherine BISQUAY [(1)], Valérie THIEUZARD [(2)], Pierre-Alain JACHIET [(1)], Laurence WATIER [(3)], Moussa LAANANI [(1)]

(1) Mission Data, Direction Générale, Haute Autorité De Santé, Saint Denis, France
(2) Service Des Bonnes Pratiques, Direction De L'amélioration De La Qualité Et De La Sécurité Des Soins, Haute Autorité De Santé, Saint Denis, France
(3) Anti-Infective Evasion And Pharmacoepidemiology Research Team, Centre De Recherche En Épidémiologie Et Santé Des Populations, Univ. Paris-Saclay, Univ. Versailles St Quentin-En-Yvelines, Inserm; Epidemiology And

Modelling Of Antimicrobials Evasion (emae), Institut Pasteur, Univ. Paris-Cité, Paris, France

Context: Despite the lack of marketing authorization, proton pump inhibitors (PPIs) are frequently prescribed for treatment of gastroesophageal reflux (GER) in infants under one year of age. In March 2024, the French National Authority for Health (HAS) issued a guideline on care appropriateness emphasizing that PPIs should be reserved for confirmed pathological GER.

Objectives: The aim of this study was to assess the impact of the HAS's guideline publication on PPI prescriptions for infants under one year of age in France.

Methods: The study used data from the French National Health Data System (SNDS). All children who received at least one dispensing of a PPI before 12 months of age were included. Characteristics of children, prescribers, and dispensings were described from 2022 to 2024. Segmented linear regression models with autocorrelated errors were applied to assess the impact of the publication on monthly volumes of PPI dispensings, expressed per 1,000 live births, from January 2015 to April 2025.

Results: Between 2022 and 2024, 188,052 infants were exposed to PPIs. The median age at treatment initiation was 2 completed months (interquartile range [2–4]). Treatment initiations were most commonly prescribed by private paediatricians (36.6%), followed by private general practitioners (32.4%), and hospital-based prescribers (24.9%). Publication of the guideline was not associated with statistically significant changes in PPI dispensing volumes across all prescribers. However, among general practitioners, publication of the guideline was linked to a significant decrease in dispensing volume (change in level: -0.36; 95% confidence interval [-0.64; -0.08], p=0.01) when compared with the pre-intervention period.

Discussion: Although no statistically significant changes in overall PPI dispensing were observed, the study highlighted a favourable impact of the guideline on PPI prescribing practices among general practitioners.

Conclusion: These findings underscore the importance of assessing guideline uptake by healthcare professionals and tailor dissemination strategies to enhance implementation effectiveness.

ID 150- Exploring the experience of Adapted Physical Activity in adolescents with adolescents with Eating Disorders: a qualitative study

Simon ROUSSEL [(1)] , Aurore TRAMEÇON [(2)], Romain VERDEAU [(2)]

(1) Université De Bretagne Occidentale, Faculté De Médecine & Sciences De La Santé-Centre Hospitalier Universitaire Rennes, Brest , Rennes, France
(2) Université De Bretagne Occidentale, Faculté De Médecine & Sciences De La Santé, Brest, France

Context: Anorexia nervosa (AN) in adolescents is a complex disorder involving psychological, physical, and social dimensions. Physical activity holds an ambivalent role, oscillating between compulsive behavior and therapeutic potential. This study focuses on Adapted Physical Activity (APA) as a therapeutic tool for adolescents. Adapted Physical Activity (APA) may serve as a valuable therapeutic tool for adolescents.

Objectives: This study aims to explore adolescent's representations and perceived effects of APA on body image, eating behaviors, and social relationships.

Methods: This is a qualitative study conducted through semi-structured interviews with ten adolescents aged 14 to 17 years, receiving treatment for AN at the University Hospital of XXX. Interviews were recorded, fully transcribed, and analyzed using an interpretative phenomenological analysis (IPA) method. The main themes included illness history, sporting activities, perceptions of APA, and its potential effects.

Results: Adolescents described APA as a safe and structured environment conducive to positive bodily reappropriation. Reported benefits included improved self-image, a reduction in pathological eating behaviors, and a restored connection between physical activity and nutrition. Beyond

these effects, participants highlighted a renewed sense of vitality, greater emotional regulation, and enhanced self-confidence through gradual and supervised movement. APA was perceived as a vehicle for resocialization and therapeutic alliance, fostering trust with both healthcare providers and parents. These benefits appeared highly dependent on the timing of introduction, the proposed framework, and the quality of supervision, underlining the need for careful integration into treatment pathways.

Discussion: The study confirms the therapeutic benefits of APA, according to current literature. It emphasizes the importance of an individualized approach focused on listening to the patient's needs and rhythm. Adolescents reported enhanced vitality, emotional regulation, and renewed self-confidence, which together contribute to a more sustainable recovery process. APA appears not only as a physical rehabilitation tool but also as a psychosocial mediator, reinforcing therapeutic alliance and family trust.

Conclusion: When introduced at the right time, APA supports both physical and social recovery of adolescents with AN. Its integration into multidisciplinary care pathways may enhance outcomes and should be further explored in clinical practice.

ID 87- Raising Awareness among Health Professionals about Early Shared Reading: A Lever for Child Health Prevention

Isabelle ETTORI, Clémence DAVAL

Université De Tours, Tours, France

Context: Shared reading of picture books is a well-established early interaction supporting language, cognitive and socio-emotional development. Despite strong evidence and public health recommendations during the first 1000 days in XXX, many parents remain unaware of this practice, and primary care providers receive no formal training on early shared reading.

Objectives: To assess whether a brief sensitization initiative led by a speech and language therapist could improve primary care professionals' knowledge and practices regarding early shared reading.

Methods: This mixed-methods prospective study was conducted with multidisciplinary primary care teams practicing coordinated care. Seven group interventions were delivered during staff meetings. The initial session included an illustrated oral presentation, a live read-aloud and a brief literature overview. In several sites, shared-reading sessions in waiting rooms were also facilitated. Knowledge and professional practices were assessed through pre- and post-intervention questionnaires. Descriptive analyses were performed, and qualitative notes from clinical observations enriched interpretation.

Results: Eighty-five percent of respondents reported no previous training on early shared reading. Following the intervention, participants showed increased theoretical knowledge and a stronger intention to integrate shared reading into child follow-up. Professionals who also observed waiting-room reading sessions demonstrated greater improvement: they reported better understanding of developmental mechanisms involved, increased confidence in recommending books to families, and enhanced perception of their preventive role. They also more often reported reorganizing or enriching their environment to make books accessible.

Discussion: A short, low-cost intervention improved awareness and preventive motivation among primary care professionals. Direct exposure to shared-reading practice appeared particularly impactful, suggesting experiential learning fosters adoption. These findings support involving speech and language therapists in interprofessional prevention actions addressing early language and literacy. The small, convenience sample and absence of control group limit generalizability. Self-reported measures may overestimate behavioural change, and follow-up was short, preventing assessment of sustained practice changes or family outcomes

Conclusion: Brief sensitization sessions led by speech and language therapists can strengthen primary care professionals' engagement in promoting early shared reading, contributing to prevention in the first 1000 days and helping reduce socio-developmental inequalities.

ID 2083- Participants' experiences of walking groups organised within coordinated primary care structures: a qualitative study in progress

Guillaume FORTIN, Joséphine BERTHAUX

Upec, Torcy, France

Context: Health promotion is a key lever for improving population health while supporting the sustainability of healthcare systems. In primary care, physical activity is recognised for its physical, psychological, and social benefits. Within some coordinated primary care structures, walking groups have been developed as health promotion initiatives outside the formal framework of prescribed adapted physical activity. However, participants' lived experiences of these groups remain underexplored, particularly regarding social connection and health promotion.

Objectives: To explore the lived experiences of patients participating in walking groups organised within coordinated primary care structures, focusing on their motivations, expectations, and perceived benefits.

Methods: This is an ongoing qualitative study. To date, seven semi-structured individual interviews have been conducted with walking group participants, along with one participant observation of a walking session. Participants were recruited through purposive sampling. Interviews were audio-recorded and transcribed verbatim. Data collection is ongoing and will continue until data saturation is reached. A thematic analysis will be conducted iteratively, integrating interview and observation data. Final results are expected in the first half of 2026 and will be available at the time of the conference.

Results: Preliminary findings suggest that participants primarily value walking groups as opportunities to reduce social isolation and foster social connections, sometimes more than for physical activity itself. Relational and convivial dimensions appear central to participants' experiences. While physical activity is recognised as beneficial, it often seems secondary to motivations related to meeting others and belonging to a group.

Discussion: These findings suggest that walking groups within coordinated primary care structures may function primarily as social and relational health interventions rather than solely as physical activity programmes. Ongoing analysis will further explore these dynamics and their implications for primary care practice.

Conclusion: Exploring participants' experiences of walking groups in primary care provides insights into their potential role in promoting social connection and global health. Final results will help inform the development of health promotion practices in coordinated primary care.

Corresponding author: Joséphine Berthaux, josephine.berthaux@etu.u-pec.fr

ID 2063- Patients' perceptions of the carbon footprint of non-pharmacological care in primary care: a qualitative study

Guillaume FORTIN [(1)] , Marianne FOEILLET [(2)]

(1) Upec, Torcy, France
(2) Upec, Créteil, France

Context: Climate change is a major public health challenge, to which healthcare systems contribute through greenhouse gas emissions. In primary care, decisions regarding diagnostic tests, paramedical care, medical devices, and care-related transport are frequent and cumulative, yet their environmental impact remains poorly explored from patients' perspectives. Understanding how patients perceive non-pharmacological care is essential to support sustainable primary care practices without compromising quality or access to care.

Objectives: To explore patients' perceptions of the carbon footprint associated with non-pharmacological care in primary care, focusing on perceived responsibility, individual agency, and the role of healthcare professionals.

Methods: A qualitative exploratory study was conducted using semi-structured interviews with adult primary care patients, recruited through purposive sampling to ensure diverse profiles. Interviews were audio-recorded, transcribed verbatim, and analysed using thematic analysis. Data collection and analysis were iterative. Data saturation was reached after the tenth interview, and two additional interviews confirmed saturation. Researcher triangulation enhanced analytical credibility. This study is part of a broader two-part qualitative programme examining patients' perceptions of the carbon footprint of healthcare consumption in primary care.

Results: Patients reported heterogeneous awareness of the carbon footprint of non-pharmacological care, often marked by cognitive dissonance between environmental concern and limited perceived capacity to act. Everyday ecological gestures were described as individual responses to an issue perceived as collective, leading to strategies of compensation or personal balance. Individual agency was often perceived as limited, sometimes resulting in inaction. Physicians were identified as central actors in care decisions and key mediators for integrating environmental considerations. While patient autonomy in health was familiar, its extension to environmental dimensions remained emergent. Clear, contextualised information was viewed as a lever for empowerment.

Discussion: Findings highlight tensions between environmental awareness, individual responsibility, and systemic constraints, underscoring the role of the physician–patient relationship in supporting shared decision-making that integrates environmental considerations into routine care.

Conclusion: Exploring patients' perceptions of the carbon footprint of non-pharmacological care provides insights for promoting sustainable practices in primary care. Through information and shared decision-making, general practitioners may strengthen patients' perceived agency and support care that is appropriate, acceptable, and environmentally sustainable.

ID 1748- Patients' opinion on ecological actions in general practice : A quantitative study in french population

Emmanuel INDAUD, Apolline ESSEAU, Bastien DUPONT, Maria GHALI

Université D'angers, Angers, France

Context: Climate change and pollution are well known for their negative impact on human health. The health sector represents 1 to 5% of the global ecological footprint, and up to 9% in France. Primary care plays a central role in addressing climate change, through prevention and its close relationship with the population. In this context, in 2019, WONCA called on general practitioners (GP) to take action and be prepared for the health consequences of the climate change. Several theses have studied the ecological actions undertaken by GP in France. Some studies show a reluctance to adopt such measures, largely due to concerns about patients' views. However, we found limited literature addressing patients' opinion regarding these ecological actions.

Objectives: Our objective was to assess the opinions of GP patients regarding ecological actions implemented in GP surgeries in xxx.

Methods: We conducted a quantitative, descriptive study using a questionnaire proposed to patients of participating GP.

Results: We collected 553 responses between July and December 2025. Of the respondents 77% were female, and ages ranged from 18 to 94 years (mean 43,2 years ; standard deviation 16,0 years). Participants described themselves as totally (4,9%) or mainly (31,8%) engaged in ecological concerns, with 44,1% reporting moderate engagement. Regarding the use of cleaned or disinfected medical supplies, respondents "totally agreed" or "rather agreed" at the following rates : 71,1% for ear specula, 41,8% for vaginal specula, 49,2% for spatulas, and 60,6% for suturing instruments. Additionally, 74,7% of patients agreed to be examine without disposable examination sheet and 71,8% agreed to replace it by bringing a personal towel. A large majority (83,5%) supported modifying their treatment for a more ecological alternative, and 78,3% were open to dematerialized prescriptions.

Discussion: This study suggests that patients are generally supportive of ecological changes in their doctor's practice. However, several biases must be considered (recruitment and social desirability bias): the sample is not representative of the general population nor of the typical patient population of a GP.

Conclusion: These findings may encourage more GP to adopt ecological measures, knowing that patient opinion (one of their main concern) appears largely favourable.

ID 979- Assessment of physico-chemical water parameters and health risk characterization in the mining areas of Siguiri, Guinea.

Aly Badara TOURE, Mariama Sadjo DIALLO, Alexandre DELAMOU

African Center Of Excellence For The Prevention And Control Of Communicable Diseases (cea-Pcmt), University Gamal Abdel Nasser Of Conakry, Conakry, Guinea, Conakry, Guinée

Context: Artisanal and small-scale gold mining (ASGM) is a major source of environmental contamination in West Africa, particularly in Guinea, where mining activities release substantial amounts of toxic metals into surrounding ecosystems. In Siguiri, where ASGM is widespread, local communities rely heavily on groundwater and river water for daily consumption, increasing their vulnerability to metal exposure

Objectives: The objective of this study is to comprehensively assess water contamination and associated health risks in the artisanal mining areas of Siguiri, Guinea.

Methods: A cross-sectional analytical study was conducted during both rainy and dry seasons in Siguiri. We collected 36 water samples (12 boreholes, 24 river points) from three major mining sites. Samples were analyzed for eight heavy metals (mercury, lead, aluminium, cadmium, nickel, manganese, copper, iron) using UV-visible spectrophotometry. Health risk assessments followed the US EPA methodology, calculating Hazard Index (HI) for ingestion and dermal exposure, as well as Cancer Risk (CR_ing). Multivariate statistical analyses identified contamination patterns and vulnerable populations.

Results: Heavy metal concentrations exceeded WHO guidelines, particularly during rains. Nickel and manganese exceeded limits by 10-20 fold, while mercury and lead surpassed limits by >50-fold at some sites. Water hazard index peaked at 56.3. Non-carcinogenic ingestion risks for children reached alarming values of 476 (dry season) and 409 (rainy season) far exceeding the acceptable risk threshold of 1. Carcinogenic risks exceeded EPA thresholds ($>10^{-4}$) for nickel, lead, and cadmium, with children being 4-10 times more vulnerable than adults. Multivariate analysis identified three contamination clusters: "Low Toxicity (Dry Season)," "Moderate Toxicity (Rainy Season)," and "High Toxicity (Oudoula)."

Discussion: The findings indicate severe and persistent contamination driven by mining runoff, particularly during the rainy season. The disproportionate burden on children underscores their vulnerability due to higher intake per body weight. The magnitude of both non-carcinogenic and carcinogenic risks suggests long-standing, cumulative exposure rather than isolated contamination events.

Conclusion: Our findings demonstrate significant health risks, particularly for children, necessitating urgent interventions. We recommend installation of water treatment systems, tailings containment structures and phytoremediation using local metal-accumulating plants. These measures align with SDGs 3, 6, and 12, supporting Guinea's national development agenda while protecting vulnerable communities.

ID 976- Prescribing nature – a breath of fresh air in therapy

Jean DOUBOVETZKY [1] , Eva KOZUB [2]

(1) Groupe Santé Planétaire Du Cmg, Albi, France
(2) Groupe Santé Planétaire Du Cmg, Castelnau Magnoac, France

Context: Contact with the natural environment has proven benefits for mental and physical health. Nature prescriptions help people who need them to spend more time in nature. This practice is growing in popularity in many countries. The Planetary Health Working Group of the College of General Practitioners (CMG) has produced a guide to help healthcare professionals make use of this simple tool.

Methods: This CMG guide presents the benefits of experiencing nature, drawing on scientific references, the key concept of co-benefits (including physical activity and healthy eating), the practical aspects of prescribing nature, as well as potential obstacles and ways to overcome them.

Originality: Nature prescription involves prescribing (preferably in writing) all sensory contact with nature, from simple observational contact such as looking at a picture or looking out of a window, to immersive and active experiences such as swimming in the sea or

Lessons learned and future implication: The benefits of nature prescription are individual (improved physical and mental health) and also collective and global, through their impact on the decisions and behaviours of individuals and population.

Discussion: Given its benefits and the low cost of prescribing nature, healthcare professionals are eagerly awaiting the development of policies tailored to its implementation and management. It would be interesting to continue evaluating this simple intervention.

Conclusion: 'Nature prescription is a non-pharmaceutical intervention that is inexpensive and easy to implement in primary care. It is practised in several countries around the world. It has many benefits for human health.' This guide, which aims to promote its practice, is most welcome.

ID 369- carbon footprint of general practitioners' prescriptions

Charlotte SIEFRIDT [1] , Morgane BULTÉ [2]

(1) Université Rouen, Romilly Sur Andelle, France
(2) Université Rouen, Rouen, France

Context: The healthcare sector is responsible for nearly 8% of national greenhouse gas (GHG) emissions, estimated at 48.6 $MtCO_2eq$. Medicines contribute 29% of these emissions, ahead of medical devices (21%) and transport (13%). General practice accounts for 23% of this total. In Normandy, the GHG footprint of general practitioners (GPs) has been assessed: in 2022, an average practice emitted around 12 tonnes of CO_2eq, excluding prescriptions and patient transport. The objective of this study was therefore to evaluate the GHG emissions associated with prescriptions issued by general practitioners in Normandy.

Methods: We conducted a quantitative descriptive study using a GP's data warehouse (PRIMEGE). GHG emissions linked to prescribed medicines were calculated using ECOVAMED database, which applies life cycle analysis to assess environmental impacts from production to disposal. Only solid oral dosage forms were included, as data for other forms were unavailable.

Originality: To date, no study in France has objectively quantified the environmental impact of medical prescriptions. This work contributes to the development of eco-prescribing guidelines.

Lessons learned and future implication: Prescriptions from 61 GPs were collected in 2022. 181,354 prescriptions were analysed from 151,179 consultations. Their associated emissions totalled 257,101 $kgCO_2eq$, corresponding to 4,215 $kgCO_2eq$ per GP and 1.7 $kgCO_2eq$ per consultation. Cardiovascular d

Discussion: GHG emissions from GPs' prescriptions are equivalent to 145 return flights between Paris and New York. Because only solid oral forms were analysed, many frequently prescribed molecules could not be included. Further studies are required

to fully determine the environmental impact of GPs' prescriptions. Based on this work and other studies eco-prescription concepts have been developed : deprescribing, ensuring appropriate medication use, take into account environmental toxicity and carbon footprint. For carbon footprint, five main principles have been suggested : favouring dry oral forms, limiting pressurised inhalers, favouring drugs with the lowest effective daily doses within the same therapeutic class, favouring drugs combining several active substances and choosing dosing regimens with minimal necessary doses

Conclusion: General practitioner's prescriptions generate significant greenhouse gas emissions. Applying its principles of eco-prescription would reduce the carbon footprint of the healthcare system.

ID 354- Nature Prescription for Health : what do french General Practitioners think of it ?

Juliette ZIMMERMANN [(1)] , Orphyre FOSTIER [(2)]

(1) Alliance Santé Planétaire, Paris, France
(2) Faculté De Médecine, Maïeutique Et Sciences De La Santé, Lille, France

Context: There is a growing recognition that nature exposure is beneficial for human health. Nature prescription programs have been implemented in many countries to address the high burden of non-communicable diseases. Nature prescription is a low-cost health intervention which can easily be used on its own or as a complement to drug treatments. Prescribing nature has several co-benefits, such as encouraging pro-environmental behaviours. However, in France, nature prescriptions are not routine in primary care practice.

Objectives: To identify enablers and barriers surrounding nature prescriptions in primary care in XXX, France.

Methods: For this qualitative study inspired by grounded theory, we interviewed GPs (n=11) in XXX. Purposive sampling was applied until data sufficiency was reached.

Results: Facilitators to nature prescribing include awareness of the health benefits of nature, regular personal contact with nature, interest in an alternative to medication, acknowledgment of the important role played by GPs in planetary health, easy, free and local implementation, and positive feedback from patients. Some participants questioned the existence of scientific evidence of the benefits of nature. Some of them feared side effects such as increase in skin cancers. Lack of time, lack of peer support and acceptance of the value of nature as a support for wellbeing, difficulties to access nature for some patients were reported as barriers. Participants identified a need for accessible theoretical resources, policy statements and national guidelines. They would benefit from help by other care givers and an easier access to nature for their patients.

Discussion: The strength of this study lies in addressing an unexplored topic in France and promoting planetary health; limitations include the low number of participants, variable interview depth, and challenges inherent to qualitative analysis. Findings align with international literature.

Conclusion: The uptake and delivery of nature prescriptions is influenced by the prescriber's own relationship with nature, personal experience and/or knowledge of the benefits of nature for health. To lower the barriers we highlighted, it is critical that governments and local decision-makers support the greening of communities especially in urban areas, and that official guidelines be drawn up. Broader public health campaign would allow nature prescription to deploy.

ID 1429- Pneumococcal vaccination: evaluation of vaccine coverage and knowledge among adults at risk of invasive pneumococcal infections in Ajaccio area

Nebahat Bilge BALIM [(1)] , Giray KOLCU [(1)], Funda YILDIRIM BAŞ [(1)], Melike ALSANCAK [(2)], Selma KAYA [(3)], Hatice Belkıs BULUT [(4)]

(1) Süleyman Demirel University, Isparta, Türkiye
(2) Etimesgut District Health Directorate, Ankara, Türkiye
(3) Tokat Gaziosmanpasa University, Tokat, Türkiye
(4) İstanbul Bakırköy Dr Sadi Konuk Education And Research Hospital, İstanbul, Türkiye

Context: With the rapid aging of the global population extending healthy lifespan, reducing the burden of chronic diseases and preserving functional capacity in older age have become key priorities for health systems.Longevity is a multidisciplinary concept that emphasizes not only extending life expectancy but also ensuring that extended life is lived in good health.Primary health care lies at the core of longevity strategies due to its role in early risk detection and the implementation of behavioral change interventions.

Objectives: To define the concept of longevity, evaluate its importance within primary health care, examine current trends based on the most highly cited studies of the last decade and develop practice-oriented recommendations.

Methods: A thematic literature analysis was conducted using Scopus, Web of Science and Google Scholar databases. Articles published between 2015 and 2025 with ≥300 citations or published in high-impact journals were included. Inclusion criteria focused on longevity, healthy aging, lifestyle interventions and the impact of primary health care.

Results: Strong evidence supports the effectiveness of lifestyle-based interventions in promoting longevity. Caloric restriction, intermittent fasting and regular physical activity improve metabolic markers and reduce mortality. Increased primary care physician density has been shown to be significantly associated with higher life expectancy. Early identification of age-related conditions such as multimorbidity and frailty in primary care yields favorable outcomes.

Discussion: Highly cited literature from the past decade reveals that longevity is not only a biological phenomenon but also a process closely linked to the structure of health care systems. Primary health care represents the most effective platform for longevity interventions due to its role in early risk detection, lifestyle modification, behavioral counseling and continuity of care.While the family medicine model in XXX provides a strong foundation, challenges remain, including high workload, limited age-specific protocols, insufficient data integration and lack of multidisciplinary teams.

Conclusion: Enhancing longevity requires not only an understanding of biological aging but also a strong and well-structured primary health care system. In XXX, primary health care holds significant potential for the early management of age-related risks through cost-effective and high-impact lifestyle interventions.

ID 877- Meningitis B vaccination in France before and after inscriptions in vaccination calendar

Hsiu WU, Pei-Ying WU, Yi-Wen TSAI

Department Of Family Medicine, Chang Gung Memorial Hospital, Linkou, No. 5, Fuxing St., Guishan Dist., Taoyuan City, 333, Taiwan, Taoyuan, Taïwan, République de Chine

Context: Overweight and obesity are well-established risk factors for metabolic syndrome (MetS) and cardiometabolic diseases. Although the National Health Insurance program in Taiwan offers health checkups to facilitate early disease detection, the specific effectiveness of these checkups in preventing disease progression among the high-risk obese population remains uncertain.

Objectives: This study aimed to evaluate whether utilizing health checkups reduces the incidence of MetS and related cardiometabolic risks (hypertension, hyperglycemia, and hyperlipidemia) in overweight/obese adults.

Methods: We conducted a multicenter retrospective cohort study using a clinical research database in Taiwan from 2003 to 2015, with follow-up through 2024. The study population included adults aged ≥ 18 years with a BMI ≥ 24 kg/m² who had not been diagnosed with MetS or cardiometabolic diseases prior to the index date. Participants were divided into an intervention group (received preventive health checkup) and a control

group. A 1:4 Propensity Score Matching was applied, adjusting for age, sex, and baseline BMI. Cox proportional hazards models were used to estimate adjusted hazard ratios (aHRs) and 95% confidence intervals (CIs).

Results: A total of 14,615 matched participants were included (2,923 in intervention group and 11,692 in control group). Overweight/obese adults who utilized preventive health checkups had a significantly lower risk of developing metabolic syndrome (adjusted hazard ratio [aHR]: 0.69; 95% CI: 0.64–0.73; p<0.0001) compared to the control group. Moreover, participants who received health checkups experienced a significant reduction in the incidence of hypertension (aHR: 0.92; 95% CI: 0.87–0.97; p=0.002).

Discussion: These findings indicate that adult preventive health checkups provide benefits beyond disease detection along. The observed reduction in incident MetS and hypertension suggests that these health checkups may serve as effective primary care touchpoints for early life style counselling, and timely medical advice, thereby that effectively lower cardiometabolic risk among overweight and obese adults.

Conclusion: Utilization of adult preventive health services was associated with a significant reduction in the incidence of metabolic syndrome and hypertension among overweight and obese adults. Public health policies should further encourage the utilization of these services to mitigate the burden of obesity-related chronic diseases. Keywords: Preventive Health Checkups; Obesity; Metabolic Syndrome; Cardiometabolic Risks

ID 919- Evolution of HPV vaccination prevalence and associated socio-demographic factors in high-income countries (2006–2024): a systematic review

Timothy WHELAN [(1)], Neha SHAH [(1)] , Frances CHIVERS [(1)], Patrick WILLS [(1)], Navoda RAJAN [(1)], Louay AL-MUKHTAR [(1)], Oliver CULE [(2)]

(1) Newport Health Centre, Newport, Isle Of Wight, Royaume-Uni
(2) The Bay Medical Practice, Sandown, Isle Of Wight, Royaume-Uni

Context: Under-treated hypothyroidism can delay conception and impair fetal development. Despite primary care management, increased thyroid hormone needs in early pregnancy are often missed due to non–trimester-specific reference ranges, adherence issues, and delayed antenatal care. This highlights the need for optimal pre-conception control, closer pregnancy monitoring, and clear advice to increase replacement therapy as soon as pregnancy is confirmed.

Methods: We conducted an iterative audit of hypothyroid women of reproductive age in a UK-representative general practice (population 24,000). An initial audit (2020–2023) showed poor annual TFT monitoring (27/70 patients), partly attributed to the COVID-19 pandemic. Following remedial measures, monitoring improved in 2024 (63/70). The 2025 audit identified 27/86 patients requiring further attention. Results of the 2026 audit will be presented to complete the study.

Originality: Previous studies have urged the importance of monitoring hypothyroid patients with at least annual TFT and action on the results. Advice has included increasing the dose of replacement therapy by 20% as soon as pregnancy is confirmed. Congenital hypothy

Lessons learned and future implication: Proactive monitoring, early dose adjustment, and education improve pregnancy outcomes. Advice from NICE, British Thyroid Foundation, and has recently been added to our local patient website. Laboratories are to be encouraged to state any replacement thera

Discussion: This audit highlights important gaps in the routine management of hypothyroidism in patients of child-bearing potential. Of the 86 patients reviewed, 27 (31%) required further attention due to suboptimal thyroid function monitoring and the need for repeat blood tests and follow-up. This finding suggests that a substantial

proportion of patients may enter pregnancy with inadequate thyroid control, placing both maternal and fetal outcomes at risk.

Conclusion: Levothyroxine dose should be increased immediately on pregnancy recognition, ideally in primary care, with specialist referral if target levels are not achieved. Proactive monitoring, pre-conception counselling, and improved primary care awareness are essential to optimise maternal and fetal outcomes.

ID 813- Knowledge of the HPV vaccine among boys aged 11-19 years and their parents in Limousin

Loïc DRUILHE, Emeline BIZIEUX, Christelle CHAMANT

Médecine Générale, Tours, France

Context: Sexual health is one of the objectives of France's national health policy. Condom use is declining and the incidence of sexually transmitted infections (STIs) is increasing. High school students are particularly concerned as they represent a high-risk population, their knowledge of the risks and means of prevention in relation to sexuality is insufficient. Sex education is part of the high school curriculum, but there is no validated intervention with proven effectiveness on behaviour and knowledge in relation to sexuality.

Objectives: In 2023, an intervention was carried out in vocational high schools in the french department of XXX. It consisted of 777 students completing a questionnaire about their knowledge and behaviours in terms of sexuality, followed by a discussion on this topic with a resident in general practice. The aim of our study was to evaluate the effectiveness of this brief intervention in terms of sexual behaviour and knowledge.

Methods: This was an observational study of vocational high school students who had previously participated in a sexuality intervention in 2023 with a resident in general practice. Condom use, emergency contraception use, number of unwanted pregnancies, STI screening, STI infection, and sources of information on sexuality were compared for the same group one year after the first intervention.

Results: In 2024, 492 vocational high school students responded to the questionnaire. One year after the intervention, there was a statistically significant improvement in the number of STI screenings, emergency contraception use, HPV vaccination, and high school students' knowledge of sexuality. However, there was still low condom use and persistent gaps in knowledge about contraceptive methods.

Discussion: This study highlights an improvement in knowledge and a trend towards improved sexual behaviour one year after the intervention by a resident in general practice.

Conclusion: Improving and standardising this intervention and studying it on a larger sample, including general secondary schools, would make it possible to design a brief, effective and reproducible intervention for high school students in the area of sexual health.

ID 271- Vaccine hesitancy among migrant populations in Europe: a mixed-methods systematic review.

Majdi LAATAR

Ministry Of Health / Istanbul Medipol University, Istanbul, Türkiye

Context: Primary care is an ideal spot to offer preventive care services along with chronic disease management. However, behind the scenes, these two areas often aren’t well connected limiting what, they could achieve if well united together, as matter of fact limiting the potential of early detection of risk. Recent research emphasizes that integration of prevention, screening and risk counselling included within chronic disease management is able to make primary care work better and improve system efficiency, while saving time and effort in a long-term perspective.

Objectives: To review and synthesize evidence from the last two years that looked at approaches, methods, and implementation obstacles for embedding preventive medicine into chronic disease management within primary care clinics.

Methods: We conducted a narrative review of peer-reviewed literature, policy papers, and implementation research published during the last two years. Key sources included systematic reviews, meta-analyses, along with interviews focused on team-based health setups in local clinics.

Results: Multicomponent approaches have shown better results in fulfilling preventive services. Research in underserved areas and case studies show cultural collaborations is needed along with updated processes to the region and its habitants. However, obstacles including mismatched rules, poor leadership, short resources, and inconsistent regulations has impeded ongoing progress. Initiatives to reach agreement, such as directions on CGM implementation have proven that, with accurate training and assistance, primary care is able to effectively adopt preventive innovations.

Discussion: Privileging prevention while treating chronic disease may work perfectly. However, this still need several actions organized together, besides that, it also needs clear strategies from doctors. Hospitals and primary care clinics as well need to support this by providing better setups and rules in order to make it happen and work efficiently; failing to do so would affect the progress.

Conclusion: Integrating preventive medicine within chronic disease care in primary care is not only feasible, but also turns out to work perfectly. To make it happen, health systems should support multicomponent implementation strategies, build dedicated roles, as a matter of fact: prevention practitioners, at the same time respecting also cultural differences, by fostering culturally tailored models in underserved communities.

ID 153- Perception of harm from alcohol consumption in the young population Observational study

Aleksander BIESIADA [(1)] , Karolina KŁODA [(1)], Mateusz BABICKI [(2)], Agnieszka MASTALERZ-MIGAS [(2)]

(1) Polish Society Of Family Medicine, Wroclaw, Pologne
(2) Wrocław Medical University, Wroclaw, Pologne

Context: The “My Health” program is a preventive healthcare service for individuals aged 20 and older, implemented in Primary Care in Poland. The program includes health assessments, preventive tests, health education, and the creation of an Individual Health Plan. One of the key components of the Plan is vaccination recommendation. The program aims to improve vaccine uptake among adults.

Objectives: This study evaluates how the program influences the uptake of pneumococcal, COVID-19, seasonal flu, and RSV vaccinations. We hypothesize that patients receiving vaccination recommendations within their Care Plan are more likely to complete these vaccinations than those outside the program.

Methods: This is an observational, comparative study. The intervention group includes patients aged ≥20 who have participated in the “My Health” program, which involves completing a health questionnaire, undergoing tests, attending a summarizing consultation, and receiving a Plan with vaccination recommendations. The control group consists of patients of the same age, registered in the same PC facilities, who have not participated in the program. Data collection is based on a CAWI (Computer-Assisted Web Interview) survey administered to healthcare personnel, who will identify patients with vaccination recommendations and report the proportion of those who have received vaccinations for pneumococcal disease, COVID-19, seasonal flu, and RSV. Statistical analysis will compare vaccination rates between the two groups, adjusting for confounders such as age, sex, chronic diseases, and prior vaccinations.

Results: Preliminary data from two PC facilities include N=542 patients in the intervention group and N=302 in the control group. Early findings suggest that participation in the “Moje Zdrowie” program is associated with a higher vaccination uptake (for flu vaccine: 23% versus 11%, $p<0.05$). Full data will be presented.

Discussion: The preliminary results suggest that integrating vaccination recommendations into the "My Health" program may improve vaccination uptake among adults. Future research should focus on addressing barriers to vaccination and optimizing health system interventions to enhance adherence to vaccination recommendations in primary care.

Conclusion: Participation in the "My Health" program appears to be an effective strategy for increasing adult vaccination rates. Full analysis will lead to recommendations for integrating vaccination recommendations into primary care programs.

Screening and preventing

ID 2206- Deviations from good clinical research practices in a randomized controlled trial in primary care: monitoring of "Statins in the Elderly"

Jean-Philippe JOSEPH [(1)] , Mahanya BERNTON [(1)], Nicolas ROUSSELOT [(1)], Fabrice BONNET [(2)], Pierre POULIZAC [(3)]

(1) Département De Médecine Générale Université De Bordeaux, Bordeaux, France
(2) Service De Médecine Interne-Hôpital Saint-André, Bordeaux, France
(3) Drci-Chu De Bordeaux, Bordeaux, France

Context: Clinical trials are required to comply with overarching regulatory standards to ensure data quality and validity of results. For trials conducted in primary care, ensuring data quality can be particularly challenging due to the decentralization of study sites, limited research infrastructure, and constraints related to routine clinical practice.

Objectives: The aim of our study was to analyze the results of on-site monitoring visits from a clinical trial conducted in primary care, Statins in the Elderly (SITE), in order to quantify and describe deviations from good clinical research practices (GCRP).

Methods: SITE study is a multicenter randomized clinical trial in which 304 general practitioner investigators recruited 1209 patients in France from June 2016 to December 2029 with 3 years of follow-up. Study monitoring was conducted remotely using the electronic Case Report Form. Two on-site monitoring visits were planned. The proportion of non-conformities, classified as minor, major, and critical, and the investigator profiles, including age, clinical research experience, and the number of patients enrolled, were recorded.

Results: Almost all investigators (300/304) received queries related to non-compliance with GCRP. These primarily concerned source documents, but also the manner in which the electronic case report form was completed. A total of 5746 non-conformities were recorded, with a median of 5 per investigator. Minor (22%), major (77%), and critical (1%) deviations were less frequent when the investigator was younger. 227 investigators included at least two patients, with a mean of 4.77 deviations per investigator, compared to 9.53 for the 77 investigators who included only one patient ($p<0.001$).

Discussion: Based on these results, targeted strategies could improve data quality in clinical trials conducted in primary care, notably through enhanced training and the simplification of data collection processes. It would also be beneficial to foster a culture of information sharing on data quality in order to establish more precise standards than the broad guidelines that currently guide clinical research practice.

Conclusion: In France, primary care setting represents a challenge for clinical research. In order to improve data quality, data collection should be facilitated for optimal investigators participation in clinical research.

Corresponding author: Mahanya Bernton, mahanya.bernton@u-bordeaux.fr

ID 1647- Health prevention examinations in the practice of private general practitioners in northern France

Camille OBERT-MARBY, Elliot LYS

Faculté De Médecine Maieutique Et Sciences De La Santé, Lille, France

Context: In (XXX), preventive health examinations are offered at health centres to everyone. Following

the check-up, a report may be sent to the patient's general practioner (GP). Fully covered by the National Health Service, this screening involves significant costs, raising questions about its place in primary care.

Objectives: To determine the value of preventive health assessments and their integration into the practice of GPs in (XXX).

Methods: Qualitative study using semi-structured individual interviews conducted with private GPs in (XXX) who had received at least one preventive health assessment report for one of their patients. Audio recordings followed by full transcripts were used to collect verbatim statements, which were analysed on an ongoing basis using phenomenology, with triangulation of coding. The interviews were continued until sufficient data had been collected.

Results: The fourteen participants expressed mixed opinions about this preventive consultation. It sometimes appears to be a useful tool for screening and reintegrating patients into the care pathway, particularly those who are not receiving regular follow-up. However, although the report is considered easy to read, it is not very useful for patients who are receiving regular follow-up, as it is redundant and does not contain any significant abnormalities. The electronic transmission of results, better coordination between health centres and GPs, and targeting the system at vulnerable users or those who do not need to consult often will optimise the resources dedicated to prevention in (XXX).

Discussion: The prevention assessment seems relevant but raises questions among GPs. In a healthcare system under pressure, it encourages better interprofessional cooperation and a change in the care relationship. General practitioners must learn to delegate their preventive healthcare responsibilities to other professionals : pharmacists, nurses and health centres, with complete confidence, so that they can focus on priority care tasks. Patients must be prepared to consult outside of any pathological context in order to benefit from time dedicated to individual prevention.

Conclusion: National prevention policy must focus on vulnerable populations or those who are isolated from the healthcare system, and it is necessary to study the current impact of systematic health checks on morbidity and mortality.

Corresponding author: Elliot Lys, elliot.lys@gmail.com

ID 117- What do think GP about medical overuse ?

Amelie RICHARD, Catherine LAPORTE, Elodie CHARUEL

Accept, Uca, Clermont Ferrand, France

Context: Overmedicalisation refers to an excess of medicine with multiple facets: overdetection, overdiagnosis, overtreatment, and excessive care. This overconsumption of medical services has direct consequences for patients and for the planet, including anxiety, iatrogenesis, and antibiotic resistance. What is the opinion of French general practitioners (GP)?

Objectives: To observe and describe the perceptions of GPs and general practice residents (GPR) on overmedicalisation and their proposed solutions.

Methods: A cross-sectional study using a real-time questionnaire (Wooclap®) was conducted among participants at a regional university conference on general practice (May 2025). Descriptive statistics reported quantitative data as means (± standard deviations) for continuous variables and as frequencies (percentages) for categorical variables. A qualitative thematic analysis described the solutions explored through an open-ended question and presented in a word cloud.

Results: Of the 300 conference attendees, 199 responded: 74 practising GPs including 38 university internship supervisors, 37 locum doctors and 92 residents. The average age was 34 (±11). On average, they estimated that 29% (±18) of their daily practice seemed to involve over-medicalisation and 16% (± 14) iatrogenesis. Almost all participants (96%) believed that over-medicalisation was a problem. Of the 455 responses collected regarding solutions, 33% targeted patient therapeutic education, 13% targeted deprescribing, and 12% targeted delisting.

Discussion: The originality of this study lies in its topical subject matter, which was addressed live with a panel of conference attendees. This exploratory aspect limits extrapolation to doctors in the region. The approximately 30% rate of

overmedicalisation and the proposed solutions correspond to findings from German and American studies. Solutions to combat overmedicalisation focused mainly on patients and the healthcare system, as in other studies, with little self-reflection.

Conclusion: .Both GPs and GPRs are aware of overmedicalisation in their practice. However, the solutions proposed, mainly focused on patients and the healthcare system, show that work is still needed regarding the principle of the illusion of unique invulnerability.

Corresponding author: Amelie Richard, amelie.richard@uca.fr

ID 1101- Exploring sun protection habits and perceptions of skin cancer among farmers in XXX: a qualitative study using semi-structured interviews.

Aurore TRAMEÇON [(1)], Éléonore BLANC [(2)]

(1) Ur7479 Spurbo, Département De Médecine Générale, Université De Bretagne Occidentale, Brest, France
(2) Université De Bretagne Occidentale, Brest, France

Context: Skin cancer rates are rising in XXX, particularly in XXX, where the incidence is three times higher than the national average. Farmers are particularly at risk, with the risk of melanoma increasing fivefold in thirty years. They are the target audience for the 'XXX' prevention campaign launched in 2022.

Objectives: Exploring sun protection habits and perceptions of skin cancer among farmers.

Methods: Qualitative study based on semi-structured interviews conducted with farmers in XXX. The interview guide focused on sun protection practices, screening, knowledge of sun risks and the impact of existing campaigns. The interviews were recorded, transcribed and analysed using an approach inspired by grounded theory.

Results: Eight interviews were analysed. Sun protection was limited, intermittent, often partial, and heavily dependent on weather conditions. The risk of sun exposure was underestimated due to practical and economic constraints. Personal perceptions, such as the sensitivity or otherwise of certain areas of the body, influenced preventive behaviour. Exposure to a family history of skin cancer encouraged sun protection. Current campaigns were perceived as insufficiently adapted to the agricultural environment and not impactful enough. Participants suggested more targeted prevention, relayed through direct channels and supported by resource professionals such as general practitioners. Employers also had a role to play.

Discussion: Awareness of the risks associated with sun exposure remains low, contrasting with the reality of significant occupational exposure. To remedy this, prevention strategies must be varied and tailored to the target audience: general practitioners, professional organisations such as cooperatives, and direct channels such as text messages. Furthermore, skin cancer is recognised as an work-related illness for farmers in several European countries, which helps to raise awareness in the workplace. This recognition is currently under consideration in XXX.

Conclusion: Sun exposure is the primary risk factor for skin cancer. Integrating strategies from the start of farmers' working lives is a major challenge in limiting the impact of skin cancer in this particularly exposed population.

ID 918- French screening recommendations: A systematic review

Pierre-Yves MEUNIER [(1)] , Karfala MAIGA [(2)], Denis MAILLET [(3)], Marion LAMORT-BOUCHÉ [(1)], Péron JULIEN [(3)], Letrilliart LAURENT [(1)]

(1) Collège Universitaire De Médecine Générale, Lyon, France
(2) Centre Hospitalier Le Vinatier, Bron, France
(3) Hospices Civils De Lyon, Lyon, France

Context: As a primary care provider and through their patient-centered approach, general practitioners are at the heart of preventive medicine. In France, the Haute Autorité de Santé (HAS) does not publish recommendations specifically dedicated to screening. These are disseminated in various types of guidelines, most

often focused on the general management of a condition. Thus, no comprehensive synthesis of French screening recommendations existed in 2024.

Objectives: To identify HAS screening recommendations, describe their main characteristics, and compare them with United States Preventive Service Task Force (USPSTF) recommendations.

Methods: Systematic review. The HAS and USPSTF websites were screened in January 2023. Recommendations that included a screening recommendation were included. Updated recommendations, recommendations for identifying complications (severity diagnosis) or causes (etiological diagnosis) of a health problem were excluded.

Results: We included 53 HAS recommendations and 67 USPSTF recommendations, covering 74 and 65 conditions respectively. HAS recommended screening for 67 conditions, compared with 30 for the USPSTF; 6 versus 7 conditions were not recommended, and 1 versus 28 were judged to have an uncertain benefit–risk balance. Only 21 conditions were recommended for screening by both agencies. HAS recommended screening for 14 of the 28 conditions for which the USPSTF considered the balance of benefits and harms to be uncertain, and for 33 additional conditions not evaluated by the USPSTF, including 11 neonatal disorders. Only 25% of HAS screening recommendations had a graded level of evidence, 71% of which were based on expert opinion, and screening periodicity was undefined in 26% of them. Most HAS screenings (82%) were opportunistic rather than organized.

Discussion: HAS recommends screening for far more conditions than USPSTF, often on weak or non-graded evidence and within heterogeneous guidelines that complicate retrieval and offer of screenings by general practitioners. These differences reflect the absence of dedicated screening guidelines using a standardized methodology and transparent grading of benefits and harms in France.

Conclusion: French screening policy should be aligned with international best practice. It requires reliable screening recommendations that clearly grade evidence, consider benefits and harms, and support shared decision-making in primary care.

Corresponding author: Pierre-Yves Meunier, pierre-yves.meunier@univ-lyon1.fr

ID 521- General practitioners' perceptions of the feasibility of abdominal aortic aneurysm screening in consultation after brief training and practical experience

Marion GOBÉ [(1)] , Roxane LIARD [(2)], Hervé PICARD [(2)]

(1) Sorbonne Université, Paris, France
(2) Ipso Paris, Paris, France

Context: Since 2013, the French National Authority for Health recommends a one-time, targeted opportunistic screening for abdominal aortic aneurysm (AAA) among at-risk patients. Participation rates, however, remain low. Point-of-care ultrasound (POCUS) is expanding in general practice, and AAA screening performed by trained general practitioners (GPs) demonstrates diagnostic accuracy comparable to that of radiologists. This study is part of the randomized DACEP trial, which compares AAA screening uptake when performed by GPs during consultation versus referral to radiology.

Objectives: To explore GPs' perceptions of the feasibility of AAA screening in consultation after a brief training session and provision of an ultraportable ultrasound device.

Methods: A longitudinal mixed-methods study was conducted over 18 months, combining quantitative and qualitative approaches. Quantitative data were collected through questionnaires administered before and after training, and after 18 months of practice. Perceived feasibility was assessed across three dimensions: integration into consultation, performance, and interpretation. For each screening, a questionnaire evaluated confidence, image quality, and ease of integration. The qualitative component consisted of semi-structured interviews analyzed using an interpretative phenomenological approach.

Results: Twelve GPs were trained and equipped with ultraportable ultrasound devices. Training did

not significantly modify perceived feasibility, and prior ultrasound experience had no measurable effect. However, perceived ease of integration, image quality, and confidence in image interpretation all increased significantly with the number of screenings performed. After 18 months, 64% of GPs wished to continue AAA screening using the device, and all intended to use ultrasound for other indications. Interviews highlighted enthusiasm for POCUS and identified barriers such as time constraints, irregular practice, and low prevalence of eligible patients. Facilitators included regular use, refresher training, and dedicated preventive consultation time.

Discussion: An ambivalence emerged between general practitioners' willingness to integrate AAA screening and the difficulty of implementing it sustainably in practice. The study's external validity is limited because the doctor's patients were mostly young and female and therefore less eligible for AAA screening

Conclusion: Despite strong interest from GPs, sustainable integration of AAA screening remains challenged by organizational barriers. Embedding AAA screening within a dedicated preventive consultation, supported by a multifactorial COM-B–based behavioral approach, could enhance long-term adoption in primary care.

ID 224- Experience, perceptions and process of sexually transmitted infections (STI) management in general practice consultations by general practitioners and patients in France

Emeline PASDELOUP, Manon FOUQUET, Angéline DEHMOUCHE

Université Tours, Tours, France

Context: In XXX, sexually transmitted infections (STIs) have been steadily increasing since the early 2000s. Globally, the WHO estimates that one million people contract an STI every day. Often asymptomatic and potentially responsible for long-term complications, these infections require increased screening among the general population. In this context, health authorities have introduced new recommendations on sexual health. As the first point of contact in the healthcare system, general practitioners play a central role in the detection, prevention and screening of STIs.

Objectives: To explore the experiences, perceptions and approaches to STIs in general practice, from the perspective of patients and general practitioners in the XXX region.

Methods: Qualitative study conducted with patients and general practitioners. Semi-structured interviews were conducted with patients, followed by an analysis inspired by grounded theory. Doctors participated in in-depth interviews, which were analysed using a phenomenological interpretation approach.

Results: Fourteen interviews were conducted (7 patients, 7 doctors). Patients emphasised the importance of the role of general practitioners in STI screening and expressed high expectations in this regard. Several obstacles emerged: embarrassment, age difference, fear of judgement, and lack of time during consultations. Doctors described various strategies for introducing the subject of STIs, notably by taking advantage of opportunities that arise during consultations. They acknowledged that they do not systematically address the subject, particularly with certain profiles such as couples or elderly people. Although they generally stated that they felt comfortable doing so, they adjusted their approach according to patients' reactions and experiences.

Discussion: The results reveal an asymmetry between patients' expectations and doctors' daily practice. The approach to STIs remains conditioned by relational and contextual obstacles, limiting systematic screening, which is nevertheless recommended. Consultations appear to be an area that is still insufficiently exploited for proactive discussion of sexual health.

Conclusion: The study highlights persistent barriers, on the part of both patients and doctors, to addressing STIs in general practice. Better promotion and dissemination of existing measures, as well as structured opportunities to integrate screening into routine practice, could encourage more systematic dialogue about STIs during consultations.

Sexual health

ID 2235- Medical abortion between 7 and 9 weeks of gestation in private primary care: practices, motivations, and barriers from a nationwide survey

Noémie HEYSER

Department Of General Practice, Faculty Of Medicine, University Of Rennes, Vannes, France

Context: During the COVID-19 pandemic, medical abortion between 7 and 9 weeks of gestation (WG) was temporarily authorised in private primary care practices in XXX. This measure was later made permanent by a national law. However, its impact on routine practice in private primary care has not yet been well described.

Objectives: To describe medical abortion practices between 7 and 9 WG in private primary care following a national legal change, and to explore healthcare professionals' motivations and barriers.

Methods: We conducted a nationwide cross-sectional study between June 2024 and July 2025 among profesional authorised to provide medical abortion in private practice. Eligible participants were general practitioners, gynaecologists and midwives; professionals working exclusively in hospitals or health centres were excluded. The survey used an online questionnaire disseminated through professional networks and a paper questionnaire sent by post to 1,667 practitioners identified via national online directories. Descriptive analyses were performed, including comparisons between providers and non-providers beyond 7 WG. Motivations and perceived barriers were explored accordingly.

Results: 938 professionals responded (56.3%). Among participants, 94% reported providing medical abortion beyong 7 WG, with high satisfaction (95%). The sample included 56% midwives, 35% general practitioners and 9% gynaecologists, and was predominantly composed of women (89.6%). Professional specialty influenced practice, with higher uptake among midwives and lower rates among general practitioners. Practitioners performing less than 10 abortions per year were less likely to provide medical abortion after 7 WG. Teleconsultation was widely used during the COVID-19 period and partially maintained after. Key motivations included offering women a choice of method and improving access by reducing delays. Among non-providers (n = 58), the main barriers were lack of demand (43%), fear of complications and insufficient training.

Discussion: The identification of eligible professionals revealed limited availability and visibility of private abortion providers in some areas. Midwives may represent an important driver for improving access to this practice. Targeted training and strengthened links with hospital services, particularly for low-volume providers or those expressing reluctance, may help improve its implementation.

Conclusion: Medical abortion between 7 and 9 WG is well accepted and widely practised in private primary care, with few practical challenges.

Corresponding author: Noémie Heyser, noemie.heyser@gmail.com

ID 2239- Pharmacists' perspective on dispensing contraception to high school students.

Morgane CHAMBOUX, Marion FOUQUET, Loïc DRUILHE

Médecine Générale, Tours, France

Context: The incidence of sexually transmitted infections (STIs) is increasing in Europe, particularly among adolescents. Their knowledge of STIs is poor and their sexual behavior is often risky. Several studies show that general practitioners are not recognized by high school students as the preferred point of contact for questions about sexuality, so there are few requests for consultations on this subject. Contraceptive provision is a frequent reason for adolescents to seek medical advice, but recent studies show that their main point of contact in this context is the dispensing pharmacist. Free condoms in pharmacies for 18–25-year-olds since

January 2023 reinforces the importance of pharmacists in matters of sexuality.

Objectives: The objective of this study was to explore pharmacists' perspectives on sexuality issues associated with dispensing contraception to high school students, as well as their professional exchanges with general practitioners on this subject.

Methods: This was a qualitative study using the grounded theory method conducted among a sample of community pharmacists based in the region XXX.

Results: Eleven pharmacists participated in semi-structured interviews between October 2024 and September 2025. They noted that they provided little information on sexuality issues when dispensing contraception to high school students. Some felt a lack of professional and personal legitimacy and even a fear of being ridiculous, when addressing these topics. They may resort to humor or a monotonous, trivialised discourse. Pharmacists also mentioned constraints related to the pharmacy, such as a lack of confidentiality or pressure from queues, which led them to sacrifice certain information, often relating to STIs and other sexuality issues. Although they found that people consider the pharmacy as : “an open bar”, they themselves felt isolated from other healthcare professionals.

Discussion: Pharmacists could be the key to identify the at-risk adolescents and referring them to the appropriate healthcare professional. However, to fulfill this role effectively, it is essential to improve their link with local care pathways.

Conclusion: A large-scale study is needed to assess the benefits of improving links between pharmacists and other local health professionals on high school students' knowledge and sexual health.

Corresponding author: Morgane Chamboux, morgane.chamboux@etu.univ-tours.fr

ID 1557- Endocrine disrupting chemicals and alterations in sperm parameters: an umbrella review

Dan EYAL

Paris-Cité, Paris, France

Context: Male infertility is an increasing public health concern. Numerous data suggest that environmental exposure to certain endocrine-disrupting chemicals (EDCs) may impair spermatogenesis. Among these, phthalates, bisphenols, triclosan, and parabens are ubiquitous compounds, widely used in plastics, food containers, and personal care products, that can interfere with hormonal regulation and induce testicular oxidative stress.

Objectives: To synthesize data from systematic reviews evaluating the association between postnatal exposure to these four classes of EDCs and alterations in sperm parameters in adult men.

Methods: An umbrella review (systematic review of systematic reviews) was conducted following PRISMA 2020 guidelines. PubMed and Embase were searched up to July 2025. Included were systematic reviews and meta-analyses focusing on adult men with postnatal biological measurements of exposure (urine, blood, or semen). Methodological quality was assessed using the AMSTAR-2 tool.

Results: Nine reviews published between 2015 and 2024 were included. A general adverse trend was observed between exposure to certain EDCs and sperm quality, particularly sperm concentration and motility.

Discussion: The level of evidence is moderate to high for phthalates, moderate for bisphenol A, low to moderate for triclosan, and low for parabens. Proposed mechanisms include testicular oxidative stress, hormonal disruption, and mitochondrial damage in germ cells.

Conclusion: This synthesis highlights a consistent body of evidence linking postnatal exposure to certain endocrine disruptors, notably phthalates and bisphenol A, with measurable impairment of sperm quality. While not demonstrating causality, these findings support the hypothesis of an environmental role in the decline of male fertility.

ID 836- Addressing Female Sexual Dysfunctions in General Practice: A Study of General Practitioners' Practices in Brittany

Alice EUDIER, Tiffany BONNET, Sidonie CHHOR

Université De Rennes, Rennes, France

Context: Female sexual dysfunctions are understudied despite an estimated prevalence of 50% among women. They are also rarely addressed during general practice consultations: only 8% of women are questioned about it, even though general practitioners (GPs) are their first point of contact.

Objectives: To study practices of GPs in Brittany in addressing and managing female sexual dysfunctions (FSD) and their potential barriers and expectations, in order to identify avenues for improvement.

Methods: A qualitative study, semi-structured interviews with general practitioners, either locums or established, practicing in Brittany.

Results: Thirteen physicians participated. Most reported feeling comfortable with the topic and acknowledged the importance of screening for FSD, although they underestimated its prevalence in their own patient population. Gynecological consultations were considered the most appropriate time to introduce the topic. Some presenting complaints, such as depressive disorders or chronic diseases, also prompted discussion. Physicians generally began management themselves before referring patients to other sexual-health professionals when necessary. The main barriers identified were lack of time, lack of solutions, as well as the patient's emotional and relationship context. Male physicians also cited their gender as a limitation.

Discussion: This study highlights that, consistent with literature, general practitioners tend to underestimate the prevalence of female sexual dysfunction and rarely address the topic during consultations, typically only when linked to the patient's primary reason for visiting. No literature-validated screening tools are employed. Key barriers identified include limited consultation time (as in the literature), inadequate training, discomfort related to the physician's gender, age-related assumptions about patients, cultural factors. Creating a dedicated sexual-health consultation, regardless of patient age, could help offset time limitations. Physicians expressed a need for brief, practical, literature-validated training programs focused on communication, alongside improved awareness among patients and partners. The study employs a rigorous qualitative methodology but presents limitations, including recruitment and a focus on heterosexual women.

Conclusion: The study shows that GPs seldom address female sexual dysfunctions outside gynecological consultations, hindered by time constraints and taboos. To facilitate the discussion of FSD a standardized question could be useful. It's important to improved professional training and increased patient awareness. Sexual health should be fully integrated into women's overall health.

Corresponding author: Alice Eudier, eudalice06@gmail.com

ID 592- Experiences and trajectories of thermal testicular contraception users : a qualitative study in metropolitan France

Matthieu PLANCHE [(1)] , Loup DUPIN [(2)], Sidonie CHHOR [(1)]

(1) Université De Rennes, Rennes, France
(2) Université De Tours, Tours, France

Context: The thermal testicular contraceptive method (TTCM) has been used since the 1980s and hasn't yet received marketing authorization. Initial clinical studies recommend wearing the device for 15 hours per day, with spermogram checks every three months to ensure temporary infertility. This approach has demonstrated significant contraceptive effectiveness. Several studies have explored both male and female expectations regarding TTCM, as well as the level of awareness among general practitioners.

Objectives: The objective of this thesis is to explore the experiences and trajectories of TTCM users in metropolitan France.

Methods: To address this research question, we conducted a qualitative study based on semi-structured interviews carried out between February and October 2024. Participants were men currently using, or who had previously used, a thermal contraceptive device, recruited through local user associations.

Results: Eleven participants were included. The interviews, which lasted an average of 60 minutes, revealed multiple motivations for starting contraception : concern for their partner's health, a desire to share the contraceptive burden, previous contraceptive failures, ecological considerations, and activist commitment. TTCM was chosen for being perceived as more respectful of the body, although some users remained cautious due to the limited number of clinical studies. User trajectories were often supported by two main networks : associative support, appreciated for its practical expertise, community engagement and assistance with device design, and medical support, which varied from informed encouragement to discouraging attitudes, that can lead to a breakdown in trust to the health care system. Contraceptive use was marked by experimental adaptation : adjusting the protocol to everyday life, managing spermograms, and navigating relationship dynamics. Participants expressed a strong desire for better recognition of the method by the healthcare system. TTCM represents a shift in gender roles, a way to take responsible action, and a challenge to traditional notions of masculinity.

Discussion: This study highlights key themes in the experiences of TTCM users and outlines areas for further research. Particular attention should be paid to users' expectations regarding medical follow-up by general practitioners and laboratories, the effects of male-led contraceptive experimentation on fertility, and the evolving paradigm of gender relations in this context.

ID 126- Impact of taking HIV pre-exposure prophylaxis on sexuality and mental well-being of users of this therapy.

Zoé BATAVE, Cyril PERROLLAZ

Médecine Générale, Montpellier, France

Context: PrEP is a prevention tool included in the global HIV strategy, aimed at reducing infection. Our research focused on its impact on the sexuality and mental well-being of its users.

Methods: We conducted a qualitative study using semi-structured interviews with adults taking PrEP for more than six months, followed at the CeGIDD (Institute for the Study of Sexuality and Disorders) in Montpellier. The phenomenological and thematic analysis aimed to explore their subjective experiences.

Originality: The originality of this study lies in its qualitative approach focused on the lived experience of PrEP users, beyond biomedical aspects. It highlights how PrEP transforms sexuality and psychological well-being, while revealing new ambivalences in HIV prev

Lessons learned and future implication: The interviews with the 11 participants highlight the profound transformations brought about by PrEP in terms of sexual and relational experiences. It is perceived as a lever of freedom, promoting a positive reinvestment in sexuality. The reduction in int

Discussion: The discussion explores how PrEP influences sexual behaviors, perceptions of risk, and users' mental health. It highlights psychological and sexual liberation, improved quality of life, but also raises questions about the decline in condom use, the relationship to medication, and generational differences in the perception of HIV.

Conclusion: Our study highlights the positive impacts of PrEP on sexuality and psychological well-being, while highlighting some ambivalence. A long-term, prospective quantitative study would allow for a more in-depth study of its impact on quality of life.

Corresponding author: Zoé Batave, zoe.batave@free.fr

ID 71- A brief tool to help general practitioners address adolescent sexual health in routine consultations

Camille LEPINE, Sarah MONGAULT

Dmg-Ft, Strasbourg, France

Context: Sexual health indicators among adolescents (rates of sexually transmitted infections, use of emergency contraception, and rates of abortion) highlight the need for general practitioners to address these issues during consultations. However, several barriers exist: lack of time, feelings of incompetence, discomfort with the topic, and the presence of parents. To date, no structured communication tool exists to facilitate such discussions during non-dedicated consultations.

Objectives: To develop a brief intervention tool for general practitioners, designed to initiate conversations about sexual health with adolescents, regardless of the initial reason for consultation.

Methods: A nominal group consensus method was used. A panel of 11 experts was recruited by email, selected for their experience in adolescent or sexual health (including established general practitioners, residents, a gynecologist, midwives, and a forensic physician). The nominal group session took place in February 2025 at the Faculty of Medicine, lasted three hours, and resulted in the creation of the tool. The session was audio-recorded twice and accompanied by note-taking by two researchers. After individual reflection, proposals were discussed collectively, organized into categories, prioritized, and reformulated by consensus.

Results: The proposed tool consists of seven questions or statements. It begins with a caring invitation that respects the adolescent's consent: "Now, if you're okay with it, we can talk a bit about your intimate life…" It includes wording adapted to the possible presence of parents and systematically reminds the patient of their right to medical confidentiality. The questions allow exploration of sexual activity and contraception needs. A closing phase standardizes the proposal of a dedicated follow-up appointment and the provision of reliable resources.

Discussion: The tool, developed by a multidisciplinary panel, is simple and quick to use. It is currently being evaluated among medical students and general practitioners regarding its feasibility, acceptability, and impact on professional practices.

Conclusion: We have created a brief intervention tool to be made available to general practitioners, enabling them to address sexual health with adolescents, regardless of the initial reason for consultation. The presentation of this tool provides an opportunity to reflect on professional practices, as well as on personal barriers and perceptions related to adolescent sexual health.

Ultrasounds

ID 1323- Training in focused clinical ultrasound for general practice: literature review and pedagogical model for GP residents in Lille

Victor VANDENBERGHE

Lille University, Hames Boucres, France

Context: In 2023, WONCA Europe was unequivocal : general practice requires reliable training in focused clinical ultrasound during residency. European primary-care ultrasound practices remain highly heterogeneous, and France lags behind in this field.

Objectives: To systematically review and synthesize the published literature regarding the education of general practitioners (GPs) and GPs in training (GPTs) in the use of ultrasonography with detailed information on modalities of teaching and assessing. Then, be able to suggest an ultrasound curriculum to general practice's residents.

Methods: This review was prospectively registered in PROSPERO, conducted according to the Cochrane recommendations and written following the PRISMA guidelines. We combined studies identified in a previous systematic review with studies from an updated literature search using a closer search string. Three reviewers independently screened

articles, and one extracted data. The search was conducted on June 23, 2024.

Results: Twenty papers were included. Ultrasound training was described to include both theoretical and practical training sessions. Major part of the population studied was GPs (65%). Nearly half of papers described a formation on a unique competence. 88,8% of them were about a cardio-vascular scan skill. Didactic lessons were quasi systematic (95%). 45% of studies used theoretical training by homework as videos or manuals. 100% of practical training included focussed hands-on training sessions under direct supervision, while 20% papers described additional longitudinal practical training under indirect supervision. Most of the time, the models were volunteer patients. Ultrasound exam was described to include self-assessment (50%) and/or hetero-assessement (80%), written (55%) and/or practical (80%). When it was a practical test, the major part (56,4%) consisted of a concordance test with experts.

Discussion: The strengths of this study are the updated international literature review on ultrasound training for general practitioners and the double screening for full texts. The main shortcoming of this study is the lack of article's exclusion on their quality.

Conclusion: There was a large variation in ultrasound training programs and assessments for GPs and GPTs. However, we had enough data in order to create a Point-Of-Care Ultrasound (POCUS) curriculum design for general practice's residency in XXX.

Corresponding author: Victor Vandenberghe, dr.vandenberghe.victor@gmail.com

ID 1210- Point-of-Care Ultrasound by the general practitioner : definition of a first level of competence by formalized consensus using the DELPHI method.

Murielle GLONDU-LASSIS [1], Mathieu BENGUIGUI [1], Jérôme CAMPAGNAC [1], Quentin FONTAINE [1], Eric JEZIORSKI [2], Laure FERRIERE [1]

(1) Université De Montpellier, Montpellier, France
(2) Chu Montpellier, Montpellier, France

Context: Point-of-Care Ultrasound (PCU), defined as "ultrasound performed in real time by the clinician at the patient's bedside," improves patient care, notably by reducing the time to diagnosis and initiation of treatment. PCU could also reduce inequalities in access to care in underserved areas. However, insufficient training and experience can have detrimental consequences for patients. In France, the training of future general practitioners (GPs) in PCU is underdeveloped. This training is therefore a major challenge for integrating this promising tool into GP practice.

Objectives: The objective of this study is to establish a consensus among GPs experienced in PCU regarding the relevant skills for an initial level of PCU competence for GPs.

Methods: We used the Delphi method. The rating group consisted of GPs and emergency physicians trained in PCU and practicing PCU regularly for more than two years. During the first round, experts rated and commented on 41 clinical skills assessments (CSAs). A second round was conducted using a questionnaire adapted to the results of the first round. Experts rated the CSAs that had not reached a consensus in the first round.

Results: Ten practitioners completed both rounds of the Delphi assessment. Of the 42 skills evaluated, 15 CSAs were deemed appropriate for a first level of competence for GPs, such as abdominopelvic skills, the search for deep vein thrombosis, and pleural and peritoneal effusions. The experts generally considered that tendon and ligament examinations could not be included at level 1 due to their complexity.

Discussion: This is the first study that establish an expert consensus on the qualitative composition of a first level of CSA skills in general practice using the Delphi method. Our results are consistent with those in the literature for skills covering various anatomical areas. The number of experts is in accordance with the recommendations of the French high authority for health for this type of methodology.

Conclusion: Our study identified skills that should enable the development of an initial training module for clinical skills assessment (CSA) for general practitioners or general practice residents. The training methods for each of the 15 selected skills need to be specified through further work.

Corresponding author: Murielle Glondu-Lassis, murielle.glondu-lassis@umontpellier.fr

ID 310- POCUS supported by tUS and AI - new horizons for family doctors.

Tomasz KARDACZ

Nzoz Im.l.rydygiera, Olsztyn, Pologne

Context: The increased availability of ultrasound machines allows for their increasingly widespread use in family physician practices. Basic knowledge of anatomy, medical education, and a keen eye for detail, combined with thoroughness and experience, allows for the inclusion of ultrasound examinations in a standard medical examination.

Methods: The author is a family physician with practices in a small town and a rural area. For decades, he has been observing the patient population under study, introducing numerous improvements to both clinics, such as computerization, telecommunications, rural rehabilitation, and POCUS ultrasound. He would like to share his experience with modern ultrasound technologies, particularly the use of TUS, multiscan, and the importance of AI programs for rapid POCUS diagnosis.

Originality: POCUS technology, based on tUS, multiscan, and AI, is one of the least popular yet extremely promising forms of family physician practice, especially in isolated populations with difficult access to diagnostics.

Lessons learned and future implication: In a world racing toward the future, it's not just technology that matters, but humanity and the fight for human dignity, quality of life, patient care, and equal access to diagnosis and treatment. POCUS, through its populist nature and universal access,

Discussion: Can the diagnostic process be completed in most cases during a family doctor's examination? Do we have to rely on confirmation of the diagnosis in specialized centers in most cases? What impact does the widespread introduction of POCUS have on treatment costs?

Conclusion: A revolutionary change is taking place in which the most sophisticated diagnostics appear in the hands of the most experienced primary care physicians.Whether we accept it or not, the world is changing and will continue to move forward. POCUS, tUS, multiscan and AI are a high-speed train that we may fear, but perhaps we should accept and embrace with all its benefits.

Corresponding author: Tomasz Kardacz, tomasz.kardacz@wp.pl

ID 583- Use of point-of-care ultrasound (POCUS) in French urgent primary care: a national survey of general practitioners in the SOS Médecins network

Boublay NAWALE

Université Claude Bernard Lyon 1, Lyon, France, Bron, France

Context: Point-of-care ultrasound (POCUS) is increasingly recognized as a valuable diagnostic tool in general practice. However, its actual use among French general practitioners (GPs) working in urgent care settings, such as SOS Médecins, a nationwide network of GPs providing home-based urgent primary care 24/7, remains poorly documented.

Objectives: To assess the prevalence, modalities of use, perceived impact, and barriers to the adoption of POCUS among GPs working in the SOS Médecins network across France.

Methods: A national cross-sectional online survey was distributed to all eligible SOS Médecins physicians. The questionnaire addressed POCUS usage, clinical indications, equipment access, perceived benefits, training needs, and adoption barriers. Descriptive statistics were used, and comparisons between users and non-users were performed using chi-square or Fisher’s exact tests.

Results: Among 211 respondents, 47.4 % reported current POCUS use. Age group (p = 0.0208) and years of SOS Médecins experience (p = 0.0034) differed significantly between users and non-users. The main indications were abdominal pain (79.2 %), vascular assessment (76.2 %) and respiratory symptoms (65.3 %). Most users relied on portable devices (69.8 %) and performed focused scans (87.4 %). POCUS was perceived as positively impacting triage (86.0 %), treatment decisions (81.7 %), diagnostic accuracy (67.0 %), autonomy (59.0 %) and the doctor–patient relationship (50.0 %). Only 15.6 % reported billing for POCUS. Among non-users, barriers included lack of training (63.6 %), limited time (44.5 %), equipment cost (40 %) and doubts about utility (23.6 %). Over half (54.5 %) expressed interest in training.

Discussion: POCUS use was frequently reported, with a prevalence close to that observed in high-adoption countries. Indications were consistent with international primary-care data. Interpretation must consider possible selection bias. Reported barriers mirror global findings and underline the need for structured training and organisational support.

Conclusion: With an adoption rate of 47.4% among respondents, this survey shows substantial POCUS use within SOS Médecins network, without reflecting national prevalence. Despite strong perceived usefulness, adoption remains limited by training gaps, organisational constraints during home visits, and unclear financial incentives. Strengthening undergraduate exposure, expanding structured continuing training, and clarifying reimbursement pathways may support broader and safer integration of POCUS in urgent primary care.

ID 408- 10 Binary Questions in General Practice – Ultrasound Answers

Philippe MARSAN

Cffe (centre Francophone De Formation En Échographie), Nïmes, France

Context: Ultrasound is becoming essential to confirm or ruling out a diagnosis in primary care medecine.With brief training and affordable devices, general practioners can acquire clinically relevant ultrasound skills that are usefull in their daily practice and consistent with evidence-based-medecine.(EBM).

Objectives: To demonstrate,through 10 concrete examples,the usefulness of ultrasound for general practioners in primary care practice.The ultrasound machine becaming the 21st century stethoscope.

Methods: We use the proven educational framework of EESF(école d'échographie sans frontière) and CFFE (centre francophone de formation en échographie) in Nïmes , training centers founded by professor J.M Bourgeois. We compare normal ultrasound images with pathological ultrasound images across several areas of interest for general practioners.We teach wich maneuvers should be performed to obtain this images.

Results: We aim to demonstrate,through imaging,the usefulness and speed of clinico-ultrasound maneuvers in ten specific situations. - musculoskeletal pathology : bone fracture ? supraspinatus tendon lesion ? - abdominal pathology : bladder volume ? hydronephrosis ? cholecystitis ? peritoneal effusion ? dilatation of the common bile duct ? - Thoracic pathology : pleural effusion ? - Vascular pathology : abdominal aortic aneurysm ? atheromatous plaques at the carotid bifurcations ?

Discussion: The ultrasound device provides the often-isolated general practitioner with valuable assistance in managing the most common diagnoses. Although training and cost may appear to be obstacles, opportunities for education within universities or through continuing professional development organisms, both in-person and online, are significant.

Conclusion: Ultrasound is becoming a decisive tool in primary care. By providing immediate answers to frequent clinical questions, it enhances diagnostic accuracy and patient safety. With accessible training and portable equipment, the general practitioner becomes a more efficient and autonomous clinician.

ID 157- Point-of-care ultrasound for assessing left ventricular ejection fraction

in heart failure of unselected patients in primary cares conditions: a systematic review

Perrine ALLIMANT, Isabellet Cibois-Honnorat

Department Of General Medicine, University Of Aix-Marseille, Marseille, France, Marseille, France

Context: Heart failure (HF) is the most frequent cardiovascular pathology in primary care. Echocardiography is its gold standard for diagnosis, follow-up and prognosis. Point-of-care ultrasound (POCUS) is of growing interest in daily practice.

Objectives: This study aimed to systematically review the literature to evaluate left ventricular ejection fraction (LVEF) assessment of unselected patients in primary cares conditions by non-expert physicians with cardiac POCUS (cPOCUS).

Methods: We searched in Medline, Embase and Pubmed up to January 2022 for interventional and non-interventional studies assessing LVEF with cPOCUS in unselected patients with suspected/diagnosed HF in hospital or outpatient settings, performed by non-expert physicians.

Results: Forty-one studies were included, involving 6432 patients, of whom 59.1% were outpatients. LVEF was assessed by 349 non-expert physicians after an initial ultrasound training course. The LVEF was mainly assessed by visual estimation (90.2%). The most frequent views were parasternal long/short axis, and apical 4-chamber. The median time of cPOCUS was 8 minutes. A strong agreement was found (Kappa = 0.75 [0.62 ; 0.83]) compared to experts when using different types of ultrasound devices (hand-held and standard), and agreement was excellent (Kappa = 0.84 [0.71 ; 0.89]) with the same device. Training course combined a median of 4.5 hours for theory and 25 cPOCUS for practice.

Discussion: This is the first systematic review specifically designed to evaluate the contribution of LVEF assessment in primary care conditions by non-expert physicians with cPOCUS in unselected patients with suspected or diagnosed HF. This study is strong (41 prospective studies, 6432 patients and 449 participants). Two independent reviewers analyzed strict inclusion criteria, study selection and data extraction. Nevertheless, lack of raw data, inhomogeneity and the large variations across studies limited our results. Finally, 75.6% of studies used hand-held US devices for non-experts compared to standard US devices for experts. Only one similar work was found from Gibson et al. published in June 2020. It tends towards the same conclusions.

Conclusion: The use of cPOCUS by non-expert practitioners after short training course appears to be an accurate complementary tool for LVEF assessment in daily practice. Its diffusion in primary care could optimize patient management, without replacing specialist.

Violences

ID 1935- Preventing Violence Against Patients in General Practice: A Collective Reflection by Young GPs

Mathilde CHOUQUET, Juliette GUARY, Marie BONNEAU, Antoine GIACOMINI

Reagjir, Rennes, France

Context: The trial of pediatric surgeon and child sex offender XXX, convicted of 299 assaults between 1989 and 2014, profoundly shook the XXX medical community. As young doctors, we were deeply affected by the extent of these acts. As members of the same association, we decided to work collectively to identify solutions at our level to better prevent violence against patients. We became aware of initiatives led in 2022 by the XXX Order of Physiotherapists, including the creation of a deontometer and evolutions in the management of reports of sexual violence. Strengths: experience sharing between young GPs, mutual support, progressive methodological improvement. Weaknesses: initial lack of formal methodology, discussions initially limited to young GPs, mainly remote meetings.

Methods: This collective developed through discussions and bibliographic work, resembling practice exchange groups. Research methods were progressively refined. Since June 2025, monthly videoconference meetings have brought together GPs from the same professional association, working in different areas. Complementary

interviews with other stakeholders were also conducted.

Originality: The group was formed in response to the XXX affair to allow discussion of this difficult subject and its broader implications. Violence against patients was explored from multiple perspectives. One major objective became the development of a GP-adapted de

Lessons learned and future implication: This group provided a space to share a challenging experience and fostered empowerment through collective work. Earlier methodological support would have improved structure and efficiency; however, this flexible organization enabled rapid mutual support a

Discussion: Discussing violence against patients is essential for GPs, both to improve patient care and support practitioners, because working conditions can be at risk of violence. The deontometer may facilitate dialogue with institutions. WONCA will offer an opportunity to exchange internationally on this topic.

Conclusion: This collective reflection strengthened our confidence, improved our practices, and motivated us to pursue this work through a more structured research approach focused on creating a tool for prevention.

ID 963- Perceptions of Violence Among Men: A Qualitative Study and Implications for Primary Care

Florence ADELINE-DUFLOT, Matthieu HACQUES, Pierre LE DOUARON

Département De Médecine Générale Université De Rennes, Rennes, France

Context: The 2019 Living Environment and Security survey estimated an average of 1,101,000 victims annually, of whom 46% identify as male. Most screening tools in primary care remain gendered. Experienced violence has significant health consequences, and individuals identifying as male often encounter barriers when seeking assistance.

Objectives: This aim of this study was to explore perceptions of violence among individuals identifying as male to inform strategies for addressing this issue in general practice consultations

Methods: A qualitative study was conducted using semi-structured interviews with adult participants self-identifying as male, between May 2023 and February 2025. Data analysis was guided by principles of grounded theory.

Results: Eleven interviews were conducted with men aged between 22 and 76 years. Violence was perceived as a universal experience with emotional, cognitive, and behavioral repercussions. Perceptions appeared shaped by societal norms and expectations of masculinity, which acted as barriers to recognizing victimhood and seeking external support.

Discussion: The experience of violence subsequently gives rise to strategies comparable to coping mechanisms. The principal strength of this study lies in the fact that it was conducted outside medical practices. However, young adults were underrepresented in our sample. To facilitate its integration into general practice consultations, we propose a model inspired by DiClemente and Prochaska's stages of change.

Conclusion: This study underscores the complexity of representations of experienced violence among individuals identifying as male. A motivational interviewing approach, combined with a critical examination of hegemonic gender norms, may open new avenues for support and intervention in primary care settings.

ID 693- Identifying clinical signs of child abuse in primary care : a systematic review

Nolwenn VAN DER WINDT, Naïs CORSI

Université Clermont Auvergne, Clermont Ferrand, France

Context: Child abuse is responsible for clinical signs that are often little known, leading to an

underestimation of violence. One billion children worldwide are victims of violence according to UN agencies.

Objectives: The objective of this study is to identify the clinical signs of abused children consulting in primary care.

Methods: A systematic review was conducted in the PubMed, Cochrane, PsycInfo, Embase, and Cinahl databases from 1996 to January 2024. The studies included focused on children aged 0 to 18 who were victims of abuse and consulting in primary care.

Results: Of the 3,811 articles found in the databases, 19 were included in the review. Signs of physical trauma included fractures, bruises, burns, genital and neurological injuries. Somatic symptoms in children may include abdominal pain, persistent non-specific symptoms, and atopic manifestations such as eczema or asthma. The psychological symptoms identified were depression, despair, and anxiety. Abuse is also associated with behavioral disorders (externalizing or internalizing behaviors) and developmental delays (language, learning, and social interaction disorders).

Discussion: Child abuse can appear in many different ways. That is why it is hard to identify in primary care. The studies included have limits: small and varied samples, different definitions of primary care. Many relied on self-reported data and some lacked complete information, which also reduced precision. Despite this, the results are consistent with previous publications showing links between abuse and physical injuries, psychological symptoms, somatic complaints, or developmental delays. Primary care remains a crucial place to detect these situations early, but practitioners may struggle with doubts, emotional discomfort, and unfamiliarity with reporting procedures. More training and support would help them feel better equipped to act.

Conclusion: There are few articles studying the clinical signs of child victims of violence consulting in primary care. These children may present with various clinical signs (physical trauma, pain, atopy, psychological disorders, behavioral disorders, developmental delays) that highlight the importance of considering abuse.

Corresponding author: Nolwenn Van Der Windt, nolwenn.vanderwindt@wanadoo.fr

ID 630- Evaluation of a university training program on the management of intimate partner Violence: a mixed-methods pilot study in XXX

Jean-Baptiste PECASTAING [(1)] , Clélia BONDY [(2)], Maeliss HAMON [(2)], Vikie HERMANT [(2)], Mathieu DOMBLIDES [(1)], Racha ONAISI [(1)], Théodore WOLF [(1)], Laura BELAIDI [(2)], Maite SANTUCCI [(2)]

(1) Département Universitaire De Médecine Générale-Collège Des Sciences De La Santé Université De Bordeaux, Bordeaux, France
(2) Collège Des Sciences De La Santé Université De Bordeaux, Bordeaux, France

Context: Intimate partner violence (IPV) has major medical, social, and economic consequences. General practitioners, often the first point of contact for victims, frequently report insufficient training. In 2022, a dedicated IPV training program was implemented at the University of XXX for general practice residents. Based on Dr. XXX work, it comprised four modules: screening and identification of violence, support and follow-up of victims, emergency situations, and long-term management.

Objectives: To assess the impact of this training on the development of clinical competencies among general practice residents and to explore how these competencies are mobilized in simulated scenarios.

Methods: This mixed-methods pilot study combined Objective Structured Clinical Examinations (OSCEs) and semi-structured interviews. Four OSCE stations specifically designed for the study and performed with trained actors assessed IPV-related clinical competencies. Standardized checklists enabled quantitative analysis using Student's t-test. Semi-structured explicitation interviews, following an inductive phenomenological approach, were conducted immediately after the OSCEs to complement quantitative findings. Data collection occurred over a single day. Performance of 11 residents was compared according to participation in the training program.

Results: Trained residents achieved higher overall scores. Significant differences were observed in the "screening" and "emergency" stations, as well as in cognitive, reflective, and psycho-affective domains. Interviews highlighted improvements in understanding the mechanisms of IPV, managing complex care situations, use of available support networks, emotional regulation, and more structured clinical reasoning.

Discussion: This study suggests that the training reinforces residents' competencies beyond theoretical knowledge. Although the small sample size is a limitation, the significant findings and the use of a mixed-methods design (OSCEs and interviews) strengthen the study. This approach appears relevant for evaluating educational impact. Areas for improvement include fostering empathy and integrating routine OSCE assessments.

Conclusion: The training program appears to enhance practical and reflective competencies in simulated scenarios. Broader implementation and long-term evaluation seem warranted to improve care for IPV victims.

Corresponding author: Jean-Baptiste Pecastaing, drpecastaingjba@gmail.com

ID 584- Doctors' comfort in addressing domestic violence: the effect of training.

Jessica GUELFF [(1)] , Amandine ANDRÉ [(2)], Lucie CHAUVIN [(2)]

(1) Univ Angers, Pops, Sfr Icat, F-49000 Angers, France, Angers, France
(2) Univ Angers, 49 000 Angers, France, Angers, France

Context: Doctors are often the first point of contact for victims of domestic violence. They play a key role in identifying and reporting cases. In France, the law of 30 July 2020 relaxed the conditions for lifting medical confidentiality in cases of immediate danger and abuse of power. In 2024, all practising doctors in XXXX department received a booklet on reporting domestic violence, followed by face-to-face training.

Objectives: This study aims to assess the effect of this training on the level of comfort of doctors in the XXXX department in dealing with these situations.

Methods: A descriptive and comparative study was conducted using two online questionnaires mailed to all practising doctors in XXXX department before (T0) and four months after (T1) the training. The doctors self-assessed their comfort level on eight key dimensions (identification, reporting, support, legal aspects) using a scale of 1 to 4. The variables were analysed descriptively, then the mean scores were compared according to whether or not the doctors had participated in the training, using Student's t-tests.

Results: 118 responses were collected at T0 and 84 at T1, including 29 trained doctors. The latter showed significantly greater ease (mean = 2.84) than non-participants (mean = 2.22; $p < 0.001$), particularly with regard to lifting medical confidentiality, assessing danger, writing and sending the report, and post-report support. No significant difference was observed in assessing control or engaging in dialogue. At T1, in a real reporting situation, no significant difference was found between those who had participated in the training and others.

Discussion: In addition to an information booklet, targeted training significantly improved doctors' reported comfort with the technical and legal aspects of domestic violence. Its widespread use, accompanied by simulation exercises to develop 'action' skills, could improve the management of these situations in the long term. Research on a larger sample size could provide a more robust assessment of the real-life impact of this type of training.

Conclusion: The level of comfort in reporting domestic violence improves following specific training. A wider range of training methods is needed in order to achieve a real-life effect.

ID 457- Gender-based and Sexual Violence and Mental Health among French University Students: A Cohort Study

Rodeline TELFILS

Univ Rouen Normandie, Inserm, Normandie Univ, Aden Umr1073, Nutrition, Inflammation Et Axe Microbiote-Intestin-Cerveau,, Rouen, France

Context: Sexual and gender-based victimization (SGBV) is a major public health issue in higher education and can have lasting effects on students' mental health

Objectives: This study aimed to identify victimization trajectories and assess how repeated exposure influences mental health and risk behaviors.

Methods: A prospective e-cohort was launched in October 2024 at XXX, with follow-up every three months among 563 students aged 18–30 years. Students who completed the M0, M3, and M6 assessments were included. Sexual and gender-based victimisation was measured at each wave and used to classify participants into five trajectories: non-victim, one-timer (a single incident reported at one timepoint), Multiple(more than one incident reported at a single timepoint), Chronic (a single incident reported at more than one timepoint) and chronic-multiple(victimisation reported at more than one timepoint, with multiple incidents at least once).Mental health and behavioural outcomes included depressive symptoms (CES-D8), anxiety symptoms (Hamilton scale), insomnia (Insomnia Severity Index), suicide attempts, disordered eating behaviours, and tobacco use. Victimisation prevalence was calculated at each timepoint, and outcomes were compared across the five trajectories using ANOVA or Chi-square tests, as appropriate.

Results: At M0, 51.7% of students reported at least one victimisation since the beginning of their studies, while 35.5% reported victimisation in the past 3 months at M3 and 31.6% at M6. Between M0 and M6, 7% were one-timer victims, 17% multiple victims, and 37% experienced chronic-multiple victimisation.Students with chronic-multiple victimisation displayed markedly worse mental health outcomes, including higher depressive symptoms (11.6 vs 5.0, $p<0.001$), anxiety symptoms (21 vs 7, $p<0.001$), and insomnia severity (13 vs 5, $p<0.001$).Risk behaviours also increased sharply with exposure severity, including disordered eating (68.6% vs 38.4%), suicide attempts (14.3% vs 3.6%), and tobacco use (28.5% vs 16.5%) (all $p<0.001$).

Discussion: Chronic and multiple victimization is associated with an increased risk of depression, anxiety, insomnia, and suicide. Primary care physicians should routinely consider sexual and gender-based violence when assessing young adults with symptoms of mental health disorders and provide early trauma-informed support.

Conclusion: Addressing SGBV is essential to protecting student privacy, promoting equal access to mental health care, and strengthening community in higher education settings.

ID 35- Aborder les mutilations génitales féminines en médecine générale : comment en parler en consultation ?

Ilayda SERIMÖZÜ [(1)] , Fabienne RICHARD [(2)], Manon DE MONTIGNY [(1)]

(1) Université Catholique De Louvain, Brussels, Belgique
(2) Université Libre De Bruxelles, Brussels, Belgique

Context: Female genital mutilation (FGM) involves the partial or total removal of the external female genitalia or other injury for non-medical reasons. Worldwide, more than 230 million women and girls have undergone FGM, with millions more at risk each year. In Europe, the number of women and girls affected or at risk is increasing due to migration from countries with high prevalence rates. In this multicultural context, general practitioners (GPs) play a key role in prevention, detection, and care, yet many report discomfort or hesitation in addressing the issue with patients.

Objectives: This study aimed to explore the barriers and facilitators experienced by GPs when discussing FGM in primary care and to identify practical, culturally sensitive communication strategies to improve prevention and holistic care.

Methods: A qualitative study was conducted through two focus groups involving seven GPs with experience caring for patients affected by FGM. Discussions were recorded, transcribed, anonymised, and thematically analysed to identify key challenges, attitudes, and best practices.

Results: Participants highlighted the importance of contextualising the topic, maintaining a professional, empathetic and non-judgmental attitude, and adapting communication to the patient's background. They reported limited training on FGM, uncertainty in identifying its types, and a lack of referral pathways. The need for clearer guidelines, visual aids, and structured communication tools was emphasised to support effective prevention and patient-centred care.

Discussion: FGM is perceived by GPs as a complex and culturally embedded issue requiring a holistic, person-centred approach. Open, respectful dialogue is essential to build trust and overcome taboos. Improved medical education, practical consultation tools, and multidisciplinary collaboration could enhance GPs' confidence and competence in addressing FGM.

Conclusion: Training, cultural sensitivity, and communication tools are crucial to empower GPs to engage effectively in FGM prevention and care. Strengthening awareness and integrating FGM-related content into professional curricula would contribute to safer, more inclusive, and patient-centred primary care. Keywords: General Practice, Female Genital Mutilation, Cultural Competency, Communication

Wait… Did you say weight again?

ID 1683- Analysis of the implementation of an intersectoral learning community for obese individuals in rural areas: a participant observation study

Geraldine LAYANI [1] , Blandine LENTILHAC [2], Audrey L'ESPÉRANCE [3], Nadia SOURIAL [1], Anne SCHWEITZER [4], Laurence BERTHELET [5], Micheline THÉRIAULT [1]

(1) Université De Montréal, Montréal, Canada
(2) Chum, Montréal, Canada
(3) Ecole Nationale D'administration Publique, Montréal, Canada
(4) Université Du Québec En Outaouais, Gatineau, Canada
(5) Cisss Chaudière-Appalaches, Lévis, Canada

Context: Obesity is a complex health issue that affects nearly 30% of XXX. Beyond its clinical definition, people living with obesity (PLWO) face persistent social and structural barriers that negatively impact their well-being. Given that healthcare influences only about 20% of health outcomes, interventions must prioritize partnerships beyond the healthcare system. In this context, a participatory research initiative was launched, led by a citizen and a researcher, to co-create the first intersectoral learning community for, with, and by PLWO in a rural region of XXX.

Objectives: To analyze the impacts of partnership-based action during co-design workshops aimed at jointly developing an intersectoral learning community.

Methods: From March to November 2025, four co-design workshops (three in person, one online) were conducted with 22 participants from health, community, and municipal sectors, alongside PLWO. A participatory qualitative design using participant-observation examined interaction and collaboration dynamics. Bilodeau's model of six conditions for successful intersectoral action guided the analytical framework. Data collection included structured observation grids, field notes, and audio recordings. Thematic coding was performed using NVivo with a deductive, triangulated analysis approach.

Results: Workshops demonstrated strong engagement and evolving collaborative dynamics. PLWO initiated most discussions and displayed significant leadership. Exchanges shifted from general reflections to context-specific solutions. Online participation generated less engagement, highlighting the importance of in-person interaction. The use of persona-based facilitation grounded discussions in lived experience and stimulated creative, solution-oriented dialogue. Tangible emerging collaborations, particularly between health and community sectors, were observed. Participants mapped existing local initiatives and developed new partnerships beyond workshop sessions, revealing both the potential and the fragility of sustained engagement in rural contexts.

Discussion: Limitations relate to implementation in a rural region where stakeholders are already involved in multiple projects, which may influence engagement. The study highlights the strengths of flexible facilitation and methods tailored to diverse

stakeholders, fostering shared understanding and helping bridge sectoral boundaries.

Conclusion: This study illustrates how structured participatory approaches can strengthen person-centred, equitable, and integrated care for PLWO. The model offers transferable lessons for intersectoral initiatives seeking to embed co-design with people with lived experience and address other complex health issues requiring cross-sector collaboration.

Corresponding author: Blandine Lentilhac, blandine.lentilhac@umontreal.ca

ID 1684- Intersectoral interventions for people living with obesity: an environmental scan.

Geraldine LAYANI [(1)] , Anne SCHWEITZER [(2)], Blandine LENTILHAC [(3)], Marielle YAPI [(3)], Thameya BALASINGAM [(1)], Jean-Baptiste GARTNER [(4)], Nadia SOURIAL [(1)], Laurence BERTHELET [(5)]

(1) Université De Montréal, Montréal, Canada
(2) Université Du Québec En Outaouais, Gatineau, Canada
(3) Chum, Montréal, Canada
(4) Université Laval, Montréal, Canada
(5) Cisss Ca, Lévis, Canada

Context: Obesity is a major global health challenge influenced by genetic, behavioral, socioeconomic, and environmental factors. Although healthcare influences only 20% of health outcomes, most interventions still focus on weight rather than broader social determinants of health (SDH). Addressing obesity effectively requires intersectoral approaches bridging health, social, community, and policy domains. Launched in 2023 by a citizen partner and a clinical researcher, the XXX participatory research initiative aims to co-develop an intersectoral learning community for, with, and by PLWO to better meet their needs. Given limited data on intersectoral engagement, a preliminary environmental scan was conducted.

Objectives: To identify and characterize intersectoral interventions targeting PLWO in community and primary care settings

Methods: Following Arksey and O'Malley's framework, a comprehensive search was conducted across three academic databases and grey literature sources (May 2024-February 2025). Eligible records described intersectoral interventions for adults in XXX countries (since 2006, English or French). Data extraction followed an adapted conceptual framework based on SDH and was synthesized according to PRISMA 2020. Bibliometric mapping using VOSviewer® refined the conceptual mapping.

Results: 23 of 6876 studies (20 peer-reviewed, 3 grey literature), mainly from the United States and focused on lifestyle modification programs. Obesity was primarily defined using weight-based metrics with little consideration for SDH. None explicitly defined intersectorality. Collaborations mainly involved health, academic, community, and faith-based sectors, with community health workers emerging as essential connectors between clinical and social domains. Outcome measures remained largely biomedical, with minimal integration of SDH indicators. The results highlight the need to integrate social determinants of health into evaluation frameworks, formalize intersectoral governance, and institutionalize community health workers to promote equity and person-centered care.

Discussion: This first environmental scan on intersectoral interventions for PLWO provides new insights into how collaborative approaches are designed, implemented, and evaluated. While the focus on high-income countries and English/French sources may have limited cultural diversity, including grey literature, strengthened contextual understanding. The strength of this study lies in the bibliometric analysis, which reinforces the qualitative data extracted.

Conclusion: These insights will guide the XXX learning community in developing co-creation workshops that promote integrated, sustainable intersectoral strategies for obesity management

(6) National Society Of Medical Education In General Practice (snamid), Caserta, Italie
(7) Family Medicine, Izmir University Of Economics, Izmir, Türkiye
(8) Federica Montseny Healthcare Center, Unidad De Investigación, Gerencia Asistencial De Atención Primaria,, Madrid, Espagne
(9) Investigation Support Multidisciplinary Unit For Primary Care And Community North Area Of Madrid, Madrid, Espagne

Context: Obesity remains a significant public health challenge in Europe, affecting both adults and children and adding pressure on primary health care (PHC) systems. Although behavioural, nutritional, digital, and pharmacological interventions are available, their integration into routine PHC is uneven. Persistent gaps between guidelines and practice underscore the need to understand the real-world barriers and facilitators shaping obesity care delivery.

Objectives: This scoping review aims to identify key factors that hinder or support the implementation of obesity management interventions in PHC and to inform practical strategies, training needs, and system-level supports for more effective, person-centred obesity care.

Methods: The review is being conducted according to PRISMA-ScR guidelines and PICOS-based criteria. Searches were carried out across PubMed (n=206), Web of Science (n=386), Scopus (n=212), ScienceDirect (n=192), and the Cochrane Library (n=92), covering publications from 2019–2025 in seven languages. After removing 422 duplicates, 665 records underwent title and abstract screening, with 293 excluded. In total, 372 full-text articles were sought for retrieval and are currently under assessment. Eligible studies include adults or children with overweight or obesity in PHC and address lifestyle, behavioural, nutritional, pharmacological, digital, or system-level interventions. Grey literature, theses, and policy reports were included to ensure comprehensive coverage. The protocol is registered with the Open Science Framework.

Results: Preliminary findings point to several recurring challenges: regulatory and financial barriers to pharmacological treatments; limited time and resources in consultations; insufficient training for PHC teams; and the persistent role of stigma in shaping communication and patient engagement. Facilitators include structured clinical pathways, multidisciplinary teamwork, adoption of person-first language, and increasing use of digital tools to support follow-up and self-management. PHC professionals consistently emerge as central coordinators of long-term obesity care.

Discussion: Early evidence shows that barriers span patient, provider, and system levels, indicating a need for better alignment between policy commitments, clinical guidance, and day-to-day PHC operations. Strengthening training, organisational support, and access to treatments may enhance intervention uptake and fidelity.

Conclusion: This review will synthesise current evidence to guide the development of actionable and scalable strategies that reinforce obesity management in PHC and support more equitable, person-centred, and sustainable obesity care across Europe

Corresponding author: Raquel Gómez Bravo, raquelgomezbravo@gmail.com

ID 1065- Structured weight-loss programmes in primary care and their impact on HbA1c among adults with prediabetes: a systematic review

Serge ENGAMBA, Ayokunle OSONUGA

Exeter University, Exeter, Royaume-Uni

Context: Prediabetes is a growing global challenge, with most cases diagnosed and managed in primary care. Lifestyle modification—particularly weight reduction—is central to delaying or preventing

progression to type 2 diabetes, yet the specific impact of structured weight-loss programmes on HbA1c within primary care remains unclear. Understanding their effectiveness is essential to inform evidence-based prevention strategies in general practice.

Objectives: To synthesise current evidence on the effectiveness of structured weight-loss programmes delivered or initiated in primary care on HbA1c reduction in adults with prediabetes, and to identify features associated with greater clinical benefit.

Methods: A systematic review was conducted using PRISMA 2020 and SWiM guidelines. Six databases (MEDLINE, EMBASE, CENTRAL, Scopus, CINAHL, Web of Science) were searched to July 2025. Eligible studies included adults (≥18 years) with prediabetes enrolled in structured weight-loss programmes implemented in primary care. Randomised controlled trials, cohort studies, and pilot interventions were included. The primary outcome was change in HbA1c. Risk of bias was assessed using RoB-2 and ROBINS-I. Heterogeneity precluded meta-analysis; findings were synthesised narratively.

Results: Seven studies (sample sizes 43–2227) from diverse high-income settings met inclusion criteria. All interventions were associated with HbA1c reductions ranging from −0.03% to −0.83%. High-intensity behavioural programmes and digital interventions demonstrated the largest improvements. Weight loss (up to 7.2 kg), reductions in BMI, and favourable changes in lipid profiles were commonly reported secondary outcomes. Adherence consistently mediated HbA1c outcomes, with completers achieving greater benefit. However, reporting of adherence, intervention fidelity, and long-term follow-up was inconsistent across studies.

Discussion: Structured weight-loss programmes in primary care consistently support glycaemic improvement in prediabetes. Digital delivery models and higher-intensity behavioural programmes may enhance accessibility and impact, though variations in programme structure, population characteristics, and engagement complicate comparisons. The evidence base remains limited by heterogeneity, modest sample sizes in some studies, and lack of diverse or underserved populations.

Conclusion: Structured weight-loss interventions delivered in primary care contribute to modest but clinically meaningful reductions in HbA1c. Integrated digital or higher-intensity behavioural approaches hold particular promise. Future research should prioritise standardised reporting, equity-focused design, and long-term outcomes to guide scalable prediabetes management in general practice.

ID 666- Approach to the psychosocial determinants of overweight by general practitioners

Jessica GUELFF [1] , Nihal ALI-MOHAMMED [2]

(1) Univ Angers, Pops, Sfr Icat, F-49000 Angers, France, Angers, France
(2) Univ Angers, 49000 Angers, France, Angers, France

Context: Overweight and obesity increase morbidity and mortality. In 2022, 43% of adults worldwide were overweight. In the XXXX region, this prevalence is on the rise. The causes of overweight are multifactorial, with significant psychosocial determinants, and there is a need for a comprehensive public prevention policy. The Haute Autorité de Santé (HAS) identifies general practitioners as the first point of contact in the management of excess weight.

Objectives: Study the approach to socio-economic and psychological determinants in the management of adult overweight by general practitioners practising in the region XXXX.

Methods: A quantitative descriptive and analytical cross-sectional study was conducted among private general practitioners in the XXX region, using an anonymous questionnaire emailed in October 2024. The main criterion was the approach to all the psychosocial criteria proposed according to the literature. The variables were analysed descriptively, and comparisons were then made between groups offering consultations dedicated to overweight and those that did not.

Results: 195 responses were analysed. Only 12.3% of doctors addressed all psychosocial determinants 'often' or 'always'. This rate reached 21.5% among doctors conducting dedicated consultations, suggesting that care remained partial despite the specific time allocated. Participants were aware of the importance of psychosocial factors in overweight, but remained focused mainly on health and dietary rules.

Discussion: The study reveals that the approach to overweight remains predominantly biomedical despite a declared awareness of the importance of psychosocial determinants. These determinants are addressed more frequently when doctors have specific consultations on overweight. These results highlight the value of adapting medical practices by promoting a motivational, multidisciplinary and collaborative approach. A better understanding of negative perceptions and barriers to a comprehensive approach to overweight is needed to improve the quality of care and promote more comprehensive management tailored to patients' needs.

Conclusion: Despite awareness of the importance of psychosocial factors, doctors report an approach that is primarily biomedical and focused on health and dietary rules. Having a dedicated consultation improves overall care. A motivational, multidisciplinary approach and an ambitious public prevention policy are desirable, as the issues surrounding overweight cannot be reduced to the prism of health.

ID 1723- Microeconomic study of the mobile effect of permanent outpatient care in the XXX department of XXX in 2024.

Pierre-Jean BAUDOT [(1)] , Anne CATHALIFAUD [(2)]

(1) Faculty Of Medicine, Limoges, France
(2) General Practitioner, Limoges, France

Context: The continuity of outpatient care (PDSA) refers to the organisation of outpatient care outside normal medical practice opening hours. Improving this service is a public health issue that must guarantee all citizens access to effective PDSA while controlling costs for society. Its operational balance depends on the voluntary participation of doctors. XXX is something of an exception in XXX, with mobile services continuing throughout the night. This study examines the financial aspects of mobile services.

Objectives: The primary objective was to compare the cost of mobile care with the cost of referral to hospital emergency departments. In the absence of mobile care, patients would be assessed in emergency departments by default. The secondary objective was to estimate the number of emergency department visits avoided.

Methods: Microeconomic study in XXX in 2024. Calculation of the cost of PDSA mobile care, the cost of medical transport and a visit to the emergency room.

Results: The mobile PDSA service in 2024 cost approximately €1,580,959.60 for those insured by the Primary Health Insurance Fund in XXX. In comparison, referring all affected patients to hospital emergency services was estimated to cost €2,429,796.32. The PDSA mobile service in XXX in 2024 enabled 5,576 patients to remain at home, thereby avoiding the same number of visits to the emergency department.

Discussion: PDSA's mobile service cost €834,078.32 less than ambulance transport and emergency room visits. This represents 15.2 visits avoided per day

Conclusion: The current operation of the PDSA in XXX provides comprehensive coverage of the territory outside normal medical practice opening hours. It enables an effective response to urgent visits, as well as requests for death certificates and administrative certificates. It provides a high level of medical service to the population, enabling the most vulnerable to avoid harmful medical transport. It places greater professional demands on doctors.

ID 2184- Social media and the image of general practitioners: a qualitative study of patients' and physicians' perspectives

Abdelkader LAHMAR, Caroline LAUER

University Of Strasbourg, Strasbourg, France

Context: Social media use has expanded rapidly in healthcare, involving both patients and physicians. Beyond information sharing, these platforms shape the public image of doctors and may influence professionalism and the patient–doctor relationship in primary care. However, their impact on the perceived image of general practitioners remains insufficiently explored, particularly from a combined patient and physician perspective.

Objectives: The primary objective of this study was to explore how the image of general practitioners on social media is perceived by both physicians and patients. We aimed to analyse patterns of use, perceived benefits and risks, and implications for professionalism and the patient–doctor relationship in primary care.

Methods: We conducted a qualitative study between October 2024 and March 2025. Using iterative theoretically reasoned sampling, ten participants were recruited: five general practitioners and five patients. Data were collected through semi-structured individual interviews. A qualitative analysis inspired by grounded theory was performed, allowing themes to emerge inductively through iterative coding and comparison of physicians' and patients' perspectives.

Results: Both physicians and patients reported frequent personal use of social media, while professional use among general practitioners was heterogeneous. Social media were perceived as tools for health education, professional networking, and public health communication. Physicians expressed strong concerns regarding professional image, confidentiality, and boundary management between private and professional spheres, often adopting self-regulation strategies. Patients generally viewed physicians' presence on social media positively when focused on educational content. However, ambivalence emerged toward highly visible "content-creator" physicians, with concerns about credibility, commercial interests, oversimplification of information, and potential trivialisation of medical expertise. Both groups highlighted risks related to misinformation, insufficient identification of professionals, and lack of clear professional regulation.

Discussion: Social media represent an ambivalent space for primary care, simultaneously supporting patient education, visibility of the medical profession, and patient engagement, while exposing physicians to ethical, professional, and relational challenges that may affect trust.

Conclusion: Social media use influences the image of general practitioners and contributes to reshaping the patient–doctor relationship in primary care. These findings highlight the need for clearer professional guidance and training in digital professionalism to promote ethical, trustworthy, and patient-centred use of social media.

ID 1857- From gross medical density to active force: characterizing territorial vulnerabilities in general medicine

Charlotte DE FONTGALLAND [(1)], Katerina KONONOVICH [(2)] , Jean-Marc MACÉ [(2)], Frédérique MÉNORET [(3)]

(1) Urps Ml, Orléans, France
(2) Lirsa-Cnam, Paris, France
(3) Assurance Maladie, Orléans, France

Context: Numerous studies have examined the uneven distribution of doctors across the country and the impact of public policy on variations in healthcare provision. However, few studies investigate the specific characteristics of general practitioners and their impact on healthcare provision.

Objectives: This study, conducted by the URPS-ML and the Centre-Val-de-Loire Health Insurance Fund, aims to develop a methodology for identifying general practitioners among the omnipraticiens listed in the SNIIRAM database and to identify the actual activity of general practitioners.

Methods: Analysis of general practitioners' activity data (SNIIRAM and ERASME) allows us to determine

variables that identify general practitioners according to the criteria of the Collège de Médecine Générale (general practitioner fees, G or CCAM-rated procedures, etc.). To convert their activity into a more relevant indicator than "gross medical density," the number of procedures constituting "synthetic activity" in a given territory is calculated using two indicators: the first, called "active workforce," combines the workforce measured by the "weighted activity coefficient" of each professional, while the second, called "effective medical density," corresponds to individuals weighted by the "active workforce." These results were confirmed by qualitative work with a statistically robust sample of physicians.

Results: In the Centre-Val-de-Loire region, 1,731 doctors are registered as omnipraticiens. Only 1,531 are identified as general practitioners, representing a workforce of 1,577 doctors (active workforce). This represents an 8.8% drop between the supposed and actual supply of healthcare in a region with the lowest density of general practitioners in France.

Discussion: This work highlights additional weaknesses: in one territory, 24 doctors have an "active workforce" equivalent to 35.8 doctors, which is a 33% underestimation of the actual density, raising questions about the long-term sustainability of their activity and the number of doctors needed to replace them after they retire. Conversely, some areas have a lower active workforce than the actual density of the area, due to practice choices.

Conclusion: This study made it possible to accurately characterize the primary care provision in the Centre-Val-de-Loire region and to propose a conventional doctor zoning based on the actual provision of care, as close as possible to the field and the difficulties faced by professionals and patients.

Corresponding author: Katerina Kononovich, katerina.kononovich@gmail.com

ID 1399- Negotiating Professional Identity: The lived experience of doctors with visible disabilities in the French medical system.

Alexandra HELLIO [(1)] , Nelly AZAIEZ [(2)]

(1) Département De Médecine Générale Sorbonne Université, Paris, France
(2) Unité D'informations Et De Soins Des Sourds, Uniss. Assistance Publique, Hôpitaux De Paris. Hopital Pitié Salpêtrière, Paris, France

Context: In the medical imagination, the doctor is traditionally perceived as the one who heals, not as the one who embodies vulnerability.Twenty years after the enactment of the French law on equal rights and opportunities (11 February 2005), the lack of official data on doctors with disabilities reflects a persistent invisibility of this reality within the medical profession. Far from being a purely individual issue, the situation of doctors with disabilities raises questions about the ability of the health system to fully integrate the diversity of professionals.

Objectives: This paper explores how physicians with visible disabilities construct and negotiate their professional identity within a health care system that is predominantly structured by normative and ableist norms.

Methods: This is a qualitative phenomenological study based on semi-structured interviews with 17 doctors in France with different visible disabilities (motor, sensory, dermatological). The sample was diversified by age, specialty, geographical region and type of disability. Data collection was supported by a reflexive methodology and analysed by interpretive phenomenological analysis.

Results: The findings reveal four key dynamics shaping the experiences of these professionals: (1) internalised stigma, often rooted in childhood, affects self-concept and identity; (2) medical institutions are ill-equipped to accommodate non-standard bodies, fostering systemic exclusion and isolation; (3) adaptive strategies involve a constant tension between conforming to norms and embracing personal inventiveness, often at the cost of mental fatigue and overwork; (4) care becomes a site of sublimation, where physicians transform vulnerability into clinical strength, challenging traditional definitions of legitimacy in medicine.

Discussion: This discussion offers a cross-sectional reading of the results, comparing them with theoretical frameworks. The contributions of Erving Goffman (stigmatization, self-presentation), Bourdieu (norm, reproduction, habitus), Honneth

(recognition, social justice), Lahire (plurality of trajectories) and Heidegger (relationship to the body, being-in-the-world) have been invoked, among other references, to think about the diversity of trajectories, identity tensions and lived experiences of visible disability.

Conclusion: These trajectories reflect structural limitations in the medical field and call for a paradigm shift towards a more inclusive, empowering model of health care. Rather than correcting individuals, the system needs to evolve to embrace bodily diversity and redefine professional excellence beyond ableist norms.

ID 962- The Cantepau Medical Charter

Jean DOUBOVETZKY

Cantepau Msp, Albi, France

Context: In France, doctors are not generally salaried employees and do not report directly to the health service. They are independent practitioners and their ethics are governed by the Code of Medical Ethics of the National Medical Order, which is included in the Public Health Code. This may be supplemented by commitments or charters specific to various movements or types of practice. The Cantepau Medical Charter was drawn up by a group of general practitioners practising in one of the poorest neighbourhoods in the Occitanie region, whose patients include a large population of homeless people, asylum seekers and drug addicts.

Methods: This charter summarises the choices made by the first doctors at the medical centre more than 30 years ago. It aims to commit all its members to a process of quality and ethics, to make it known to patients and to disseminate it to other healthcare professionals.

Originality: The Cantepau Medical Charter focuses on - unconditional acceptance of patients: accepting (but not necessarily agreeing to) all requests, regardless of the patients' social situation - the independence and freedom of action of doctors, who must act solely

Lessons learned and future implication: The commitments contained in this Charter enable better service to be provided to patients and the community without placing a burden on healthcare professionals. They are actually quite easy to uphold.

Discussion: The Cantepau Medical Charter was drawn up by a small number of practitioners and would undoubtedly benefit from broader consideration by both professionals and patients.

Conclusion: The Cantepau Medical Charter is a document that should be disseminated to promote better ethical and practical thinking about medical practice.

ID 537- Profiles of doctors employed by teleconsultation platforms in France

Louis BRAUN, Frédéric FORTIN

Université Clermont Auvergne, Ufr De Médecine Et Des Professions Paramédicales, Département De Médecine Générale, F-63000 Clermont-Ferrand, France, Clermont-Ferrand, France

Context: Teleconsultation has been booming in France since the health crisis linked to the SARS-CoV2 epidemic. In march 2023, the French National Medical Council (CNOM) published a report on the telemedicine misuse, particularly regarding the risks of teleconsultation exclusive practice. No descriptive analysis of doctors employed by teleconsultation platforms was found in the literature.

Objectives: To determine whether profiles of doctors employed by teleconsultation platforms could be identified based on socio-demographic and professional characteristics.

Methods: A cross-sectional study was conducted in France among a population of doctors employed by five teleconsultation platforms. An online self-administered questionnaire was made available between 30 October 2024 and 30 April 2025.

Results: A total of 342 doctors were included. The average age was 51 (±16 years), 52% were women. Teleconsultation was practiced exclusively by 25% of doctors. Feelings about quality of life and practice were positive for 90% of doctors compared to standard practice, while feelings about remuneration were negative for 26% of doctors. Three profiles were identified. One consisted of a majority of men, retired, practicing teleconsultation exclusively, mainly from home, with a positive perception of teleconsultation. A second consisted of a majority of women, in mid-career, who did not practice teleconsultation exclusively, with a positive perception of teleconsultation. A third group consisted of a majority of women, at the beginning or in the middle of their careers, who did not practice teleconsultation exclusively, had a negative perception of teleconsultation, and did not expect to practice teleconsultation throughout their careers.

Discussion: This study has the strength of involving five major companies in the sector and a participation rate that has enabled to identify three profiles. Its limitations are the desirability bias inherent in self-administered questionnaires, the limited sample size as regard to the estimated payroll and the fact that it does not take account the modalities of teleconsultation practices.

Conclusion: This study seems to show that comfort in life and practice are factors that motivate the teleconsultation practice. Three profiles of salaried doctors have been identified. Many aspects remain to be explored in order to gain a better understanding of these doctors and this rapidly growing practice.

ID 27- Strengthening territorial coordination of care in France: from fragmentation to shared governance

Bruno SAUTERON

General Practitioner, Executive Master In Health Policy And Management (gps), Sciences Po Paris, France, Paris, France

Context: France faces a growing challenge in ensuring equitable and continuous access to healthcare amid population ageing and the increasing prevalence of chronic diseases. Despite successive reforms and the creation of new coordination structures—Primary Care Professional Communities (Communautés Professionnelles Territoriales de Santé, CPTS), Support and Coordination Units (Dispositifs d'Appui à la Coordination, DAC), and Hospital Territorial Groups (Groupements Hospitaliers de Territoire, GHT)—territorial governance remains fragmented and poorly integrated.

Objectives: To identify the main institutional, professional, and digital barriers to effective territorial coordination of care, and to propose realistic strategies for improving equity, efficiency, and quality in primary care organization.

Methods: This qualitative and documentary study was carried out between 2024 and 2025 as part of the Executive Master in Health Policy and Management (Gestion et Politiques de Santé, GPS) at Sciences Po Paris. It combined a comprehensive review of national policy reports—from the High Council for the Future of Health Insurance (Haut Conseil pour l'Avenir de l'Assurance Maladie, HCAAM), the General Inspectorate for Social Affairs (Inspection Générale des Affaires Sociales, IGAS), and the National Health Insurance Fund (Caisse Nationale d'Assurance Maladie, CNAM)—with 20 semi-structured interviews conducted in the 14th district of Paris. Participants included general practitioners, hospital managers, representatives from Regional Health Agencies (Agences Régionales de Santé, ARS), CNAM delegates, and municipal officials involved in local health policies.

Results: Three dimensions of fragmentation were identified: Institutional: overlapping responsibilities between national, regional, and local authorities; Professional: weak interprofessional culture and insufficient recognition of coordination time; Digital: limited interoperability between public e-health tools (e.g., Mon Espace Santé) and private platforms (e.g., Doctolib, Omnidoc). Nevertheless, local initiatives show that shared governance models, interprofessional training, and integrated digital infrastructures can significantly improve continuity of care and collaboration.

Discussion: Territorial coordination must evolve from a top-down administrative injunction to a participatory governance model involving

professionals and local authorities. Recognizing coordination time, fostering mutual trust, and investing in interoperable tools are key levers for transformation.

Conclusion: Coordination is not an accessory but a condition for the survival of equitable, sustainable, and human-centred healthcare. Strengthening territorial governance and valuing teamwork are essential for the future of primary care in France.

ID 2267 - Mobile Application to Support Informal Caregivers of Patients with Alzheimer's Disease Context

Didier CUGY [(1)] , Eric LAVAUD [(2)]

(1) Uhcc, Bordeaux, France
(2) Physiotherapist, Talence, France

Context: Obstructive sleep apnea (OSA) is frequent but remains underdiagnosed in primary care. Screening strategies mainly rely on questionnaires and anthropometric measurements, while clinical observation is often underused. General practitioners routinely observe patients' posture during consultation. Clinical experience suggests that patients with suspected OSA frequently present common postural characteristics, such as forward head posture (FHP) and shoulder curl, which may reflect chronic upper airway constraints and altered autonomic regulation. These postural features are easily observable and reproducible, and could represent an additional clinical approach to improve early identification of patients at risk for OSA in routine primary care practice.

Methods: A retrospective study included 523 patients referred for suspected sleep disorders. Postural parameters (FHP assessed by inion–vertical distance, shoulder curl, shoulder antepulsion) were measured in standing position and correlated with polysomnographic and autonomic parameters using regression analysis and ANOVA.

Originality: This study explores postural assessment as a novel, equipment-free clinical screening approach tailored for primary care. While posture is routinely observed by clinicians, it has rarely been formally evaluated in relation to sleep apnea severity. The originality lies in the use of simple, standardized postural measurements and their correlation with both respiratory and autonomic markers in a large clinical cohort.

Lessons learned and future implications: Simple postural assessment can provide additional clinical clues in patients with suspected obstructive sleep apnea in primary care. FHP and shoulder curl appear to be relevant markers, while not all postural parameters are clinically useful. Integrating postural observation into routine consultation may help improve early identification, guide referral for sleep investigations, and support non-CPAP management strategies, including postural and rehabilitative approaches. Future research should focus on prospective validation and on integrating postural assessment into simplified clinical screening tools for general practice.

Discussion: FHP and shoulder curl are associated with OSA severity ($p < 0.01$) and autonomic parameters, suggesting that posture reflects a clinically relevant respiratory phenotype. Not all postural measures are informative, underlining the importance of targeted clinical observation.

Conclusion: Simple postural assessment, especially forward head posture and shoulder curl, may support earlier identification of obstructive sleep apnea in primary care and encourage integrated, clinically grounded management strategies for patients.

ID 2262 - Determinants of psychological well-being among family physicians: a descriptive study in the context of Türkiye

Kübra EFE, Özlem SUVAK

Etlik City Hospital, Ankara, Türkiye

Context: Headache is one of the most common complaints in primary care. While most cases are primary headaches, changes in headache pattern, inadequate response to treatment and increased analgesic use are red-flag indicators suggesting secondary causes.

Methods: A 45-year-old woman presented to a primary care clinic with a one-year history of progressively worsening headaches, increasing from 1–2 times/month to 4–5 times/week, sometimes waking her from sleep. The pain was throbbing, radiating to the neck, and associated with photophobia, phonophobia and nausea, resulting in significant functional limitation. She had recently been evaluated by neurology, where migraine prophylaxis was adjusted, yet no improvement was achieved, and daily analgesic use increased. Vital signs and neurological examination were normal. Due to the presence of red-flag features, the family physician referred the patient to ENT for neck–carotid imaging. CT angiography revealed a 56×25 mm hypervascular mass, interpreted as a glomus tumor (vagal paraganglioma). Preoperative embolization and surgical excision were performed. The patient recovered well and continued follow-up in primary care.

Originality: The only presenting symptom was headache, without neurological deficit or classic otologic complaints. The diagnosis of a rare glomus

tumor was achieved solely through primary care clinical reasoning and red-flag assessment, not through typical tumor manifestations.

Lessons learned and future implications: Change in headache characteristics requires reassessment. Lack of improvement after specialist evaluation and increased analgesic use should alert clinicians to search for secondary causes. Early referral in primary care can prevent diagnostic delay and improve patient outcomes.

Discussion: Glomus tumors are rare and often present with nonspecific symptoms, leading to potential diagnostic delay. This case highlights the educational importance of recognizing red-flag features in common symptoms such as headache and demonstrates the critical role of family physicians in patient safety, decision-making and coordination of multidisciplinary care.

Conclusion: Early identification of red-flag symptoms and timely referral enabled the diagnosis of a rare glomus tumor, reinforcing the pivotal role of primary care in early detection of serious disease behind common presentations.

ID 2156 - Parents' knowledge, attitudes and practices regarding nasal irrigation in infants: a cross-sectional study in primary care

Isabel GRAÇA [(1)] , Diana PINTO [(2)], Rita AMARAL [(1)]

(1) Usf Aníbal Cunha, Uls Santo António, Porto, Portugal
(2) Usf Bom Porto, Uls Santo António, Porto, Portugal

Context: Syphilis is a re-emerging sexually transmitted infection with a broad clinical spectrum. Secondary syphilis typically presents with a maculopapular rash. Otosyphilis and ocular syphilis are uncommon manifestations that may occur at any stage and mimic frequent benign conditions. These atypical presentations often lead to diagnostic delay and increase the risk of irreversible sequelae.

Methods: We report the case of a 37-year-old male with no relevant medical history who presented to primary care with bilateral otalgia, mild fever, and progressive right-sided hearing loss, and was treated for presumed otitis. In the following weeks, he developed a generalized non-pruritic maculopapular rash and later bilateral ocular hyperemia with reduced visual acuity. Reassessments in primary care and the emergency department attributed ocular signs to conjunctivitis, and no serology testing was performed. One month after symptom onset, persistent visual symptoms prompted ophthalmologic assessment, revealing bilateral anterior uveitis. Given the systemic presentation, syphilis serology was requested and returned positive for VDRL and TPHA, confirming secondary syphilis with otologic and ocular involvement. HIV testing was negative. The patient was treated with intravenous penicillin G for 14 days following neurosyphilis guidelines. At one month follow-up, auditory symptoms had improved only partially.

Originality: Concomitant otosyphilis and ocular syphilis during the secondary stage are uncommon. This case differs from most reports which typically involve a single organ system, highlighting a less-recognized presentation.

Lessons learned and future implications: Primary care clinicians should maintain a low threshold for syphilis suspicion when evaluating unexplained sensorineural hearing loss, persistent ocular inflammation or systemic rash. Early investigation may reduce diagnostic delay and improve auditory outcomes, emphasizing the need for continuous training on atypical syphilis presentations.

Discussion: This case illustrates how common differential diagnosis may mask a multisystem infectious etiology. Delayed recognition of ocular syphilis and otosyphilis is associated with poorer recovery, reinforcing the importance of prompt diagnosis and multidisciplinary collaboration.

Conclusion: Increasing awareness of atypical secondary syphilis presentations and improving diagnostic pathways in primary care is crucial to ensure early detection, to prevent irreversible complications and to limit transmission.

ID 1876 - Evaluation of family medicine residency training in xxx: perspectives of academicians, specialists, and residents"

Susie(Suji) JUNG

Ajou University Hospital, Suwon, Corée (République de)

Context: Previous studies have reported significant associations between cortisol, dehydroepiandrosterone sulfate (DHEA-S), and heart rate variability (HRV) indices, suggesting dynamic interactions between the hypothalamic–

pituitary–adrenal axis and the autonomic nervous system.

Objectives: The objective of this study was to apply an unsupervised machine-learning clustering approach based on adrenal hormones and HRV indices to identify stress response phenotypes in healthy adults, and to examine their dynamic interactions and associated clinical and metabolic risks.

Methods: This retrospective cross-sectional study included 1,200 healthy adults. Morning fasting assessments covered demographics, anthropometrics, questionnaires on stress, fatigue, and sleep, routine labs, adrenal hormones (cortisol, DHEA-S, cortisol/DHEA-S ratio), HRV indices (SDNN, RMSSD, TP, LF, HF, LF/HF), and urinary metabolites. Non-normal variables were log-transformed, with normality confirmed via Shapiro–Wilk tests. Spearman correlations explored hormone-HRV associations. K-means clustering (k=3) classified participants using DHEA-S, cortisol/DHEA-S ratio, RMSSD, TP, and HF. Cluster differences were evaluated by Kruskal–Wallis, Wilcoxon rank-sum, and chi-square tests, with all analyses performed in R 4.5.1.

Results: Significant positive correlations were observed between DHEA-S and LF, TP, SDNN, HF, and LF/HF, with a negative correlation between cortisol/DHEA-S ratio and these HRV metrics. Clustering revealed three distinct phenotypes. Cluster 1 had low HRV, high LF/HF, and strong positive DHEA-S–HRV correlations. Cluster 2 showed intermediate HRV but low DHEA-S and high cortisol/DHEA-S ratio, with disrupted hormone-HRV correlations. Cluster 3 exhibited high HRV and favorable hormone profiles with inverse correlation patterns to Cluster 1. Metabolic profiling showed Cluster 1 had elevated insulin resistance and inflammation with high fatigue and stress, Cluster 2 showed oxidative stress and aging markers, while Cluster 3 had protective parasympathetic and metabolic profiles.

Discussion: Distinct physiological stress phenotypes relate to heterogeneous metabolic, inflammatory, and oxidative profiles and varying subjective stress fatigue, reflecting complex HPA–autonomic system interactions. Limitations include cross-sectional design, requiring prospective studies for causal inference and disease outcome evaluation.

Conclusion: Adrenal hormone and HRV-based clustering identify heterogeneous stress response phenotypes with distinct clinical and metabolic risks in healthy adults, presenting a framework for personalized risk assessment in precision medicine. Future longitudinal validation is warranted.

Paolo Augusto ROMERO MERINO, Rosa Maria GONZÁLEZ LÓPEZ, Carmen DE SANTIAGO GONZÁLEZ, Carlos Eduardo GOMES RODRIGUES CORREIA, Ayeiza Maria FELIPE LEMES

Centro De Salud Arrabal De Portillo, Valladolid, Espagne

Context: Superior mesenteric artery syndrome (SMAS), or Wilkie's syndrome, is a rare cause of duodenal obstruction resulting from reduced aortomesenteric distance. Its symptoms overlap with common gastrointestinal complaints frequently seen in primary care, which often leads to diagnostic delays. This case highlights the relevance of continuity of care and multidisciplinary coordination in identifying severe malnutrition secondary to SMAS.

Methods: A 38-year-old woman was referred from internal medicine to primary care for nutritional assessment due to significant weight loss. She had experienced progressive reduction in oral intake and postprandial abdominal pain over one year, reporting a 6.4 kg loss from her habitual weight of 54 kg. She denied nausea or vomiting and had occasional constipation and diarrhea. Examination revealed BMI 16.8 kg/m², reduced muscle mass, and minimal physical activity. An abdominal CT scan showed gastric dilation with a markedly reduced aortomesenteric angle of 12°, decreased aortomesenteric distance (4 mm), and compression of the third duodenal portion, supporting the diagnosis of SMAS. Additional findings included left ovarian vein dilation and periuterine venous varicosities consistent with pelvic congestion syndrome. Liver, pancreas, and kidneys were normal. Duodenal biopsies showed preserved villous architecture, excluding celiac disease. Given the severity of malnutrition, the patient was started on high-calorie oral supplements and instructed to take frequent small meals.Vascular surgery evaluated the possibility of endovascular intervention, including superior mesenteric artery stenting or alternative approaches, given the persistence of symptoms.

Originality: This case illustrates an uncommon etiology of chronic abdominal pain and severe weight loss, demonstrating the diagnostic complexity of SMAS and its overlap with functional or nutritional disorders.

Lessons learned and future implications: Early recognition of red flags—progressive weight loss, early satiety, and postprandial pain—is essential in primary care. SMAS should be considered in low-BMI patients with persistent upper abdominal symptoms.Timely imaging and multidisciplinary management can prevent complications.

Discussion: Family medicine plays a central role in longitudinal monitoring of nutritional status, evaluating persistent gastrointestinal symptoms, and coordinating referrals.This case emphasizes how primary care continuity supports the identification of rare conditions and optimizes patient outcomes.

Conclusion: Severe malnutrition secondary to SMAS requires high clinical suspicion, prompt imaging, and coordinated care.Early intervention can improve nutrition and quality of life.

ID 1811 - Algorithm-based validation of sleep apnea treatment: lessons from primary care after one year

Hyoeun KIM [1] , Jongsoon CHOI [2]

(1) Department Of Family Medicine, Inje University Haeundae Paik Hospital, Busan, Republic Of Korea, Busan, Corée (République de)
(2) Department Of Family Medicine, Kosin University Gospel Hospital, Busan, Republic Of Korea, Busan, Corée (République de)

Context: Type 2 diabetes (T2D) reflects interactions between inherited susceptibility and metabolic burden. Individuals with similar lifestyles may show differing risk, suggesting that genetic influences can become observable to varying degrees depending on metabolic status. The Korean Genome and Epidemiology Study (KoGES), a large population-based cohort with extensive genomic and metabolic data, enables evaluation of how insulin resistance and visceral adiposity relate to the detectability of T2D-associated loci. Metabolic burden was quantified using the Metabolic Score for Insulin Resistance (METS-IR) and the Metabolic Score for Visceral Fat (METS-VF).

Objectives: To determine whether T2D-related genetic associations differ across strata defined by insulin resistance and visceral adiposity, and to explore how these metabolic dimensions relate to the expression of inherited susceptibility.

Methods: Participants with complete METS-IR (n=70,583) and METS-VF (n=70,513) data were included. Each index was divided into tertiles (T1 vs T3). T2D was defined using fasting glucose, HbA1c, or prior diagnosis. Stratified genome-wide association analyses were performed using additive models adjusted for demographic, lifestyle, and population-structure covariates (genome-wide significance: $p<5\times10^{-8}$).

Results: T2D prevalence rose from T1 to T3 for both METS-IR (5.6%→30.3%) and METS-VF (6.0%→30.2%) ($p<0.001$). Distinct genetic patterns emerged across strata. In the METS-VF analysis, loci including CDKAL1, SLC30A8, CDKN2B-AS1, and HNF4A showed stronger associations in T3, suggesting that visceral fat may amplify the phenotypic expression of genetic tendencies. In contrast, METS-IR revealed loci more prominent in T1—such as HHEX, CNNM2, CPEB3, and PTPN11—indicating that some signals are most detectable under favorable metabolic conditions and may become attenuated as insulin resistance increases.

Discussion: METS-VF tended to accentuate major T2D loci under higher metabolic burden, whereas METS-IR captured signals evident at lower burden. These differences may help explain variation in diabetes risk among individuals with similar lifestyles. Prior evidence also shows that healthier metabolic profiles can lessen the expression of inherited vulnerability, and our findings suggest that both high- and low-burden groups may benefit from reducing metabolic stress to maintain lower risk.

Conclusion: Insulin resistance and visceral adiposity showed distinct patterns of genetic association with T2D. Awareness of these stratified patterns may help primary care clinicians better contextualize individual diabetes risk and guide personalized metabolic prevention strategies.

Context: Integrated care for individuals with type 2 diabetes (T2D) and arterial hypertension (AH) should be accessible, continuous, and person-centred. However, formal healthcare systems often struggle to sustain long-term self-management support. Community-based peer support, provided by individuals with lived experience, may enhance continuity and quality of care by offering emotional, social, and practical assistance.

Objectives: To explore the role and contribution of trained peer supporters in strengthening integrated primary care for people with T2D and AH in XXX.

Methods: A prospective interventional mixed-methods study was conducted between May 2021 and December 2023 at two primary healthcare centres: the urban Community Health Centre XXX and the rural Community Health Centre XXX. A purposive sample of 36 individuals with T2D and AH, completed a two-month structured educational programme to become trained peer supporters for other patients (n=226). Participants attended monthly peer support meetings over three months. Quantitative data were collected from medical records, clinical measurements, and questionnaires, while qualitative insights were gathered through interviews and focus groups. Statistical analyses included paired t-tests and multivariate linear regression.

Results: Thirty-one participants (retention 86.1%) completed the training (mean age 63.9±8.9 years; 67.7% women). The intervention was feasible, acceptable, and effective. Training significantly improved knowledge of T2D ($p<0.001$) and AH ($p=0.024$), and BMI decreased from 30.4 to 29.8 after six months ($p=0.020$). Three peer support meetings were attended by 200 patients (retention 88.5%; mean age 68.3±10.5 years; 51% male), resulting in a significant increase in empowerment ($p<0.001$). Higher empowerment was associated with younger age ($p=0.009$), rural residence ($p<0.001$), and not receiving antihyperglycaemics ($p=0.015$). Qualitative findings highlighted the value of accessibility, empathy, and informality in fostering trust, reducing stigma, and promoting open communication.

Discussion: Adequately trained peer supporters can complement healthcare professionals by enhancing patient engagement and continuity of care. The success of such programmes depends on clear role definition, ongoing training, and sustained motivation.

Conclusion: Peer support is a compassionate and sustainable complement to primary healthcare for people with T2D and AH. By fostering trust, self-efficacy, and social connectedness, it strengthens integrated care and warrants policy support and further research on long-term impact and scalability.

ID 1760 - Determinants of Health Information Fidelity: The Role of Health Locus of Control in Rental-Flat Seniors

Didier CUGY

Uhcc, Bordeaux, France

Context: Algorithm-based validation of medical prescriptions is increasingly used to standardise care. Since June 2024 in France, prescriptions for continuous positive airway pressure (CPAP) therapy for sleep apnea must be validated through a national algorithm based on French National Authority for Health (HAS) criteria. While this system aims to improve efficiency and equity, its impact on complex, real-life primary care situations—where clinical judgement is essential—remains poorly documented.

Methods: We conducted a practice-based retrospective review of electronically submitted CPAP prescriptions between June 2024 and September 2025. Data from 127 submissions were analysed to document algorithm-based decisions, administrative outcomes at the Commission de Recours Amiable (CRA), and the role of the general practitioner (GP) in the appeal process.

Originality: This contribution provides a rare real-world primary care perspective on the practical limits of algorithm-based medical validation. It explores how digital decision-support systems may outweigh general practitioners' clinical assessment of treatment benefit. Rather than a theoretical evaluation of artificial intelligence, this reflection highlights how administrative frameworks can shape the balance between algorithms and professional judgement in everyday practice.

Lessons learned and future implications: The analysis showed that 30% of prescriptions were rejected by the validation system. Rejections mainly concerned patients whose clinical profiles were consistent with international recommendations but did not meet national threshold-based criteria. Several patients had an apnea–hypopnea index below 15/h but significant respiratory events during REM sleep or in the supine position. The appeal process relied exclusively on the initial algorithm-based opinion, without medical reassessment, and did not integrate the GP's documentation of clinical improvement. Older patients with multimorbidity or cognitive impairment were particularly affected.

Discussion: This reflection highlights tensions between algorithm-driven decision-making and the realities of primary care. Reliance on global numerical thresholds may overlook clinically meaningful situations, while the absence of a medical reassessment pathway during appeals undermines continuity of care and professional responsibility.

Conclusion: Algorithm-based validation should support, not replace, clinical judgement. Digital decision-support systems need to evolve to integrate contextual clinical information and observed treatment benefit, ensuring that standardisation does not limit patient-centred care.

ID 1728 - Before/After study of a Decision Aid for women eligible for breast cancer screening

Matteo GALEA, Nathaniel FENECH, Joanna THOMPSON

Primary Health Care, Paola, Malte

Context: Abdominal radiography typically offers limited diagnostic value with relatively low sensitivity and specificity. According to the National Radiation Protection Board, one abdominal x-ray (AXR) is equivalent to thirty chest x-rays. To guide its appropriate use, the iRefer guidelines developed by the Royal College of Radiologists (RCR) provide recommendations on when AXRs may provide useful diagnostic information.

Objectives: To determine whether AXR indications in general practice align with the RCR iRefer guidelines.

Methods: All patients who had an AXR performed in health centres in XXX between January and June 2025 were included. Data collected included patient demographics, request details for AXRs and x-ray reports.

Results: A total of 148 AXRs were taken, approximately 25 x-rays monthly. 57% of patients were male and 43% female. Ages ranged from 2 to 89 years, with the commonest age group being 60 years and over. All AXRs had an indication present, with 52.7% regarded as appropriately indicated as per iRefer guidelines, while 47.3% were not indicated. The commonest indication was suspected bowel obstruction (34.5%), followed by abdominal pain (17.6%) and constipation (13.5%). Faecal loading was the commonest reported finding (52.7%). Only 7.8% of AXRs ordered in view of suspected bowel obstruction showed actual evidence of obstruction, whilst in those taken in view of foreign body ingestion, 36.8% showed evidence of a radio-opaque substance.

Discussion: Compliance with RCR guidelines when ordering AXRs in general practice was not optimal. Although there is limited literature available on the subject, our findings showed that there might be AXR overuse in general practice. This might be stemming from the notion of ordering AXRs as a "screening tool" to rule out serious pathology and the lack of familiarity with the RCR guidelines. A limitation of our audit was that our results were influenced by the quality of the documented x-ray indication by the requesting physician, which might have led to misclassification of guideline adherence.

Conclusion: Our study highlighted that almost half of AXRs performed in general practice in XXX were not indicated as per iRefer guidelines. Increasing awareness of the indications for abdominal radiography can limit unnecessary radiation exposure and improve quality of patient care.

ID 1658 - Assessing the Suitability of Abdominal X-ray Requests in General Practice

Harlan MOLHO, Emmanuel CHAZARD, Matthieu CALAFIORE, Anne GARAT, Ramy AZZOUZ

University Of Lille, Lille, France

Context: Poisonings are a common reason for consultation, yet long-run large-scale XXX epidemiology is scarce. The XXX Poison Control Centre's historic XXX database, curated from 1988 to 2020, offers a 33-year window on exposures across ages and contexts.

Objectives: To improve primary-care prevention by characterizing trends, risk groups and substances in cases reported to the Centre, using indicators aligned with international studies.

Methods: Retrospective descriptive analysis (1988-2020) of the XXX (XXX XXX XXX XXX XXX) database (SQL extraction). Age, circumstances and substances were mapped to identify trends and emerging risks.

Results: Among 662,179 cases, calls increased until 2013. Children aged 1–5 years were most affected (46.6%). Circumstances were dominated by domestic accidents (67.9%), followed by suicidal ingestions (12.7%), and therapeutic errors (12.1%). Suicidal poisonings mainly involved adolescents (56% in 13–20y). Domestic accidents remained stable, mostly in children. Frequent substances were household detergents (9.1%), benzodiazepines (7.3%), and paracetamol (5.7%). Detergent exposures were almost exclusively accidental (65.8% for <5-year-old; 91.8% accidental). Benzodiazepines and paracetamol were often linked to suicidal intent. Over time, domestic accidents remained stable, while adolescent suicidal poisonings persisted and therapeutic errors rose steadily. Opioid exposures increased nearly fourfold (notably tramadol +311%, codeine +229%, opium +730%), mostly with suicidal intent (48.6%). Most cases were asymptomatic or mild; severe/fatal cases were <1% (574 deaths).

Discussion: Long-term trends show stable paediatric domestic poisonings but persistent adolescent suicidal exposures, especially involving benzodiazepines, paracetamol and opioids. Rising therapeutic errors and the marked increase in opioid cases mirror national patterns and highlight preventable iatrogenic risks. Most exposures were asymptomatic, yet severe presentations clustered in adolescent self-harm. These findings are consistent with international toxicovigilance data and underscore the need for targeted prevention, improved prescribing practices ("less is more" approach), and early GP-led intervention. Integrating similar analyses into a nationwide database would strengthen surveillance capacity and support future public-health action.

Conclusion: This is the largest longitudinal poisoning study in XXX. It reveals enduring paediatric domestic risk, sustained adolescent self-harm, and a rising opioid signal. Insights can guide GPs' anticipatory guidance, safe-use counselling and early intervention.

ID 1521 - Frequent relocation as a barrier to continuity of care: a case report highlighting negative outcomes associated with care fragmentation.

Alice NEVES, Luísa PRUDENTE, Tainá MORAES, Mariana GOMES, Clara MUGUET, Paulina BOESEL, Joana COSTA, Layon PATRICK, Andreia SCHUABB, Mariana SILVA

Idomed, Rio De Janeiro, Brésil

Context: Primary healthcare (PHC) provides patient-centred care supported by community resources that enhance health and quality of life. This project aimed to improve access to resources by adapting the ecomap concept into a wall-mounted map within a PHC unit. The initiative strengthened support networks, promoted health equity for vulnerable populations, and facilitated connections between healthcare teams and the community. It was guided by the ecomap framework and the Ottawa Charter (WHO, 1986).

Methods: The project was conducted from July 2024 to July 2025 at a PHC unit and teaching site of IDOMED University of Medicine in Rio de Janeiro, Brazil. The initiative adapted the ecomap concept into a resource map supported by cards summarising contacts. Systematic visits and semi-structured interviews identified and documented twenty free-of-charge social initiatives, an assistance centre for unemployed individuals with disabilities, organisations offering food, clothing, an Alcoholics Anonymous centre, a community empowerment hub for Black women, and a wellness therapy for patients experiencing chronic pain. Activities were coordinated by medical students under supervision. Qualitative feedback showed increased engagement resources. Strengths included cost participatory design; limitations

involved restriction absence of quantitative outcomes.

Originality: Few initiatives in the literature have adapted the ecomap concept into a physical, interactive wall display within PHC settings. This project introduced a low-cost, participatory, engaging tool that transformed abstract social resource mapping into a tangible and accessible instrument for use.

Lessons learned and future implications: The experience reinforced the value of community integration in patient-centred care and highlighted the importance of visual communication tools in promoting health equity. Future steps may include digital versions of the map and evaluation of outcomes such as referrals and satisfaction. The project underscored the role of students in developing innovative public health strategies and can be integrated into primary care training.

Discussion: The wall-mounted map and resource cards proved practical, interactive and accessible for patients and health professionals, fostering collaboration and engagement within the PHC unit.

Conclusion: Mapping community assets can support autonomy, promote equity, and foster solidarity through collective action. Although implemented locally, the approach is adaptable to other PHC contexts and may inform policies and training programmes aimed at integrating community resources into primary healthcare.

Context: Targeted antimicrobial susceptibility testing (AST) enhances urinary track infections antibiotic stewardship by supporting recommended empiric treatments and reducing the use of critically important antibiotics. As recommended by HAS 2023, partial AST reporting applies only to positive enterobacteria urine cultures in women and girls aged ≥12 years. Despite their potential benefits, the extent of their implementation in routine laboratory practice remains unclear.

Objectives: To assess the implementation of targeted AST in French medical laboratories, identify barriers to adoption, and explore factors facilitating their use.

Methods: A 23-section questionnaire was developed by 12 biologists and physicians from 7 regions. It covered laboratory characteristics, implementation modalities, frequency of use, communication strategies, professional perceptions, and identified barriers and facilitators. The survey was distributed between March and June 2025 through the Regional Antibiotic Therapy Centers Network, Mobile Antibiotic Therapy Teams, the Ministry's Infection Prevention and Antimicrobial Resistance Mission, social media, and direct contacts with independent laboratories, with multiple reminders. Descriptive analysis was performed using frequencies and percentages.

Results: A total of 148 biologists responded, representing 91 departments (90%) and about 52% of French laboratories. Of these, 65 (44%) reported using targeted AST. Among the 83 non-users, the main barriers were insufficient human or material resources (n=54; 63%) and lack of time (n=34; 41%). Among the 65 users, 50 (78%) complied with national health authority recommendations, while 27 (41%) extended targeted AST to male and/or pediatric urinary tract infections. Prescriber adherence was considered good by 60 respondents (92%). The main limitations reported by users were poor quality of clinical information provided on prescriptions (n=49; 75%) and difficulties in obtaining additional patient data when needed (n=38; 58%).

Discussion: Only 44% of respondents use targeted AST, primarily hindered by organizational constraints rather than scientific disagreement. However, strong prescriber adherence and extension to men and children demonstrate growing acceptance.

Conclusion: Targeted AST faces significant implementation barriers but shows promising results. To facilitate adoption, the Regional Antibiotic Therapy Centers Network provides a standardized prescription form and informational letter. Addressing resource limitations and improving clinical information quality remain key priorities. Extension to other clinical contexts represents a valuable lever for enhancing antimicrobial stewardship in primary care.

ID 1371 - Rural -urban measles/mumps/rubella vaccination rate comparison

Lucie O'KEANE, Jean-Baptiste JEAU

Nantes University, Nantes, France

Context: The goal of environmental health is to identify environmental exposure threatening human health, in order to control, reduce and prevent its impacts. Recent massive environmental change is of interest in studies due to its link to health in general. Health systems undergoing a “green” transition allow an opening for healthcare workers to participate in the inclusion of environmental factors in care.

Objectives: Our main goal in this thesis was to study the way primary healthcare workers in the XXX region practice with environmental health in mind. The different level of interest between professions was also a point of interest.

Methods: Ours is an observational, transversal, descriptive study. The medium used is an online questionnaire shared via email to various healthcare workers, including general practitioners, nurses, midwives, physiotherapists and pharmacists shared between April and July 2024.

Results: We included 128 healthcare workers in our study. A majority of them were general practitioners, working in a semi rural area, more often young women settled in their practice for more than ten years, and having some previous knowledge of environmental health. Our study shows a positive correlation between personal life and professional life interest in environmental health. Midwives give significantly more preventive environmental health advice. Healthcare workers report needing better training and more time to include environmental health in care.

Discussion: Our participation rate was very low, estimated at 1,5%. Our sample is therefore not representative of the primary healthcare workers of the region XXX. Our study seems to show increasing interest in healthcare workers for environmental health compared to previous studies. However, interest seems lower when compared to other countries experiencing climate change more acutely. Within our sample, there is differential interest within the professions when it comes to environmental health.

Conclusion: Primary healthcare workers in our study seem to be aware of the importance of environmental health. However, there is insufficient training and an important time constraint preventing them from including it in care. Complementary studies on patient expectations from healthcare workers could be of interest in the future.

ID 217 - Attitudes and Expectations on practice-based Digitisation of Young XXX Primary Care Workforce: Reflections from a Survey Development

Linda BELMELIANI, Corinne BOIS

Department Of General Practice, Université Paris-Est Créteil, Creteil, France

Context: Nasal irrigation is a first-line recommended intervention for upper respiratory tract infections in infants. In daily practice, this care is mainly performed by parents at home, often without direct supervision. Despite its frequent recommendation in primary care, little is known in France about parents’ knowledge, attitudes and practices (KAP) regarding nasal irrigation and the difficulties they experience when performing this procedure.

Objectives: To describe parents’ knowledge, attitudes and practices regarding nasal irrigation in infants, and to identify factors associated with the perceived difficulty of this procedure.

Methods: We conducted a quantitative cross-sectional descriptive study among parents of infants aged 2 to 6 months. Participants were recruited in a maternity ward in the Paris metropolitan area between October and December 2024. Data were collected using a structured questionnaire exploring parental practices, sources of information, perceived difficulty (rated on a 1–10 scale), and the child's behaviour during nasal irrigation. Descriptive and bivariate analyses were performed using non-parametric statistical tests.

Results: A total of 120 parents completed the questionnaire. Most participants reported using saline solution for nasal irrigation and demonstrated good theoretical knowledge of recommended practices. However, 71.7% of parents reported significant infant agitation during the procedure. Infant agitation was significantly associated with higher perceived difficulty (median score 4 vs 2; $p < 0.001$). Parents benefiting from follow-up by primary care professionals within maternal and child health services (PMI) reported a trend toward lower perceived difficulty, although this difference did not reach statistical significance. Educational videos were frequently used as a source of information, regardless of parental educational level.

Discussion: Although parental knowledge regarding nasal irrigation appears satisfactory, the procedure remains emotionally challenging for many families. Infant agitation strongly influences parents' perception of difficulty and may affect adherence to recommended practices. The widespread use of heterogeneous online educational resources highlights the need for validated and standardized educational tools.

Conclusion: Nasal irrigation in infants, while simple, is frequently experienced as difficult by parents in primary care. Standardized parental education involving general practitioners and maternal and child health professionals could improve parents' confidence and promote safer practices. Developing educational resources tailored to primary care may strengthen preventive care and partnerships.

ID 1250 - Impact of Having a Primary Care Physician on Adherence to Antiretroviral Therapy Among HIV-Positive Patients.

Şevval Dilan YAĞMUR, Adem ÖZKARA, Aylin BAYDAR ARTANTAŞ

Ankara Bilkent City Hospital, Department Of Family Medicine, Ankara, Türkiye

Context: Family medicine (FM) constitutes the backbone of primary health care systems and requires residency training programs that are responsive to changing population needs and health system demands.

Objectives: In XXX, major regulatory reforms over the past decade have reshaped FM residency training, including the balance between hospital and community-based training, elective rotations, and contracted residency pathways. However, contemporary stakeholder-informed evaluations remain scarce. This study aims to assess the current status of FM residency training in XXX and to develop evidence-based recommendations.

Methods: This is an ongoing cross-sectional quantitative study conducted among family medicine academics, specialists, and residents in XXX, XXX. A structured questionnaire developed by the research team collects sociodemographic data and participants' views on training duration, rotations, field training, additional practice areas, and career expectations. The planned sample size is 275 participants. The results presented here reflect an interim analysis based on data from the first 90 respondents. Descriptive and inferential statistical analyses are being performed with a significance level of $p<0.05$.

Results: Interim findings indicate that most participants consider the current 3-year training model (18 months hospital rotations and 18 months field training) appropriate in structure; however, satisfaction with the quality of theoretical and practical training, particularly among full-time residents, is moderate. There is strong demand for additional rotations in ophthalmology, otorhinolaryngology, geriatrics, orthopedics and traumatology, child and adolescent psychiatry, and radiology. Participants also emphasize the need to strengthen structured field practice in obesity, hypertension, diabetes, chronic wound care, and geriatric care. Furthermore, 74.0% support the development of structured post-residency subspecialty programs, especially in geriatrics, public health, and sports medicine. Approximately one quarter report considering training in another specialty, mainly due to perceived limitations in training quality and employment conditions.

Discussion: Preliminary results suggest that, while FM residency training in XXX is generally perceived as adequate, important areas for improvement exist, particularly in educational quality,

standardization of rotations, and reinforcement of community-based training. The study is ongoing, and final analyses based on the complete sample will be presented at the congress.

Conclusion: These findings are expected to provide robust evidence to inform curriculum development and policy decisions aligned with European training standards.

(1) Yong Loo Lin School Of Medicine, National University Of Singapore, Singapore, Singapour
(2) Lee Kong Chian School Of Medicine, Nanyang Technological University, Singapore, Singapour

Context: Preventive care engagement in Singapore remains uneven despite extensive national efforts to promote screening and early intervention. In 2023, over 40% of eligible seniors falling short of screening recommendations, reflecting persistent uptake gaps even within a well-resourced primary care system. Health perceptions, specifically Health locus of control (HLOC) - beliefs on forces shaping one's health and the value placed on health, can influence how effectively individuals navigate health systems. Information fidelity, defined here as accurate recall of health programme information and correct understanding of required procedures, represents an essential but understudied mechanism linking health beliefs to actual engagement. However, the interaction between HLOC domains and information processing capacities in Asian older adults, particularly those experiencing socioeconomic vulnerability, has not been clearly delineated.

Objectives: This study evaluates associations between HLOC dimensions and health-programme information fidelity among older residents of public rental housing.

Methods: A cross-sectional survey was carried out among Toa Payoh rental-flat residents in 2025. Participants completed Multidimensional HLOC-adapted questionnaires (Likert 1-5 scales) on 3 domains: Internal control, external control and health prioritization. Information fidelity was assessed across 2 components: declarative recall and procedural understanding, each coded on a binary scale. Linear regression models evaluated associations between HLOC dimensions and information fidelity as continuous variables, adjusting for age, gender and Community Health Assist Scheme (CHAS) card status. Significance was set at $p<0.05$.

Results: Of 116 participants (50.9% female; mean age 64.0±10.8; 72.4% CHAS Blue), external HLOC (mean=2.79±0.71) showed no significant association with declarative ($p=0.268$) or procedural information ($p=0.970$). Internal HLOC (mean=3.75±0.46) correlated positively with declarative information only ($\beta=0.193, p=0.025$). Unexpectedly, stronger health prioritisation beliefs (mean=3.25±0.46) were negatively associated with procedural understanding ($\beta=-0.156, p=0.041$).

Discussion: Findings suggest strong internal control beliefs or stated health prioritisation do not reliably translate into accurate health programme understanding. The observed intention-behaviour gaps may reflect structural, cognitive or contextual barriers which can interfere with information processing in preventative efforts.

Conclusion: Thus, integrating patient-empowerment approaches with simplified and consistent communication strategies within primary care may support more equitable personalised care provision.

(1) Family Medicine Department, Sfax, Tunisie
(2) Occupational Medicine Department, Hedi Chaker University Hospital, University Of Sfax, Sfax, Tunisie

Context: Medical training overlaps with peak reproductive years and is characterized by heavy workload, unpredictable schedules, and limited institutional support. These constraints may interfere with medical trainees' ability to pursue a parental project (PP).

Objectives: This study aimed to (1) assess gender differences in perceptions of PP feasibility, (2) describe reproductive health challenges and pregnancy-related experiences among medical

trainees, and (3) identify gender-specific predictors of perceived PP difficulty

Methods: A national cross-sectional survey was conducted between July and December 2024 among interns and residents from the four medical faculties in Tunisia. An anonymous online questionnaire collected sociodemographic data, reproductive history, perceived barriers to PP, work-related quality of life (WRQoL), and job satisfaction (PJS). Gender-based comparisons were performed using appropriate statistical tests. Predictors of perceived PP difficulty were explored through multivariate logistic regression.

Results: Among the 1,230 respondents, 68% were women. More than half of married female trainees (53%) had experienced at least one pregnancy during training, frequently complicated by preterm labor (31%), hypertensive disorders, or early pregnancy losses. Dissatisfaction with maternity leave duration was reported by 51.7%. Perceived PP difficulty was significantly higher among women (57%) than men (36%) ($p < 0.001$). Gender disparities were also noted in perceived obstacles: women frequently cited academic penalties, stigma related to pregnancy, and insufficient support from supervisors or institutions, whereas men more often referred to financial and organizational barriers.

Discussion: Findings highlight substantial reproductive challenges among medical trainees, particularly women, who face both biological and structural disadvantages. High rates of pregnancy complications and dissatisfaction with maternity leave suggest insufficient adaptation of working conditions to reproductive needs. Persistent stigma and fear of academic repercussions further reinforce gender inequities.

Conclusion: Medical training in Tunisia is associated with considerable gender-specific constraints affecting reproductive health and PP feasibility. Implementing gender-responsive measures—including protected rotations, extended maternity leave, supportive supervision, and anti-stigma policies—is critical to promoting equity and enabling trainees to reconcile medical training with reproductive choices.

(5) Own General Practice, Berlin, Allemagne
(6) 2. Xxx Cohort, Berlin, Allemagne

Context: Attracting and retaining young professionals is a key challenge for primary care in Germany and across Europe. While numerous studies address digitisation, workload, and professional satisfaction, they mainly focus on established or older General Practitioners (GPs). The perspectives of young general practitioners and practice staff remain largely unexplored. Understanding their expectations, concerns, and experiences is essential to shape the future of family medicine.

Methods: Within the XXX network of the German Society of General Practice and Family Medicine German, we as early career researchers initiated a collaborative project to develop a national survey on the experiences and visions of young professionals for digitisation of general practice. We conducted a scoping literature review, identified key themes, and examined prior surveys mainly conducted among older GPs. The questionnaire was iteratively developed using cognitive testing, expert consultations, a focus-group workshop and input from open-access large language models (LLMs). Challenges included balancing scientific rigour with practical feasibility, defining “young general practice” as a target group, and ensuring inter-professional inclusivity across different professions including physicians, medical assistants, and physician assistants.

Originality: This initiative is among the first in Germany to systematically examine the perspectives of the next generation of primary care professionals regarding digitisation. Unlike prior

studies, it emphasises early-career voices and their expectations for digital tools in practice.

Lessons learned and future implications: Collaborative work among early-career researchers helped navigate conceptual and methodological challenges. Capturing young professionals' diverse attitudes – whether enthusiastic or cautious – is crucial for informing digital tool implementation, workflow design, and workforce planning in primary care.

Discussion: Engaging young professionals early may reveal insights that differ from older practitioners' perspectives, highlighting opportunities, concerns, and barriers in digital adoption. Reflection on the development process can guide future initiatives, support inter-professional collaboration, and identify priorities for training, policy, and practice transformation.

Conclusion: Reflecting on survey development shows the value of engaging young professionals in shaping research agendas and workforce strategies. Understanding their perspectives on digitisation is key to designing primary care practices that are motivating, sustainable, and capable of delivering high-quality patient care.

(4) Cs Valdespartera, Zaragoza, Espagne

Context: Echocardiography is a diagnostic tool increasingly used in European primary care to assess symptomatic patients with suspected cardiovascular disease. However, real-world evidence regarding its clinical impact is limited.

Objectives: To evaluate the clinical usefulness and impact of echocardiography on case management in primary care, describing indications, main findings, and resulting clinical actions.

Methods: Observational descriptive study of 100 consecutive patients seen between January and October 2025. Inclusion criteria: age >15 years, clinical indication for echocardiography (dyspnoea, systolic murmur, palpitations, atrial fibrillation, chest pain, syncope, ECG abnormalities, new-onset heart failure, cardiomegaly). Trained family physicians performed all scans. Variables included: indication for test, echocardiographic findings (ventricular function, chamber size, valve insufficiency/stenosis, pericardial effusion), and clinical impact (diagnostic confirmation/modification, therapeutic adjustment, referral to cardiology). Analysis: absolute and relative frequencies.

Results: Most frequent indications were new-onset heart failure (17%), ECG abnormalities (12%), dyspnoea (11%), systolic murmur (11%), palpitations (10%), atrial fibrillation (9%). Findings were normal in 38% of cases. Main pathological findings: heart failure (15%), aortic stenosis (6%), atrial fibrillation without structural alterations (8%). Echocardiography led to diagnostic or clinical adjustment in 49% of cases, therapeutic modification in 37%, and specialist referral in 29%.

Discussion: Systematic use of echocardiography in primary care optimizes rapid etiological assessment and individualized management, enabling safe exclusion of significant disease and guided intervention or referral for patients with structural findings. Our experience aligns with published guidance and highlights the need for specific training. The main limitation was the observational design and lack of a systematic comparison with standard echocardiography.

Conclusion: Echocardiography enhances diagnostic accuracy and efficiency for cardiovascular problems in family medicine, supporting individualized care and rational resource use. Controlled and multicentric studies are needed to confirm these findings in a broader setting.

Delphine RUBÉ [(1)] , Chiara SABATINO [(2)] , Loriane BONNET [(3)]

(1) Dumg Tours, Bourges, France
(2) Dumg Tours, Petala Soprana, Italie
(3) Dumg Tours, Tours, France

Context: In France, an increasing number of general practice residents completed their second cycle of medical studies in another European Union country before entering residency. This situation

affects both learners adapting to a new healthcare and training environment, and general practice supervisors (MSUs) responsible for accompanying them. Understanding the experiences, difficulties, and strengths perceived by both groups is essential to improving integration and training quality.

Objectives: To explore the experiences of EU-trained general practice residents and the supervisors hosting them in the Centre-Val de Loire region, and to identify barriers, facilitators, and improvement strategies supporting successful integration.

Methods: Two qualitative studies were conducted using semi-structured individual interviews. The first included 13 residents who completed their second medical cycle in another EU country (French, Italian, Romanian participants). The second involved 12 general practice supervisors (MSUs) from the same region. Interviews explored integration, perceived difficulties, teaching conditions, and adaptive strategies. Data were analyzed thematically using interpretative phenomenological approaches.

Results: Residents and supervisors reported significant challenges: language barriers, administrative difficulties, and adaptation to the French healthcare system. Supervisors highlighted strong heterogeneity among residents and delayed autonomy, often increasing their workload and raising questions about their teaching role. Residents reported experiencing prejudices regarding their prior training abroad. Nevertheless, both groups emphasized high motivation, substantial progression, supportive tutoring, and enriching intercultural exchanges. Supervisors frequently developed adaptive strategies, and most placements were ultimately considered successful.

Discussion: The combined findings highlight a dual dynamic: substantial integration challenges for residents and increased pedagogical burden for supervisors, but also meaningful professional and cultural benefits. The importance of structured supervisory support, clear pedagogical frameworks, and targeted training for both residents and MSUs emerges as a key determinant of successful adaptation.

Conclusion: The fusion of both studies shows that hosting EU-trained residents is both demanding and enriching. Strengthening pedagogical training for supervisors, developing tailored support tools for residents educated abroad, and improving administrative and linguistic integration pathways appear essential to ensure high-quality training and facilitate successful incorporation into the French healthcare system.

ID 520 - Social Determinants of Osteoporosis Risk Using Easily Identifiable OSTA Scores Among Singaporean Rental-flat Residents

Riana-Marie GROSSKOPF

Irish Medical Council, Dublin, Irlande

Context: Continuity of care is a cornerstone of effective healthcare delivery, particularly for patients with complex or chronic conditions. Disruptions in healthcare continuity, often precipitated by frequent relocations, can lead to fragmented care, medication discontinuation, delayed interventions, and adverse health outcomes. Housing stability, a crucial social determinant of health, increasingly influences healthcare access and quality.

Methods: We report the case of a 39-year-old patient with asthma, migraine, long COVID/post-COVID syndrome, and a potential underlying autoimmune condition. Over a three-year period, the patient experienced multiple relocations within XXX (the city), resulting in intermittent healthcare engagement, medication interruptions, and delayed management of established conditions. These disruptions contributed to medical adverse events, raising questions about whether earlier identification of risk factors could have mitigated her negative health trajectory.

Originality: This case underscores a critical gap in current health systems, particularly as recent systematic reviews (published in BMJ, 2025) have highlighted the link between continuity of care and mortality. With housing insecurity affecting over 15 million Europeans and declining homeownership leading to rising rent and homelessness, the implications of care fragmentation are especially pertinent. This report emphasizes the tangible impact of frequent relocation on individual health and healthcare outcomes.

Lessons learned and future implications: The patient's siloed care trajectory reveals opportunities for early risk detection and intervention. Promoting continuity of care beyond immediate catchment areas—through integrated electronic health records, patient-held records, and

interdepartmental communication—could prevent adverse events. Enhancing systems to support highly mobile populations remains an urgent priority.

Discussion: This case highlights the unique challenges faced by mobile patients, including difficulties in maintaining medication adherence and timely access to care. Healthcare systems should adopt strategies such as comprehensive transfer documentation, telemedicine, and community health outreach to preserve continuity despite patient relocation.

Conclusion: Frequent relocations pose significant barriers to continuous care and adversely affect health outcomes. Proactive identification and tailored support for mobile patients are critical. Future research should focus on developing effective, scalable solutions to ensure care continuity in increasingly mobile populations.

ID 942 - Understanding how patients with chronic diseases shape their preferences: insights for general practitioners

Andrea POPPELIER, Clara BLANCHARD, Sonia DESCAMPS, Baptiste PROTEAU

Mspu Coeur De Saintonge, Saint Porchaire, France

Context: Since its creation in 2017, the Coeur de Saintonge Health Care Center (CSHCC) has brought together a multidisciplinary group of rural health professionals—general practitioners, nurses, pharmacists, midwives, speech therapists, and others—united by a commitment to serving the population of the XXX in southwest France. Building cohesion within such a diverse team requires continuous investment in communication, shared purpose, and supportive working conditions. In April 2024, the CSHCC conducted an extensive survey among its 42 professionals to better understand their daily reality: their work environment, challenges, and perspectives on key health priorities including chronic disease management, youth and elderly care, and vaccination. These findings informed a three-year strategic plan aimed at strengthening both population health and professional well-being.

Methods: The CSHCC created several multidisciplinary protocols designed to address priority health needs while fostering interprofessional collaboration: * ReCHUTE PA: a secondary-prevention program for patients over 60 reporting a fall. * Cica-Team: a mobile unit pairing a GP and a nurse trained in wound care, supported by a multidisciplinary advisory group. * Mémoire - Action: a therapeutic education program focused on preventing memory decline. * Vaccination Task Force: providing up-to-date vaccination information and organizing engaging, community-focused prevention activities. * COPD Task Force: an annual respiratory screening initiative for residents of the territory.

Originality: While the primary objective of these projects is to improve public health, their collaborative structure has had a notable secondary effect: enhanced communication and trust within the team. Professionals now seek one another's expertise more readily, even outside the formal scope of these programs.

Lessons learned and future implications: Regular feedback is essential. Sharing project outcomes reinforces professional motivation and acknowledges staff commitment. Building on this momentum, the CSHCC is now developing initiatives focused on supporting unpaid caregivers, in partnership with two neighboring health centers.

Discussion: Instead of producing a traditional written report, the CSHCC created a film showcasing its 2024 achievements—a rapid, engaging way to highlight results and celebrate team efforts. A key lesson emerged: working collectively toward a shared mission significantly reinforces team cohesion.

Conclusion: When thoughtfully presented, public health initiatives can become powerful tools for team building, strengthening both service delivery and professional cohesion.

ID 868 - Impact of a brief health education intervention on endocrine disruptor exposure in pregnant women and parents in primary care

Lisa-Maria GROSSER [(1)] , Sybille KRAUS [(1)] , Christian KOLLER [(2)] , Antonius SCHNEIDER [(1)] , Klaus LINDE [(1)] , Bernhard RIEDL [(1)]

(1) Institute Of General Practice And Health Services Research, Technical University Of Munich, Munich, Germany, Munich, Allemagne
(2) Tacke Koller Rechtsanwaltsgesellschaft Mbh & Co K, München, Deutschland, Munich, Allemagne

Context: The risk and actual experience of medical malpractice proceedings and their effects are very present in the medical trade press. Such proceedings can be settled in Germany through liability insurance, medical arbitration boards or court proceedings. There are no representative surveys in Germany on the extent to which general practitioners feel burdened by the risk of medical malpractice lawsuits.

Objectives: 1. To what extent does the risk of medical malpractice proceedings influence medical practice? 2. To what extent have physicians had personal experience with such proceedings? 3. To what extent were previous medical malpractice proceedings perceived as burdensome?

Methods: A four-page questionnaire was sent to a random sample of 2,000 registered general practitioners (general practitioners, general internists and family doctors) throughout Germany (with two reminders sent to those who did not respond). The evaluation was carried out using descriptive and inferential statistical methods.

Results: 1926 questionnaires were delivered; 640 doctors (average age 53±11 years, 48% female) returned a completed questionnaire (response rate 33%). Of these, 31% had experienced medical malpractice proceedings. Older age, a higher number of cases per quarter and male gender were associated with a higher probability of having experienced proceedings. 54% of participants with and 39% of those without liability experience (difference $p<0.001$) rated the influence of impending proceedings on their medical practice in general as strong or very strong. The influence was considered particularly strong in relation to information provision and documentation. Among the 197 general practitioners with personal experience of proceedings, the burden was most frequently perceived as strong or very strong in emotional terms (77%) and in terms of time (58%), while this was only the case financially for 6%.

Discussion: Although the response rate of 33% was significantly higher than for many other surveys of doctors in Germany, there is a risk that the responses are not fully representative of general practitioners in private practice due to a possible bias among those affected.

Conclusion: The risk and actual experience of medical malpractice proceedings appear to be a considerable burden for general practitioners and have a significant impact on their actions. This should prompt further investigation.

(8) gp, Medical Advisor Youth Clinics, Programme Director Of Continuing Education In Family Medicine Regionhälsan Region Västra Götaland, Gothenburg, Sweden, Gothenburg, Suède

Context: General practitioners often describe professional isolation and a lack of meaningful, peer-based education that reflects the true spirit of family medicine. In response, the Gothenburg branch of the Swedish College of General Practice (SFAM) created Allmänläkardygnet "The GP Day-and-Night", a 24-hour residential course by, for and with GPs. The aim was to rebuild identity, belonging and joy in the profession. The event, first held in 2019, now gathers 60–70 GPs from across Sweden each year in the same scenic venue near Gothenburg. Participants are divided into small, consistent groups to foster fraternity and equity in dialogue — every voice counts.

Methods: Planning starts a year ahead within the SFAM Gothenburg board, guided by participant feedback. The lunch-to-lunch programme includes four interactive sessions, reflective writing, creative breaks (music, dance), shared meals and evening social activities. All faculty are GPs; there is no external sponsorship. Strengths: peer-led authenticity, egalitarian structure, deep collegial immersion, humanistic focus. Limitations: the compressed 24-hour format can be demanding but intensifies engagement and connection.

Originality: The GP Day-and-Night differs from conventional CME by placing liberty, equity and fraternity at its core: liberty to explore professional dilemmas freely; equity among colleagues regardless of hierarchy; and fraternity through shared reflection and celebration. The course has revived professional enthusiasm locally — SFAM Gothenburg's membership has grown significantly since its launch.

Lessons learned and future implications: An inspiring first session and skilled group leaders are key to creating safety and openness. The continuity of place and rituals reinforces belonging and identity. The model's simplicity, lack of commercial influence and focus on shared humanity ensure sustainability.

Discussion: This peer-led, humanistic format illustrates how small-scale, reflective education can restore meaning, community and freedom within general practice.

Conclusion: The GP Day-and-Night offers a practical expression of liberty, equity and fraternity — values at the heart of primary healthcare — and a transferable model for sustainable professional renewal worldwide.

Corresponding author: Anna Holst, anna.holst@vgregion.se

ID 428 - Impact of the risk of medical malpractice proceedings on the work of registered general practitioners – a nationwide survey

Zejdush TAHIRI

Ubt, Gjilan, Kosovo

Context: Scientific information about the level of satisfaction of patients with general practice services is scant or nonexistent in Kosovo, and the exploration of such perspective would contribute to strengthen the PHC services in this country. Inspired from efforts to improve PHC in Kosovo and following the evidence that a well-established PHC is associated with lower costs, improved health outcomes and equity for the population, more efficient utilization of services and higher patient satisfaction

Objectives: Our aim was to assess the level and socio-economic correlates of satisfaction of PHC users (also referred to as patients' evaluation) in Kosovo, a transitional country in the Western Balkans.

Methods: A cross-sectional study was conducted in Gjilan region, Kosovo, including a representative sample of 1039 PHC users (87% response). Patients' evaluation of PHC services was assessed through EUROPEP, a 23-item instrument tapping different aspects of medical encounter

Results: Mean age of survey participants (56% females) was 41 ± 16 years. About 50% of the participants were satisfied with the overall quality of medical services, doctor–patient relationship and organization of care. Younger (below median age), urban and employed PHC users reported a significantly higher satisfaction level with the overall health encounter quality. Conversely, there were no sex or educational differences.

Discussion: The main findings of our survey suggest that fewer primary care users are satisfied with the general practice in Kosovo than in other European countries. The overall patient satisfaction was negatively associated with age and was significantly higher among urban residents and employed individuals. Younger age and employment status were significant correlates of higher satisfaction levels with either doctor–patient relationship, organization of care or the overall quality of medical encounter.

Conclusion: Considerably fewer PHC users in Kosovo were satisfied with the overall medical encounter compared with their European counterparts. This new and useful evidence may support health professionals and policy makers for improving the quality of PHC in Kosovo, a country struggling and mainstreaming all energies in order to get international recognition.

ID 753 - Antimicrobial Stewardship in General Practice: Management of URTIs

Sandip PRAMANIK, Callum MOYLE

Attenborough Surgery, Bushey, Royaume-Uni

Context: Primary care accounts for approximately 90% of all NHS contacts with 365 million appointments provided in 20231. An ageing population & a cost of living crisis exacerbated by the covid pandemic has resulted in an increased complexity of GP consultations The formation of a PCN complex care team provided a novel way of working to deal with complex & challenging patients to provide better continuity of care. By doing so the team could also reduce the strain that high intensity users have on the GP's & admin staff within our PCN thereby improving wellbeing but still offering appropriate patient centred care.

Methods: •An EMIS search was carried out looking at all patients on the PCN list size that had consulted the practice 15 times or more over a 3-month period. •A code was added onto their clinical record stating they were under the PCN complex care team. •A complex care protocol was created for both clinicians & admin staff to instruct how patients on the complex care register should be managed. Training offered to both clinical & admin staff. •Monthly MDT's have been held on the first Thursday of each month with full access to the clinical record with cases discussions of patients on the register.

Originality: The Attenborough complex care service is the first of its kind in the locality within the Hertfordshire area of the United Kingdom to develop a bespoke service incorporating doctors and allied health professionals in a team to manage patients of highly complex physical and mental health issues.

Lessons learned and future implications: •Quantifying the true impact of the complex care service can be difficult in terms of the number of appointments saved. •Reviewing and removing those from the register can be difficult •Replication of the model across other PCN;s across Herefordshire not so easy based on variation of GP numbers & allied helath professioanl staff.

Discussion: This initiative clearly demonstrates that improving continuity of care for complex and high-intensity patients significantly reduces the workload for family physicans.

Conclusion: This initiative clearly demonstrates that improving continuity of care for complex and high-intensity patients significantly reduces the workload on the PCN.

ID 709 - Connecting Primary Care: A Community Resource Map to Improve the Health of Vulnerable Populations

Kyoungwoo KIM [(1)] , Jae-Ho LEE [(2)]

(1) Inje University Haeundae Paik Hospital, Busan, Corée (République de)
(2) Seoul St. Mary's Hospital, College Of Medicine, The Catholic University Of Korea, Seoul, Corée (République de)

Context: Strong primary care is essential for achieving efficiency and equity in health systems by balancing health needs, services, and technologies . The health care environment continues to evolve with population aging , including increasing disease complexity and comorbidities, the introduction of new pharmaceuticals, advances in diagnostic and therapeutic technologies, and the growing subspecialization of medicine. These trends have driven a global rise in medical expenditures.

Objectives: To examine the association between having a usual source of care (USC) and healthcare expenditures among Korean adults, considering USC type and primary care attributes.

Methods: In this longitudinal study, data from 41,543 Korean adults aged ≥ 19 years were analyzed using the Korea Health Panel (2019–2022). We employed Hausman–Taylor panel regression methods while adjusting for the Charlson comorbidity index score, subjective health status, healthcare utilization, and demographic and socioeconomic factors. The primary variables included USC type (none, place only, and physician-based) and primary care attributes (comprehensiveness and coordination).

Results: Individuals with a physician-based USC exhibited a higher mean number of healthcare visits (21.78 in 2019 and 24.29 in 2022) but 13.1% lower adjusted expenditures, particularly when care was comprehensive and well-coordinated. Place-only USC had no significant cost advantage. In the elderly subgroup (≥ 65 years), these cost reductions were even more pronounced, with physicians demonstrating strong primary care attributes associated with up to 16.8% lower expenditures.

Discussion: Persistently low and unequal USC ownership, especially among vulnerable groups, highlights structural gaps in Korea's primary care

system and the need for reforms such as patient registration, quality-based incentives, and strengthened gatekeeping.

Conclusion: Physician-based USC, particularly when characterized by strong primary care attributes, is significantly associated with lower healthcare expenditures in Korea. Policy initiatives should prioritize enhancing the quality of primary care.

ID 653 - Identification of Distinct Physiological Stress Profiles in Healthy Adults via Adrenal Hormone and Heart Rate Variability-Based Clustering

Pemra CÖBEK UNALAN, Bengisu OLGUN, Saliha ŞAHIN

Marmara University School Of Medicine Department Of Family Medicine, İstanbul, Türkiye

Context: Well-being effect the whole life quality of a person and job related productivity of a physician.

Objectives: The study aims to explore how personal, job-related, and organizational factors influence the primary care physicians' well-being. Using Ryff's model, the study assessed the impact of burnout, social support, financial situation, and perceived social status on their mental health. explored

Methods: Data were collected from 423 family physicians across Turkey. The data collection tools included the 18-item Ryff Psychological Well-Being Scale, the Pines Burnout Scale, the MacArthur Scale of Subjective Social Status, and a researcher-developed questionnaire. Analyses were conducted using SPSS software.

Results: The mean age of participants was 44 years, indicating an overall experienced group of family physicians. Despite the presence of burnout, psychological well-being (PWB) scores were maintained at a moderate level. Nearly half of the participants reported financial difficulties; 44% stated that they had to cut down expenses or go into debt. Physicians with inadequate income had lower PWB scores and higher burnout scores. Most participants expressed hopelessness regarding future improvement in salary and benefits.Vacation was associated with higher PWB and lower burnout scores, whereas difficulties in finding a substitute physician during leave were linked to higher burnout. Physicians working in socioeconomically disadvantaged regions (SEGE 4 and SEGE 6) had lower PWB and social status scores and higher burnout levels. Coping strategies differed in their associations: walking was linked to significantly lower burnout scores; sleeping was associated with higher burnout; junk food consumption was also related to higher burnout. Approximately one-third of the participants reported using alcohol after stressful workdays, and alcohol consumption was positively associated with burnout but not with PWB. Physicians who reported receiving emotional support had lower burnout and higher PWB scores. Furthermore, pet ownership was positively associated with PWB.

Conclusion: The psychological well-being of family physicians is influenced by both personal and structural factors. The findings underline the need for supportive policies to enhance the well-being of family physicians in order to ensure sustainable primary healthcare delivery. Keywords: psychological well-being, family physicians, primary care, health professional, burnout

ID 639 - Severe Malnutrition Secondary to Superior Mesenteric Artery Syndrome: A Diagnostic Challenge in Primary Care

Colleen GRADY [(1)] , Dianne FORD [(2)] , Folasade ALADESUYI [(1)] , Sazzad Hossain KHAN [(2)] , Haley KAWAJA [(2)]

(1) Queen's University, Kingston, Canada
(2) Memorial University, St. John's, Canada

Context: This study explores family physician loneliness versus connectedness in their work environment. The loss of connectedness has been tied to negative impacts for physicians and is a potential contributor to eventual disillusionment in their careers. This study focuses on the workplace of family physicians in three provinces in Canada (ON, NS, NL) to examine work environment and the contributors to a decrease in wellbeing and connectedness. It is recognized that the need to feel connected within one's work environment is an inherent part of motivation and satisfaction.

Objectives: The overall goal of this study is to increase understanding of how and why the work environment for family physicians has affected their wellbeing, particularly their sense of belonging, value and career enjoyment.

Methods: An explanatory multiple case study, using mixed methods, which included an online survey and virtual semi-structured interviews conducted with practicing family physicians and family medicine residents. Additionally, document analysis for case-specific context was incorporated. Multiple case methodology allows identification of similarities and differences between cases.

Results: Data collection and analysis is currently ongoing; results will be available for presentation at the time of the conference. Thus far, approximately 150 survey responses have been received and 36 interviews conducted with 15-20 documents analysed. Preliminary analysis includes exploring the perspectives of family physicians in relation to their professional satisfaction, incidences of incivility in the workplace, social connectedness within family medicine, and response to stress.

Discussion: Loneliness among family physicians has been identified as very high and associated with both career burnout and depression. Violence and incivility are on the rise in healthcare, and early retirements and lack of interest in family medicine is significantly impacting the wellbeing of those that remain. Our findings will illuminate three unique cases that may inform action by provincial governments and medical associations to address the devaluation of family medicine, and which may lead to improved workplace satisfaction for a strengthened primary care system.

Conclusion: Our study encourages a different approach to addressing burnout and physician wellbeing as it is rooted in the premise that collegiality and connectedness in family medicine fosters motivation and career satisfaction.

ID 620 - Targeted antimicrobial susceptibility testing deployment: 2025 national survey by the French Regional Antibiotic Therapy Centers network

Rodeline TELFILS

Univ Rouen Normandie, Inserm, Normandie Univ, Aden Umr1073, Nutrition, Inflammation Et Axe Microbiote-Intestin-Cerveau, Rouen, France

Context: Gender-based and sexual violence (GBSV) is common in universities and may contribute to eating disorders (ED). Understanding this link is essential to support early detection, prevention, and to promote equality in student health.

Objectives: To analyze the association between GBSV and eating disorders among male and female university students in XXX.

Methods: A cross-sectional study was conducted in October 2024 among volunteer students at XXX. Participants completed an anonymous online questionnaire assessing their experiences of gender-based and sexual violence and their eating disorder symptoms. Eating disorders were screened using the SCOFF questionnaire and categorized using the Expali tool into restrictive disorders, bulimia, binge eating disorder, or other types. Logistic regression models were used to assess the association between GBSV and ED, adjusting for potential confounders.

Results: The sample included 563 students (433 women, 117 men), aged 18–30 years. Since the beginning of their studies, 51.7% (95% CI: 47.5–55.9) reported at least one form of gender-based or sexual victimisation, and 63.6% of them were polyvictims. Overall, 54.5% of students screened positive for an eating disorder, including 62.4% of women and 23.9% of men. Bulimia and binge eating disorder were the most common types across all genders. GBSV was significantly associated with the presence of an eating disorder (adjusted OR = 2.03; 95% CI: 1.40–2.93). The association differed strongly by gender: it was particularly pronounced among men (aOR = 12.1) compared with women (aOR = 1.76). Polyvictimisation further increased the likelihood of ED, with elevated risks for bulimia (aOR = 2.48; 95% CI: 1.52–4.03), restrictive disorders (aOR = 2.76; 95% CI: 1.08–7.08), and binge eating (aOR = 1.54; 95% CI: 0.77–3.06).

Discussion: Gender-based and sexual violence is strongly associated with eating disorders among university students, with the strongest effects observed among male students and polyvictims

Conclusion: These findings highlight the urgent need for equitable, trauma-informed care, targeted screening, and early intervention within university primary care services.

ID 419 - A descriptive study of a screening and vaccination program for newly arrived migrants between january 2022 and december 2023.

Jeong Uk BAI

Seoul National University Hospital, Seoul, Corée (République de)

Context: Depression is a major public health problem that worsens chronic disease outcomes and burdens patients, families, and healthcare systems. Although air pollution is a potentially modifiable environmental factor, existing studies report mixed results and underrepresent XXX primary care populations. Clarifying whether long-term exposure relates to depression in these settings can guide screening, counseling, and collaboration with public health efforts.

Objectives: The purpose of this study was to investigate the association between air pollution and positive depression screening in XXX adults.

Methods: This cross sectional study included 17,763 (9329 men; 8434 women) adults who underwent health checkups. For each participant, one-year-lagged average concentrations of particulate matter with an aerodynamic diameter of 2.5 µm or less (PM2.5) and 10 µm or less (PM10), nitrogen dioxide (NO2), sulfur dioxide (SO2), and carbon monoxide (CO) were assigned using the Community Multiscale Air Quality model. Depressive symptoms were assessed using Patient Health Questionnaire-2 (PHQ-2). Logistic regression estimated odds ratios for positive PHQ-2 screening and linear regression estimated changes in continuous PHQ-2 scores per interquartile range (IQR) increase in pollutant levels.

Results: A positive PHQ-2 screen occurred in approximately 13%. In single-pollutant models, PM2.5 was not associated with positive screening (odds ratio 0.99, 95% confidence interval 0.95 - 1.04) after adjusting for age, sex, season, body mass index, smoking, alcohol use, physical activity, diabetes mellitus, hypertension, and dyslipidemia. Estimates for PM10, NO2, SO2, CO were similarly null. For the continuous score, the adjusted beta coefficient of PM2.5 was -0.013 (95% confidence interval -0.04 - 0.01) per IQR increase. Results of other pollutants were similarly near zero. Multi pollutant models did not show significant association. Sex and age stratified results were nonsignificant.

Discussion: The lack of significant association may reflect unmeasured confounding variables, limited exposure contrast, or reverse causation whereby depressive symptoms reduce outdoor time and actual pollutant exposure. PHQ-2, while practical for large scale screening, may underestimate symptom burden compared with the nine-item instrument.

Conclusion: The results of this study showed no clear association between exposure to air pollutants and depression by PHQ-2 screening. Longitudinal studies including finer exposure resolution, repeated assessments, and richer psychosocial and neighborhood data are warranted.

ID 571 - Together for 24 Hours: Building Liberty, Equity and Fraternity Among General Practitioners Through Reflective Learning

Fabio FRANCHI QUAGLIATO, Ulisses REIS, Paula PIN, Laura TEIXEIRA, Eloisa CLEMENTE, Felipe LEITE, Marcelo DUTRA, Matheus MATOS, Soraya VARELLA

Centro Universitário Barão De Mauá, Ribeirão Preto, Brésil

Context: The homeless population is defined as a group of individuals living without regular conventional housing, in conditions of extreme poverty, with weakened or disrupted family ties, and facing significant barriers to accessing health care services. This limited access contributes to a lifetime prevalence of mental disorders in this group that exceeds 70%.

Objectives: The aim of this study was to describe the level of anxiety among people experiencing homelessness and to analyze their engagement with Primary Health Care (PHC) services in the city of XXX.

Methods: A total of 47 homeless individuals were interviewed. Participants first completed a sociodemographic questionnaire, followed by the Mini-SMD instrument for screening mental disorders, including anxiety. Those who screened positive for anxiety were subsequently assessed using the GAD-7 scale, which classifies anxiety as minimal, mild, moderate, or severe.

Results: Among the participants, 24 (51%) screened positive for anxiety. Of these, 4 (17%) had minimal anxiety, 3 (12.5%) mild, 9 (37.5%) moderate, and 8 (33%) severe. Regarding their connection to health care services, 23 individuals reported having been seen at least once by a PHC team, while only 7 had ever been attended by a Family Health Team (FHT). Among the 24 individuals with anxiety, 14 had previously been attended by a PHC team, and only 4 by an FHT, indicating limited access to continuous and comprehensive health care.

Discussion: The findings reinforce the high prevalence of anxiety symptoms among the homeless population, which is associated with factors such as social marginalization, substance

abuse, and limited access to continuous and comprehensive health care. Moreover, the data highlight a fragile connection between this population and primary care services, hindering the implementation of person-centered and ongoing care. The lack of a strong and sustained engagement with PHC compromises continuity of care and the effectiveness of mental health interventions.

Conclusion: Therefore, the study underscores the urgent need for public policies that strengthen access to and engagement with PHC among homeless individuals, through strategies tailored to their specific needs, ensuring comprehensive, continuous, and person-centered care.

Patient-centered care

ID 569 - Understanding The Drivers Behind What Matters When Treating Gastro-Oesophageal Reflux Disease – A Discrete-Choice Experiment

Ana Beatriz MEIRA MAGALHÃES

Usf Paredes De Coura, Ponte De Lima, Portugal

Context: Alzheimer's disease and related dementias (ADRD) affect over 60 million people worldwide, resulting in significant emotional burden on informal caregivers. Existing mobile health (mHealth) applications largely fail due to non-personalized content (83% focus on generic education), lack of scientific validation (only 20% reviewed by specialists), and insufficient practical support.

Methods: This project proposes an integrated, user-centric mHealth application. The system will follow an evidence-based model, offering stage-adapted (mild, moderate, advanced) cognitive stimulation and psychosocial support. Personalization employs Explainable Artificial Intelligence (XAI) via SHAP algorithms to justify content recommendations , adapting to the user profile. Validation is secured through partnerships with neurologists and psychologists. Expected Outcomes include a 25% reduction in caregiver stress (based on Zou et al., 2024) and a 15–20% increase in patient cognitive performance. Strengths: validated information and dynamic personalization (vs. 6% of apps using AI). Limitation: reliance on external partnerships for updates.

Originality: The innovation lies in simultaneously resolving the three primary mHealth failures: non-personalization (via XAI and stage adaptation), lack of scientific validation, and excessive theoretical focus (via practical tools and external referencing to resources like Alzheimer Portugal).

Lessons learned and future implications: Key lessons emphasize the necessity of scientific validation and XAI transparency for user trust and adherence. Future challenges involve overcoming high post-launch abandonment rates (common in 71% of apps) and integration with the National Health System (SNS) for effective referral.

Discussion: The project is feasible due to reduced development costs (using open-source platforms) and strategic partnerships (e.g., university hospitals). This model encourages a shift towards validated, stage-adapted digital support in primary care settings, offering a superior alternative to generic applications.

Conclusion: This project provides a robust, evidence-based digital solution with strong potential to mitigate caregiver burden and improve patient cognitive outcomes. The next steps involve prototyping and executing clinical trials to measure real-world impact.

Context: Psychosocial vulnerability plays a central role in suicidal behavior among patients with bipolar disorder.

Objectives: This study aimed to identify psychosocial factors associated with suicide attempts and to emphasize their relevance for family medicine practice.

Methods: We conducted a cross-sectional analytical study including 281 patients diagnosed with bipolar disorder who were hospitalized over a six-year period. Data were collected on childhood trauma, family psychiatric history, risk behaviors,

and comorbid personality disorders. Patients were divided into two groups according to the presence or absence of a lifetime history of suicide attempts. Univariate and multivariate analyses were performed to identify factors associated with suicide attempts.

Results: A history of suicide attempts was significantly associated with childhood abuse or neglect (36.6%, $p < 0.001$), engagement in risk behaviors such as runaway episodes or self-harm ($p < 0.001$), presence of comorbid personality disorders ($p < 0.001$), and a family history of suicide or suicide attempts ($p = 0.01$). Notably, several of these psychosocial factors were present before the onset of bipolar disorder and could be identified outside specialized psychiatric care.

Discussion: Psychosocial vulnerability was strongly associated with suicide attempts among patients with bipolar disorder. Factors such as childhood trauma, family history of suicidal behavior, and early risk behaviors often precede the clinical diagnosis and may be detected during routine consultations in primary care. These findings highlight the importance of integrating systematic psychosocial assessment into family medicine to improve early identification of patients at risk.

Conclusion: Incorporating structured psychosocial screening into routine family medicine practice may strengthen early suicide prevention and reduce suicidal behaviors among patients with bipolar disorder

ID 459 - Eating Disorders and Gender-Based and Sexual Violence Among XXX University Students

Théo GILSON [(1)] , Cécile BOUR [(2)] , Jean DOUBOVETSKI [(2)]

(1) Université Cote D'azur, Nice, France
(2) Cancer Rose, Paris, France

Context: Breast Cancer screening has an unclear benefit/risk ratio according to the litterature. We have developed a Decision Aid (DA) for women at average risk of breast cancer to facilitate shared medical decision-making and informed choices regarding their participation in organized breast cancer screening.

Objectives: This DA is intended to provide balanced information on the benefits and harms of screening, based on french data. This study aims to assess whether the tool is clear and comprehensible, reduces decision-making conflicts, and improves knowledge of the benefits and harms of screening mammography.

Methods: We conducted a pragmatic study based on a before-and-after reading of the DA involving 88 women aged between 47 and 74 years with an average risk of breast cancer. Participants, recruited by their healthcare provider or through social networks, were invited to complete a pre-reading and a post-reading questionnaire. Decisional conflicts were assessed using the SURE questionnaire

Results: The DA was rated helpful at 4.51/5, pleasant at 4.10/5, and understandable at 4.43/5. After reading the DA, more women report being sufficiently informed. (82.9% vs. 69.2, $\chi2$ (1) = 8.17, $p < .004$, $n = 72$). Based on the SURE questionnaire, women show fewer decision-making conflicts after reading (27.4% gain in absolute difference of "yes" answers; $\chi2 = 27$, $p < .001$, $n = 85$). 66.7% of respondents consider that the DA will help them decide on their participation. 41.7% declared they intend to have a screening mammogram within the next two years.

Discussion: Our results align with other similar studies, notably on reducing decision-making conflicts and improving informed choice. This DA is validated and could be used on a larger scale. The effect on participation to screening is unclear, and requires further studies. We suggest to generalize a DA as a complement to invitation letters.

Conclusion: The DA is clear, understandable, and easy to use for most women. It is perceived as more informative than the standard information. It helps reduce decision-making conflicts by increasing women's knowledge of the benefits and harms of screening, improving their confidence and feeling better supported in their choices.

ID 373 - A study of environmental health integration in primary healthcare workers in the region of "XXX" in 2024

Zi Xuan NG, Lay Hoon GOH

National University Of Singapore, Singapore, Singapour

Context: Osteoporosis is a rising public health burden in rapidly ageing Asian societies, including Singapore, where hip fracture rates rank among the highest globally. The role of social determinants and

healthcare access in shaping osteoporosis vulnerability remains under-explored despite robust characterisation of biological risk. Understanding these relationships may support more equitable screening and prevention strategies in primary care.

Objectives: We examined osteoporosis risk association with socioeconomic and healthcare utilisation factors in Singaporean rental-flat residents.

Methods: A cross-sectional study was conducted among rental-flat health screening participants in October 2025. The Osteoporosis Self-Assessment Tool for Asians (OSTA) was used for rapid stratification of osteoporosis risk. Descriptive analyses were followed by ordinal logistic regression to assess associations between OSTA category, socioeconomic position (SEP) and healthcare utilisation proxies, adjusting for gender and comorbidities.

Results: Among 116 participants (50.9% female; mean age 64.0±10.8), the median OSTA score was -1.88 (IQR -4.52 to -0.6), yielding 40.8% low, 41.7% intermediate, and 17.5% high-risk classifications. As expected, higher OSTA risk was associated with older age and lower weight, but no significant associations were observed across lifestyle factors or living arrangements. In adjusted models (R2=0.133), Pioneer/Merdeka Generation (PG/MG) healthcare payment benefit awareness was a good predictor of medium/high OSTA risk (p=0.016,aOR=4.11,95%CI=1.35-13.6). Higher-tier Community Health Assistance Scheme (CHAS) cardholders demonstrated higher odds of medium/high OSTA risk (p=0.009,aOR=2.56,95%CI=1.29-5.37). Enrolment into long-term health monitoring programmes (HealthierSG) was not significant (p=0.412,aOR=0.670).

Discussion: Reported SEP gradients align with regional evidence linking socioeconomic disadvantage to greater osteoporosis vulnerability via multimorbidity and constrained preventive behaviour access. Higher subsidised-service utilisation with greater chronic disease burden may explain elevated OSTA risk given underlying illness-driven patterns of healthcare engagement. Non-significant effects of long-term health monitoring may indicate potential gaps in sustained longitudinal preventive care engagement in at-risk individuals. These findings reflect established literature suggesting that structural disadvantage and illness-driven healthcare utilisation shape osteoporosis risk trajectories in ageing populations.

Conclusion: OSTA-based screening may identify patterned socioeconomic disparities in osteoporosis risk, thus integrating social risk indicators into community and primary care workflows may support more equitable and proactive bone-health management. Future qualitative work is warranted to explore mechanisms shaping osteoporosis vulnerability across diverse health systems.

ID 391 - From symptom to precise diagnosis: the utility of echocardiography in transforming cardiovascular practice within primary care.

Gilles CORNELIS

University Of Louvain, Brussels, Belgique

Context: Taking patient preferences into account is a recognised quality criterion in the care of patients with chronic diseases. However, the concept of preference remains insufficiently defined in medicine, and little literature explores how patients themselves understand what a preference actually means.

Objectives: The aim of this ongoing research is to examine how patients develop their preferences in relation to their experience of chronic illness and the care they receive, with particular attention to the potential role of the general practitioner.

Methods: To date, we have conducted 12 semi-directed individual interviews with patients with chronic diseases from diverse backgrounds. The transcripts are currently being analysed according to the principles of the grounded theory.

Results: Preliminary results show that the experience of chronic illness and healthcare influences several key elements involved in the formation of patient preferences, including risk perception, trust in healthcare professionals, and the management of medical information. Chronic illness thus creates a unique ecosystem in which patients' preferences take shape and acquire specific meanings, such as maintaining a sense of identity or experiencing safety within the care they receive. Across the different contexts in which preferences are formed, general practice appears to be both an accessible and appropriate setting—owing to its holistic approach, longer consultation times, and integration of information from various specialists—for supporting the development of

patients' preferences, as well as for facilitating their expression, whether actively or passively.

Discussion: Our study challenges the often-cited, simplistic view of the role of medical information in shaping patient preferences. The construction of patient preferences requires patients to balance a critical stance towards the care they receive with a sufficient level of trust in their doctors. General practitioners might support this balance by providing a trusted space in which patients can challenge their treatment and the assessments of other doctors involved in their care.

Conclusion: The findings of this research will provide general practitioners with practical insights into how to engage with patients with chronic diseases in constructing their preferences regarding their care.

ID 306 - Association between air pollution and depression screening in XXX adults

Isabelle ROZIER, Nassira YAHIA

Département De Médecine Générale D'amiens, Université De Picardie Jules Verne, Amiens, France

Context: The prenatal period and the first two years of life (the first 1000 days) represent critical windows of susceptibility and exposure to various environmental factors. Studies have shown associations between prenatal exposure to certain chemicals and adverse effects on pregnancy outcomes, newborn health, and long-term child development.

Objectives: The aim of this study was to evaluate the impact of a brief 5-minute health education intervention on endocrine disruptors, delivered by healthcare professionals, on changing the behaviors of pregnant women at any stage of pregnancy and parents of children under two years of age, three months after receiving the information.

Methods: This is a multicenter quantitative interventional study conducted between March 2024 and July 2024. The required sample size was 53 participants. The primary outcome was the difference in the number of correct responses before and after the health education intervention. Participants were recruited from a maternity ward, a private midwifery practice, and a maternal and child health center in XXX. Participants were surveyed about their knowledge of endocrine disruptors and their daily habits via a questionnaire, then received a brief prevention intervention on endocrine disruptors using an informational brochure. Participants were contacted three months later to assess the impact of the intervention using the same questionnaire. The study was approved by an ethics committee.

Results: A total of 63 women were recruited. This study shows a statistically significant increase in questionnaire scores between baseline (Day 0) and three months (Mean before = 3.56; Mean after = 4.88; 95% CI [0.98; 1.68] and p = 2.164e-10), with an improvement of 1.32 points.

Discussion: The strength of the study lies in its adequate statistical power and reproducibility of the intervention. Limitations include the refusal of fathers to participate in the questionnaire, which may affect the generalizability of the findings to both parents. Additionally, the study only assessed the immediate impact of the intervention, with no long-term evaluation of its effectiveness.

Conclusion: The intervention resulted in a significant improvement in participants' knowledge and behavior regarding endocrine disruptor exposure. These findings suggest that brief health education sessions in primary care can effectively change behaviors associated with environmental health risks.

Chu Nantes, Nantes, France

Context: A preventive health consultation dedicated to newly arrived migrants (NAM) has been settled within a departmental vaccination and screening center.

Objectives: This study aims to describe the characteristics of patients seen during the consultation and the pathologies detected among them.

Methods: A descriptive, retrospective, single-center study included NAM patients aged 18 years and older who have been seen between 01/01/2022 and 31/12/2023. The data were anonymized and extracted from the department's softwares.

Results: A total of 95 adults were included in the study, predominantly male (74%, n=70/95), with a median age of 26 years [23; 33], from West Africa (55%, n=52/95), French-speaking (61%, n=58/95), and arrived in France the prior year (95%, n=90/95). They faced socioeconomic obstacles : unstable administrative status (97%, n=77/79), housing difficulties (83%, n=79/95), and no social security coverage (87%, n=83/95). Two thirds had at least one known medical history (67 %, n=64/95), 33% had tobacco or alcohol use (n=31/95) and 65% reported experiencing violence (n=52/79). The most frequent clinical problems were dental pathologies (67 %, n=37/58), overweight (43 %, n=36/83) and abdominal problems (25 %, n=20/80). More than half exhibited symptoms of psychological distress (67 %, n=40/66), including sleep difficulty (35 %, n=23/66), anxiety and depression (27 %, n=18/66), or serious disorders (4 %, n=4/66). Numerous infection diseases were detected: chronic hepatitis B virus infection (16 %, n=15/95, by HBsAg+ serology), schistosomiasis and strongyloidiasis (27 %, n=19/70 and 6 %, n=3/52 respectively), syphilis (4 %, n=3/92), and bacterial STIs (3 %, n=2/95). No HIV (n=0/95) or HCV (n=0/94) infections were found. Among the tuberculosis screening performed (n=63/95, by chest X-rays), 4 patients were referred for abnormality (6%, n=4/63). Almost all had vaccination update (92 %, n=88/95), and all were referred to health and/or social professionals (n=95/95).

Discussion: The characteristics of our population align with findings from studies conducted in other French departments, demonstrating the complexity involved in their healthcare provision.

Conclusion: This study confirms significant vulnerability and medical needs among newly migrated people, particularly in the period following their arrival. The numerous diagnoses support the importance of early access to care including infectious diseases sreening and vaccination with a medico-psycho-social management.

ID 349 - Motivations and barriers to nature prescribing among general practitioners (GPs) in XXX

Cristina LOGHINA [(1)] , Marilena CALIMAN [(2)]

(1) M F, Secuieni, Roumanie
(2) M F, Bacău, Roumanie

Context: In the last 20 years, globally, more children received the first dose of measles/mumps/rubella (MMR) vaccine. However, in most countries, the second dose coverage is lower than 95%, the coverage with two doses World Health Organization recommended for herd immunity. This is leading to outbreaks and putting vulnerable groups at risk.

Methods: The purpose of the study was to compare the rate of vaccination between a disadvantaged rural community and an urban community and to identify ways to improve the situation. We collected data about measles/mumps/rubella administration, in a population-based retrospective cohort study from January 2005 to December 2024, using our general practice database. The two population groups investigated had similar number of children (600). The obtained data were compared with the national and global rates. Other collected data were related to the educational level of parents who refused vaccination, and their economic status.

Originality: A similar decrease in the vaccination rate with the second dose of MMR was observed in both studied groups, although there were differences in economic level between rural and urban communities.

Lessons learned and future implications: Routine vaccination and immunization campaigns are vital for closing coverage gaps and controlling outbreaks. Family doctor's persuasion, insistence, social/community worker involvement, acceptance at vaccination without an appointment have been successfull in convincing hesitant parents. There remains a percentage of reluctant parents for whom we have not found yet the right solution.

Discussion: In both groups investigated, the mobility of young families (emigration or within the country), the impact of social media , the pandemic trauma, lower trust in doctors and the influence of religious representants were identified as reasons for non-vaccination. In both groups parents who refused MMR vaccination had relatively equal proportions of higher education, secondary education and lower education. In both groups the children were admitted for vaccination without an appointment.

Conclusion: A similar decrease in the vaccination rate with the second dose of measles/mumps/rubella was observed in both rural and urban group. Integrated public policies with multidimensional approach, concerted and specific

actions must be taken in order to increase the rate of vaccination and control the outbreaks.

ID 332 - Adopting an integrated approach to address the holistic needs of patients in a primary care network using a complex care team to improve continuity of care

Anaïta TZOURIO

Faculté Paris Saclay, Paris, France

Context: In 2023, nearly 40 million people were living with HIV worldwide. Access to antiretroviral therapy (ART) has significantly improved but poor adherence to treatment remains a major public health issue. Few studies have focused on adherence in HIV, and none have explored the link between having a primary care physician and adherence to antiretroviral treatment. Yet, the primary care physician is often the doctor who knows the patient and their psychosocial environment best.

Objectives: The goal of this study is to test the hypothesis that having a primary care physician influences adherence among people living with HIV.

Methods: This is a retrospective, observational, single-center study based on the hospital records of 119 patients followed for HIV at the hospital of Saint-Denis. Adherence was defined as having a viral load of < 20 copies/ml. Additional data were collected (related to the patient, HIV status, treatment, etc.). The association between viral load and the presence of a primary care physician was analyzed using univariate and multivariate logistic regressions.

Results: Among the 119 patients included, 26.1% had a detectable viral load. In the group without a primary care physician, 42.4% had a positive viral load, compared to 19.8% in the group with a primary care physician. This difference was statistically significant (p = 0.022). The adjusted odds ratio (OR) for having a detectable viral load in patients without a primary care physician was 5.60 (1.69–21.05). No other variable was associated with a positive viral load.

Discussion: Our findings show that having a declared primary care physician is strongly associated with better adherence to antiretroviral therapy, reflected by higher rates of undetectable viral load. This association persisted after adjustment for demographic and social factors, suggesting an independent effect. Patients without a declared physician more often faced social and administrative vulnerability, which may hinder access to continuous care. Despite these differences, no other clinical or behavioral variables explained adherence.

Conclusion: In our study, having a declared primary care physician was statistically associated with better adherence to antiretroviral treatment. These results highlight the central role of primary care continuity and patient–physician communication in supporting adherence among people living with HIV.

(2) Usf Bom Porto, Uls Santo António, Porto, Portugal

Context: Ensuring medication safety in elderly patients with multimorbidity requires clear communication and consistent medication reviews, especially when using high-risk drugs such as methotrexate. Methotrexate toxicity is well described, presenting with acute kidney injury, myelosuppression, hepatotoxicity, mucositis and multiorgan failure. Renal impairment, caused by dehydration, comorbidities or chronic NSAID use, reduces drug clearance and increases toxicity risk. Medication reconciliation includes ensuring an accurate medication list and confirming any changes in prescription, dose or formulation, thereby reducing errors.

Methods: We describe the case of a 73-year-old woman with severe rheumatoid arthritis, multimorbidity and polypharmacy who developed severe methotrexate toxicity due to unintentional taking both oral and subcutaneous formulations following a recent therapeutic change. She presented to a primary care unit with several weeks of anorexia, vomiting, progressive fatigue, weight loss and newly developed mucosal bleeding. Blood tests revealed new-onset pancytopenia, acute kidney injury and hepatic abnormalities, prompting urgent referral to the emergency department. During evaluation, it was confirmed that she had unintentionally continued oral methotrexate while initiating the subcutaneous formulation, in the context of chronic NSAID use, leading to hospitalization.

Originality: This case highlights the central role of communication and medication reconciliation in preventing adverse drug events. A misunderstanding during a formulation switch led to severe methotrexate toxicity, amplified by multimorbidity, polypharmacy and NSAID use, illustrating how common clinical factors may converge into avoidable harm.

Lessons learned and future implications: This case reinforces the need for systematic medication review and for ensuring that patients fully understand therapeutic changes. Adapting communication strategies to individual needs and taking time to confirm treatment understanding are essential steps in promoting safety.

Discussion: Multiple interacting factors contributed to the severe presentation of methotrexate toxicity, underscoring the importance of clear communication at every therapeutic transition. Primary care teams, due to their continuous and longitudinal patient contact, are uniquely positioned to detect misunderstandings early and to manage polypharmacy with caution, including chronic NSAID use or complex medication regimens.

Conclusion: Clear communication and medication reconciliation are essential to prevent avoidable harm during medication changes, particularly in polypharmacy patients. Family medicine plays a key role in ensuring safe therapeutic transitions.

(1) Department Of General Practice, Faculty Of Medicine And University Hospital Carl Gustav Carus, Dresden, Allemagne
(2) Institute For General Practice, Faculty Of Medicine, Leipzig University, Leipzig, Allemagne

Context: Prescriptions for levothyroxine (LTX) are increasing worldwide, although the number of cases of overt hypothyroidism as the primary indication has not risen (Khandelwal&Tandon 2012). Based on current knowledge, subclinical hypothyroidism (SH) does not require drug treatment. The German guideline for general practitioners (GPs) states that LTX withdrawal can be considered in cases of SH. No structured LTX deprescribing strategy has yet been established in primary care.

Objectives: What are the barriers and enablers for deprescribing LTX in general practice?

Methods: In the DELTA-PIA research project, we used a qualitative, participatory approach involving GPs and patients with SH or experience with discontinuing medication. From March to October 2024, we conducted seven focus group interviews and three workshops with 17 GPs and 17 patients. The focus groups examined and prioritized barriers, facilitators, and conditions for deprescribing in routine care, while the workshops jointly developed a strategy for LTX deprescribing. Focus groups were recorded and transcribed, and workshops documented using whiteboards. The collected material was analyzed using qualitative content analysis.

Results: The participating GPs identified key enablers for LTX deprescribing: reducing side effects, depathologizing patients with SH, and lowering medication burden. They also noted major barriers, including anticipated patient resistance, short-term increase in workload, potential financial losses, and conflicts with other healthcare professionals. Patients reported feeling insufficiently informed, and medication changes often caused skepticism, uncertainty, and concerns about symptoms. At the same time, they described potential benefits such as improved quality of life, fewer side effects, and savings in time and costs.

Discussion: Our study showed a general willingness among GPs and patients to discontinue LTX, but there are barriers that at both the physician and patient levels that make deprescribing processes in primary care challenging (Doherty et al. 2020, Moretti et al. 2024). It requires a change in mindset among all stakeholders in order to initiate deprescribing processes.

Conclusion: Reflecting barriers and enablers, a structured deprescribing strategy is required that incorporates all identified conditions and provides a decision-making tool for handling the identified barriers.

(2) Barts And The London School Of Medicine And Dentistry, London, Royaume-Uni

Context: Antimicrobial resistance has been identified as one of the ten greatest threats to global public health. Consequently, governments around the world have developed guidance around antimicrobial stewardship. As part of this, healthcare professionals are urged to perform audits that inform prescribing practices and improve patient care. This work was carried out in response to this call to action.

Objectives: First, to evaluate the prescribing practices of five doctors at XXX against the XXX's guidelines on Management of Acute Coughs and Sore Throats. Second, to identify areas of improvement. Third, to propose recommendations for the betterment of patient care at XXX.

Methods: Data on all consultations conducted by five doctors at XXX across three weeks was accessed via the electronic patient record system. All information required to evaluate prescribing practices against national antimicrobial guidelines was also recorded. Data processing was performed on Microsoft Excel.

Results: 856 patients were seen in the three weeks, with 80 (9.3%) of them presenting with URTI symptoms. Acute Cough 71% were managed appropriately. Of the prescriptions given, 73.9% had the correct antibiotic, dose, and length. Sore Throat 40% were managed appropriately. It was impossible to determine propriety in 33.3% of the cases. Of the prescriptions given, 82% had the correct antibiotic, dose, and length. Advice and Safety-Netting 50% of patients were given self-care advice and 87.5% were safety-netted.

Discussion: The majority of acute cough cases are managed appropriately. An unexpected issue arose when evaluating sore throat patients. Guidelines stipulate that Centor scores should be calculated to determine whether antibiotics are warranted, but scoring was not possible in 33.3% of cases as relevant symptoms were not appropriately documented. The results also imply that only half of patients are advised on symptom management. However, in-person observations of consultations confirm that virtually all patients are appropriately examined and counselled.

Conclusion: The main issue identified was not inappropriate management, but poor documentation. However, it must be acknowledged that there is a dirth in the most crucial resource of all: Time. With each appointment restricted to 10 minutes, thorough documentation is nigh impossible. This is a deeper structural challenge the nation's strained healthcare system must face.

(2) Visfo Health, Huddersfield, Royaume-Uni

Context: Proton pump inhibitors (PPIs) are extensively prescribed due to the widespread diagnosis of gastro-oesophageal reflux disease (GORD). However, common overutilisation raises concerns about inappropriate prescribing; prompting interest in holistic management and deprescription strategies.

Objectives: This study aimed to quantify UK healthcare professionals' (HCPs) and patients' preferences in GORD management, and to identify attributes perceived as influencing quality of care.

Methods: Attributes were derived from qualitative data gathered through focus groups, to develop a discrete-choice experiment (DCE) which was administered via online survey. 45 HCPs and 29 patients chose between paired hypothetical GORD management scenarios. Preferences were modelled using multinomial conditional logit with effects coding. Marginal rates of substitution were calculated to quantify trade-offs.

Results: A holistic treatment plan that included both PPIs and lifestyle modification was strongly preferred over PPI monotherapy by both HCPs ($\beta = 0.632$, $p < 0.001$) and patients ($\beta = 0.364$, $p < 0.001$). Lifestyle modification was non-significantly preferred over PPI monotherapy by patients ($\beta = 0.101$, $p = 0.106$), who also preferred the on-demand use of PPIs over daily treatment ($\beta = -0.214$, $p = 0.135$); Both patients and HCPs had a significant negative view of information being delivered by

pamphlets rather than by a HCP (patients: β = -0.254, p = 0.020, HCPs: β = -0.170, p = 0.032). There was no preference whether information was delivered by a doctor or a pharmacist. HCPs demonstrated a non-significant preference for a more structured follow-up plan (β = 0.067, p = 0.320). Symptom severity was a key driver for both HCPs and patients, with no patient preference over paying out-of-pocket for treatment (β = -0.023, p = 0.013).

Discussion: The desire for a holistic treatment plan suggests patient frustration at being prescribed daily PPIs indefinitely. HCP preference for a structured follow-up suggests a willingness to accept additional appointments to better support this multi-modal patient treatment.

Conclusion: This study highlights the value of holistic, clinician-led treatment for GORD patients. HCPs favour structured follow-ups, while patients prefer lifestyle modification and symptomatic treatment. This highlights the need for the development of a multi-modal treatment approach, integrated with self-care.

ID 193 - Empowering communities through peer support: strengthening integrated primary care for people with type 2 diabetes and hypertension in XXX

Juliette ZIMMERMANN [(1)] , Orphyre FOSTIER [(2)]

(1) Alliance Santé Planétaire, Paris, France
(2) Faculté De Médecine, Maïeutique Et Sciences De La Santé, Lille, France

Context: There is a growing recognition that nature exposure is beneficial for human health. Nature prescription programs have been implemented in many countries to address the high burden of non-communicable diseases. Nature prescription is a low-cost health intervention which can easily be used on its own or as a complement to drug treatments. Prescribing nature has several co-benefits, such as encouraging pro-environmental behaviours. However, in France, nature prescriptions are not routine in primary care practice.

Objectives: To identify enablers and barriers surrounding nature prescriptions in primary care in XXX, France.

Methods: For this qualitative study inspired by grounded theory, we interviewed GPs (n=11) in XXX. Purposive sampling was applied until data sufficiency was reached.

Results: Facilitators to nature prescribing include awareness of the health benefits of nature, regular personal contact with nature, interest in an alternative to medication, acknowledgment of the important role played by GPs in planetary health, easy, free and local implementation, and positive feedback from patients. Some participants questioned the existence of scientific evidence of the benefits of nature. Some of them feared side effects such as increase in skin cancers. Lack of time, lack of peer support and acceptance of the value of nature as a support for wellbeing, difficulties to access nature for some patients were reported as barriers. Participants identified a need for accessible theoretical resources, policy statements and national guidelines. They would benefit from help by other care givers and an easier access to nature for their patients.

Discussion: The strength of this study lies in addressing an unexplored topic in France and promoting planetary health; limitations include the low number of participants, variable interview depth, and challenges inherent to qualitative analysis. Findings align with international literature.

Conclusion: The uptake and delivery of nature prescriptions is influenced by the prescriber's own relationship with nature, personal experience and/or knowledge of the benefits of nature for health. To lower the barriers we highlighted, it is critical that governments and local decision-makers support the greening of communities especially in urban areas, and that official guidelines be drawn up. Broader public health campaign would allow nature prescription to deploy.

(2) Unidade De Saúde Familiar Nova Salus, Vila Nova De Gaia, Portugal

Context: Oropharyngeal carcinoma includes HPV-associated and non-HPV–associated tumors, the latter classically linked to tobacco and alcohol. HPV-16 is now a major cause of tonsillar carcinoma, with incidence rising in Western countries since the early 2000s. HPV-mediated tumors have distinct epidemiological, clinical, and prognostic features and are potentially preventable through vaccination. In primary care, persistent unilateral otorhinolaryngological symptoms are common and may mask malignancy, emphasizing the importance of clinical vigilance and timely referral.

Methods: A 57-year-old woman, a former smoker with prior tonsillectomy, presented to a walk-in consultation with six months of persistent unilateral odynophagia, cervical swelling, and recent fever. She denied dysphagia and dysphonia. Examination revealed right-sided tonsillar asymmetry with uvular deviation, soft palate edema, ulceration with exudate, and a painful submandibular lymph node. Given symptom chronicity and laterality, urgent referral to otorhinolaryngology was initiated. Cervicothoracic computed tomography (CT) identified a 31 × 18 mm neoplastic lesion in the right tonsillar fossa with locoregional invasion and a suspicious retropharyngeal lymph node. Histopathology confirmed squamous cell carcinoma. Positron emission tomography (PET) confirmed staging as cT4 cN1 cM0. Immunohistochemistry showed diffuse p16 overexpression, consistent with HPV-mediated carcinoma. The main strength of this case was timely referral from primary care; its limitation was the nonspecific presentation, which could have delayed diagnosis. The measurable outcome was prompt multidisciplinary evaluation and initiation of radical concomitant chemoradiotherapy.

Originality: This case demonstrates HPV-16–mediated tonsillar carcinoma presenting with subtle, prolonged unilateral symptoms after prior tonsillectomy. It highlights the decisive role of primary care in early detection and the link to prevention through vaccination.

Lessons learned and future implications: Persistent unilateral otorhinolaryngological symptoms warrant careful reassessment and a low threshold for referral. Family physicians play a central role in HPV vaccination advocacy, the most effective strategy to reduce the future burden of HPV-mediated oropharyngeal cancer.

Discussion: The rising incidence of HPV-16–associated tonsillar carcinoma challenges traditional risk-based diagnostic approaches in general practice. Integrating symptom duration, laterality, and focused examination with awareness of evolving epidemiology reduces diagnostic delay.

Conclusion: This case highlights the pivotal role of family physicians in early recognition of HPV-mediated tonsillar carcinoma and long-term cancer prevention through universal HPV vaccination, with significant implications for individual and population health.

ID 697 - Prevalence of Sexual Addiction in Three Primary Care Multidisciplinary Practices in Northern France

Christina SOMMERAUER [(1)] , Katrin BUREK [(1)] , Alexandra SCHMIDT [(1)] , Dorothea DEHNEN [(2)], Alessia DEHNEN [(2)], Jürgen IN DER SCHMITTEN [(2)], Horst Christian VOLLMAR [(3)], Bernd HEMMING [(4)], Achim MORTSIEFER [(1)] , Christine KERSTING [(1)]

(1) Institut Für Allgemeinmedizin Und Ambulante Gesundheitsversorgung (iamag), Universität Witten/ Herdecke, Witten, Allemagne,
(2) Institut Für Allgemeinmedizin, Medizinische Fakultät Universität Duisburg-Essen, Essen, Allemagne,
(3) Abteilung Für Allgemeinmedizin (am Rub), Ruhr-Universität Bochum, Bochum, Allemagne,
(4) Deutscher Hochschulverband Physician Assistant E.v., Köln, Allemagne

Context: Primary care provision particularly in rural areas is already under pressure and will face increasing challenges in the future in XXX. Physician assistants (PAs) have the potential to support the delivery of comprehensive and high-quality primary care. The project “Physician Assistants meet primary care” (PAAM) investigates to which extent PAs can contribute to primary care teams and alleviate the workload of general practitioners (GPs). However, their deployment in GPs’ practices remains largely unfamiliar in XXX. To ensure optimal

interprofessional collaboration, participating practices are supported throughout the entire 18-month intervention period through structured and regular coaching. This includes on-site coaching sessions, online training modules and online quality circle meeting.

Objectives: Identification of most essential topics for practice team coaching to ensure the effective integration of PAs into general practice teams.

Methods: The PAAM project is a randomized controlled trial assessing patient-related safety parameters (primary endpoint) and acceptance and cost-effectiveness (secondary endpoints). General practices randomized into the intervention group receive a PA and structured coaching. To assess the needs for the coaching, a literature review was conducted, along with a workshop involving general practices, PAs and the Association of Statutory Health Insurance Physicians of XXX, as well as three online workshops with practice teams experienced in working with PAs.

Results: Experiences from GP practices with prior PA implementation have shown that, with proper organization, PAs can take on a wide range of tasks in primary care and be effectively integrated into the team. The following key topics for practice team coaching to support PA integration were identified: 1. Interprofessional collaboration and task allocation/roles within the team 2. Patient communication 3. Liability and delegation 4. Financing and billing 5. Benefits for the practice team

Discussion: Successful integration requires early and clear communication. Delegation and billing issues are common challenges that can be addressed by coaching. PAs can relieve GPs and strengthen primary care, but they require structured onboarding and ongoing support.

Conclusion: Clear role allocation, effective communication and knowledge of delegation and billing are crucial for successful PA integration. Targeted coaching is intended to optimally prepare practice team for effective collaboration.

Context: Adequate prenatal care is a cornerstone of primary health care and a key determinant of maternal and neonatal outcomes. In Brazil, prenatal care is delivered within primary care, making territorial analyses relevant. The ratio of prenatal consultations to live births (PNC/LB) serves as a proxy for service provision intensity, accessibility, and equity when analyzed alongside socioeconomic vulnerability indicators.

Objectives: To analyze the spatiotemporal distribution of the prenatal consultations-to-live births ratio in São Paulo State from 2008 to 2024 and its spatial association with socioeconomic vulnerability, as measured by the São Paulo Social Vulnerability Index (IPVS).

Methods: This ecological spatiotemporal study included all municipalities in São Paulo State. Annual data on prenatal consultations and live births were obtained from national health information systems, and the PNC/LB ratio was calculated for each municipality (2008–2024). Socioeconomic vulnerability was measured using the IPVS, an ordinal index based on income, education, household composition, and life cycle characteristics. Choropleth maps were produced, spatial autocorrelation was assessed using Global Moran's I, and local patterns were identified through bivariate LISA analysis.

Results: The PNC/LB ratio showed marked spatial heterogeneity throughout the study period. The analysis revealed persistently lower ratios in municipalities located in historically vulnerable regions, including the Vale do Ribeira, coastal areas, and the western portion of the state.. Global Moran's I indicated significant positive spatial autocorrelation ($I = 0.08$; $p < 0.001$). LISA analysis identified high–high clusters corresponding to structurally consolidated urban regions and low–high outliers, revealing local fragilities within otherwise well-performing regional networks. The bivariate analysis demonstrated that municipalities

with higher socioeconomic vulnerability consistently had the lowest prenatal care ratios.

Discussion: The spatial correspondence between vulnerability and reduced prenatal care provision underscores structural inequities in primary health care delivery. The persistence of low ratios in vulnerable areas suggests that service expansion has not overcome historical disadvantages. Conversely, municipalities with adequate provision despite high vulnerability may indicate local resilience, effective primary care organization, or targeted policies, reinforcing the relevance of territorially informed planning.

Conclusion: Prenatal care in São Paulo State is uneven and shaped by socioeconomic vulnerability. Integrating spatiotemporal indicators with vulnerability measures supports equity-focused decisions and targeted interventions.

Context: Acute scrotal pain requires urgent differential diagnosis between testicular torsion—a surgical emergency with a 6-hour window for testicular salvage—and inflammatory conditions such as epididymo-orchitis. In XXXX public health system (XXX), diagnostic delays of 24-48 hours are common due to limited radiology access. Point-of-care ultrasound (PoCUS) could enable time-sensitive decision-making in resource-limited primary care settings, yet implementation remains highly incipient in XXXX family medicine.

Methods: A 54-year-old male presented to a primary care unit XXXXX in XXXXX with acute unilateral scrotal pain. Considerable swelling and tenderness raised suspicion for testicular torsion. A medical student with focused PoCUS training performed bedside scrotal ultrasonography using a handheld Butterfly iQ3 device, under supervision, assessing key sonographic markers: testicular edema, parenchymal texture, intratesticular and epididymal blood flow, and the whirlpool sign. Findings demonstrated preserved testicular architecture bilaterally, robust intratesticular arterial flow, and absence of the whirlpool sign, ruling out testicular torsion within less than 10 minutes. An anechoic fluid collection consistent with reactive hydrocele secondary to epididymo-orchitis was identified. The patient received outpatient conservative management.

Originality: While PoCUS expands in XXXX emergency and intensive care settings, primary care application remains scarce. This case demonstrates portable ultrasound integration into routine XXX primary care practice, notably achieving diagnostic capability with a medical student operator using minimal training and affordable portable technology.

Lessons learned and future implications: PoCUS reduced diagnostic time from 24-48 hours to under 10 minutes—critically placing diagnosis within the therapeutic window for testicular torsion. A medical student with extracurricular training successfully performed risk stratification using a handheld device, preventing unnecessary emergency referral while ensuring patient safety. This dramatic time reduction could fundamentally restructure primary care capabilities for time-sensitive presentations and adequate risk stratification in resource-limited settings.

Discussion: Implementation barriers include lack of formalized curricula in medical schools/residency programs, equipment costs, and absence of XXX reimbursement policies. However, minimal training requirements, decreasing device costs, and demonstrated clinical utility support PoCUS integration into XXXXX primary care training programs.

Conclusion: Point-of-care ultrasound enables rapid, objective decision-making within critical therapeutic windows. Minimal training with portable technology can reduce diagnostic timelines from days to minutes, transforming primary care capabilities in resource-limited settings.

ID 2055 - Sex Differences in the Pharmacological Profile of Older Adults with Risky Alcohol Consumption

Buğra BALCAN, Sümeyra Nur DELIKKAYA, Vildan MEVSIM

Department Of Family Medicine, Dokuz Eylul University Faculty Of Medicine, Izmir, Turkey, İzmir, Türkiye

Context: In winter, headache and dizziness are frequent primary care complaints and are often treated as viral illness or "tension." Carbon monoxide (CO) exposure can mimic benign conditions and requires rapid recognition and preventive counseling.

Methods: A 39-year-old man attended a FHC with two days of headache, nausea, and marked fatigue. He had no fever, cough, or focal neurological symptoms. Examination was normal; oxygen saturation was 98% on room air. During history taking, the physician asked whether anyone at home had similar symptoms and about the heating source. The patient reported that his wife and two children had morning headaches that improved outdoors and that they used a coal stove in a poorly ventilated apartment. Despite normal SpO2, CO poisoning was suspected. The family was advised to leave the home immediately, ventilate the house, and avoid re-entry until assessed. The patient and symptomatic relatives were referred urgently to the emergency department. COHb levels were elevated, and they received oxygen therapy without complications. At FHC follow-up, a short home-safety intervention was delivered: chimney and stove maintenance, adequate ventilation, avoiding indoor charcoal use, and recommendation of CO alarms. Written safety-netting was provided for recurrence symptoms and emergency warning signs.

Originality: A single targeted question about shared household symptoms changed the diagnostic pathway.

Lessons learned and future implications: Primary care should routinely ask "Who else is ill at home?" in winter complaints. Normal pulse oximetry does not rule out CO exposure.

Discussion: CO poisoning remains under-recognized due to non-specific symptoms. Early suspicion plus household counseling can prevent recurrent exposure.

Conclusion: In FHC practice, clustered household symptoms with indoor heating should trigger immediate CO precautions and urgent referral.

(2) Linköping University, Kalmar, Suède
(3) Gothenburg University, Vaxjo, Suède

Context: Hip fractures are a significant cause of disability and mortality among older women. Age-related decline in physical function, balance, and skeletal fragility are established risk factors, whilst the long-term impact of commonly used medications on hip fracture risk remains unclear. Medication-related fracture risk can inform primary care prevention strategies.

Objectives: To investigate associations between baseline regular medication use and subsequent hip fracture risk over long-term follow-up in a cohort of women aged 70 years and older.

Methods: Observational cohort study of a population-based hip fracture prevention project in rural southern Sweden. 1248 women 70-100 years old were recruited in 2001; the intervention group of 434 women provided comprehensive baseline regular medication data in a baseline survey. Hip fracture outcomes were ascertained through the radiology department´s electronic health record fracture registries from 2002 to 2025. Cox proportional hazards regression models estimated hazard ratios for time to first hip fracture associated with >20 medication classes, adjusting for age and concurrent medication use. Follow-up time was determined until first hip fracture, death, or end of study.

Results: Among 414 women with complete baseline medication information (mean age 79.4 years), 85 (21%) sustained a hip fracture during follow-up. Increasing age was associated with higher hip fracture risk (HR per year 1.08 (1.03-1.13), p<0.001). After age and co-medication adjustment, most medication classes showed no significant associations with hip fracture. Use of benzodiazepines was associated with increased hip fracture hazard (HR 3.1 (1.2-7.8), p=0.017), whereas antidepressant use was associated with a reduced hazard (HR 0.3 (0.1-0.8) p=0.012). Corticosteroid use showed borderline association with increased hazard, and bisphosphonate use showed borderline association with reduced hazard.

Discussion: Age emerged as the dominant determinant of hip fracture risk. Given the number of medication classes examined and the absence of Bonferroni correction for multiple testing, the association observed for antidepressants should be interpreted with caution and may reflect chance findings or confounding by indication.

Conclusion: In this cohort of older women, baseline medication use had limited impact on long-term hip fracture risk, whereas increasing age showed a clear association with fracture risk.

ID 290 - Low muscle mass, obesity, and cause-specific mortality in cancer patients: A nationwide cohort study

Alperen KÜÇÜKUYSAL, Sümeyra Nur DELIKKAYA, Vildan MEVSIM

Dokuz Eylul University, Faculty Of Medicine, Department Of Family Medicine, Izmir, Türkiye

Context: In primary care, depression frequently presents with somatic rather than psychological symptoms, particularly among young adults and men. Nonspecific complaints such as fatigue or musculoskeletal pain may obscure the underlying diagnosis and delay appropriate management. This challenge is amplified in busy family medicine settings, where consultations often prioritize biomedical explanations. Early recognition of depression with somatic presentation is essential to prevent unnecessary investigations and prolonged patient distress.

Methods: A 23-year-old man presented to a family medicine clinic with diffuse muscle pain and requested a medical leave certificate. He reported no additional physical complaints. Medical history and physical examination revealed no evidence of acute or chronic somatic disease, and no inflammatory, neurological, or metabolic red flags were identified. Given the absence of an organic explanation, a brief psychosocial assessment was conducted. The patient described ongoing conflict with his mother and unresolved emotional distress related to childhood parental separation and being raised by his grandmother. He reported persistent rumination and low mood but had never sought mental health care. The Patient Health Questionnaire-9 (PHQ-9) was administered, yielding a score of 19, consistent with moderately severe depression. He was referred to a psychiatric outpatient clinic. At follow-up three weeks later, antidepressant treatment had been initiated. The patient reported improved mood, marked reduction in muscle pain, improved daily functioning, and no further need for work leave.

Originality: This case illustrates how depression in young men may present predominantly with somatic symptoms, masking the underlying psychiatric condition, and demonstrates the diagnostic value of structured mental health screening in primary care.

Lessons learned and future implications: Routine psychosocial inquiry and validated tools such as PHQ-9 should be considered in patients with unexplained musculoskeletal pain to reduce diagnostic delay and unnecessary interventions.

Discussion: Resolution of somatic symptoms following antidepressant treatment supports the close interaction between psychological distress and physical complaints. Childhood adversity may increase vulnerability to depression, highlighting the importance of longitudinal, patient-centered care in family medicine.

Conclusion: Primary care physicians play a key role in identifying depression presenting with somatic symptoms. Early recognition, appropriate screening, and timely referral can significantly improve outcomes.

Context: Recent epidemiological studies using non-invasive methods to screen for liver fibrosis in adults have reported a marked increase in the of metabolic-associated steatotic liver disease (MASLD). MASLD is mainly associated with overweight and obesity. The prevalence of overweight and obesity in children and adolescents has also increased rapidly in recent years. Transient elastography (TE) with controlled attenuation parameter (CAP) is a non-invasive diagnostic method for determining fibrosis and steatosis, but little is known about its applicability in the pediatric population. Magnetic resonance imaging with proton density fat fraction (MRI-PDFF) is highly accurate for the diagnosis of steatosis, but its complexity and cost makes unavailable.

Objectives: 1) To assess the prevalence of significant liver fibrosis (Liver Stiffness Measurement (LSM) ≥6.5 kPa) using TE, and that of MASLD (≥225 dB/m) using CAP in children and adolescents. 2) To determine the optimal cut-off points of the CAP to achieve maximum concordance with the MRI-PDFF findings in the diagnosis of mild, moderate and severe MASLD.

Methods: This is an observational, descriptive, cross-sectional, population-based study conducted in Barcelona. Subjects aged ≥9 to ≤16 years were included. Eligible participants were recruited from educational and primary care centers. Sociodemographic, anthropometric, and clinical data were collected, blood samples were obtained, TE with CAP was performed. Participants with abnormal findings on TE or CAP were referred for MRI-PDFF.

Results: 1,380 participants, 52.3% boys, 67.7% under 13 years old, with a prevalence of overweight and obesity of 14.3%. The prevalence of steatosis and fibrosis was 14.8% and 4.1%, respectively, according to TE and CAP. 78.9% consumed soft drinks and 84.2% fast food. Only 31.4% followed an optimal diet.

Discussion: MASLD is a multifactorial disease in which hepatic steatosis may progress over time to stetohepatitis and, in some individuals, to liver fibrosis, and then, promoting cirrhosis and hepatocellular carcinoma. In this pediatric cohort, a notable prevalence of MASLD and fibrosis was observed, with low rates of overweight and obesity together with high consumption of sugar-sweetened beverages and fast food. Moreover, we are currently analysing MRI scan to correlate them with the obtained data.

Conclusion: Early detection and prevention of MASLD in children and adolescents are needed.

ID 461 - Analysis of the Associations among Obesity, Exercise Habits, and Weight Change with Colorectal Cancer Risk: Utilizing Customized Data from the National Health Insurance Service

Nicola KAVANAGH, Naomi SMITH

Manor Road Surgery, Dublin, Irlande

Context: Benzodiazepines are primarily used for short periods to manage acute anxiety, addiction, agitation and neurological disorders (The Medical Council 2025). Long term use poses risks to patient safety (HSE 2021). A candidate advanced nurse practitioner (cANP) led initiative was formulated in our practice, aiming to reduce repeat prescribing of benzodiazepines in general practice, in an area of social deprivation.

Methods: The programme was led by a cANP. The project involved a two audit cycle with intervention in one local general practice. Patient sample was gathered by convenience sampling with data gathered retrospectively via a GP management system. The first audit cycle was completed between November 2024- January 2025 and second 6 months subsequently, between August2025-October 2025. Results: 107 patients were included in the programme with 73% being female and 27% male. The mean age of patients was 60. A 35% reduction in overall repeat prescribing was seen after 6 months with 13.4% fully weaned. 79.5% of patients reduced their monthly benzodiazepine prescription, showing a very high level of positive engagement with the process.

Originality: Although GP engagement in benzodiazepine reduction has been enhanced by national recommendation to protect patient safety, no data pertains to these initiatives being led by ANPs in Ireland (The Medical Council of Ireland 2025). The ANP-led model allowed longer consultations, more frequent review, and a consistent therapeutic relationship, contributing to improved engagement.

Lessons learned and future implications: 1. Display of services offered by cANP reduced role ambiguity. The visible clinical leadership reinforced the suitability of the GP cANP role to lead complex medicines optimisation projects, with measurable benefits for patient safety. 2. Understanding of Health literacy of patients in an area of social deprivation. In-person communication helped to provide education in an accessible format.

Discussion: This audit demonstrates the feasibility of empowering advanced nursing staff to tackle this significant issue. The role of the ANP encompasses leadership and the increasing position in primary care promotes the multidisciplinary approach to improving patient outcomes.

Conclusion: Engaging a whole practice approach ensured all patient facing clinicians and patients could provide a unified approach to consistent messaging, improving patient confidence in their primary care team.

Context: Alcohol consumption among older adults has increased over recent decades. In parallel, medication use also rises as the population ages. Interactions between alcohol and medications may interfere with drug efficacy and increase the risk of adverse effects. Moreover, biological sex differences exist in both alcohol and drug metabolism, which may influence clinical outcomes.

Objectives: This study aimed to assess sex differences among older adults with risky alcohol consumption, taking into account medication use, comorbidity, and hepatic biomarkers.

Methods: A cross-sectional, descriptive, multicentre study was conducted in adults aged over 64 years. A total of 455 participants with risky alcohol consumption, defined according to the criteria of the Spanish Programme of Preventive Activities and Health Promotion, were included. Sociodemographic and clinical variables, medication prescriptions, and blood analytical parameters were collected.

Results: Of the 455 participants, 41% were women, with a mean age of 71 years. The mean weekly alcohol consumption was 8.4 ± 8.3 standard drink units (SDU). Overall, 71.2% of participants were taking at least one medication. The most commonly prescribed medications were antihypertensives (62%). Significant sex differences were observed ($p \leq 0.01$). Men showed a higher use of antidiabetic drugs (24%), anticoagulants (8%), and nitrates (4%), whereas women more frequently used anxiolytics (35%), non-steroidal anti-inflammatory drugs (22%), and antidepressants (18%). Significant differences between men and women were also found in the De Ritis ratio and gamma-glutamyl transferase levels ($p \leq 0.01$).

Discussion: Although risky alcohol consumption was more prevalent among men, women showed a higher overall medication use. Pharmacological profiles differed by sex: women more frequently used medications related to pain and mental health management, while men more often received drugs aimed at the prevention or treatment of cardiovascular diseases.

Conclusion: In this sample, a high proportion of older adults with risky alcohol consumption were simultaneously undergoing pharmacological treatment. This coexistence may lead to clinically relevant alcohol–drug interactions with potentially serious consequences. The identification of sex-related differences in comorbidities, medication prescription patterns, and analytical biomarkers highlights the importance of incorporating a sex perspective in both research and clinical practice.

ID 1957 - When odynophagia points to more than benign disease: recognising HPV-mediated tonsillar carcinoma in primary care

Antonio Augusto FARIA CASTRO, Henrique CARVALHO GOES, Larissa FERREIRA HORTA, Pedro DIRCEU ORTOLANI JÚNIOR, Paula PERCHES ORTOLANI

São Leopoldo Mandic Araras, Araras, Brésil

Context: Obesity is a chronic, multifactorial, and prevalent disease with deleterious effects on health and a direct impact on healthcare system costs. Glucagon-like peptide-1 receptor agonists (GLP-1 RAs) have proven effective in the treatment of obesity, promoting significant weight loss and metabolic improvements. However, discontinuation of these medications frequently leads to weight regain, raising concerns about the sustainability of the achieved benefits and the need for long-term maintenance strategies.

Objectives: To describe the impact of GLP-1 RA therapy discontinuation on weight regain and the pathophysiology mechanisms involved.

Methods: A literature review was conducted using articles indexed in the PubMed database with the keywords: “GLP-1 receptor agonists,” “Weight regain,” and “Drug withdrawal.” The descriptor “GLP-1 receptor agonists” was combined with the other keywords, with filters applied to include only studies published in the last five years. Article selection was based on abstract screening. Studies that aligned the central theme and met the objectives were selected for full-text analysis.

Results: Clinical trials demonstrate that discontinuation of glucagon-like peptide-1 receptor agonist (GLP-1 RA) therapy is associated with significant weight regain. In the STEP 1 trial, participants receiving semaglutide 2.4 mg regained approximately 66% of the weight lost one year after treatment discontinuation. Similarly, in the SURMOUNT-4 trial, participants switched from tirzepatide (10 or 15 mg) to placebo experienced a mean 14% weight regain after 52 weeks, whereas those who continued treatment achieved an additional 5.5% reduction in body weight, highlighting the importance of treatment continuation for weight maintenance.

Discussion: Weight regain following GLP-1 RA discontinuation is a consistent, clinically relevant phenomenon. From a pathophysiological perspective, this effect is attributed to reversal of central appetite and satiety regulation and loss of delayed gastric emptying. These changes increase caloric intake and reduce energy expenditure, contributing to worsening metabolic parameters, including glycemic and lipid profiles, after therapy withdrawal.

Conclusion: Weight regain after discontinuation of GLP-1 RAs is associated with the reversal of mechanisms modulated by these drugs, including increased appetite, reduced satiety, and return of accelerated gastric emptying. Therefore, it’s essential to integrate pharmacological therapy with sustained behavioral strategies, such as nutritional reeducation and regular physical activity, to maintain the benefits achieved.

ID 1959 - "When One Suffers, All Endure”: A Family’s Shared Journey with Pancreatic Cancer

Norlly ALBA

Southern Isabela Medical Center, Santiago City, Isabela, Philippines

Context: Dermatologic complaints are among the most common reasons for consultation in primary care. In adolescents, chronic skin conditions may have significant psychosocial implications, particularly when lesions resemble sexually transmitted infections (STIs). This case was encountered in a Family and Community Medicine outpatient clinic in a government tertiary hospital in the Philippines. A sexually active adolescent male presented with a long-standing rash associated with marked anxiety related to sexual health, highlighting the intersection of dermatologic, mental health, and preventive care concerns commonly faced in primary care.

Methods: This is a descriptive clinical case report of an 18-year-old male with a three-year history of nonpruritic erythematous annular rashes on the back. A comprehensive primary care assessment was conducted, including medical, sexual, and psychosocial history, physical examination, and mental health screening. Diagnostic investigations included KOH skin scraping, complete blood count, HIV antigen testing, syphilis serology (RPR/VDRL), and hepatitis B screening. Management consisted of oral and topical antifungal therapy, health education, reassurance, counseling on safe sexual practices, and follow-up after two weeks.

Originality: Although tinea corporis is a common dermatologic condition, this case is distinctive because it mimicked an STI and resulted in repeated testing and severe health-related anxiety. The case demonstrates the value of integrating dermatologic care with psychosocial assessment and adolescent-centered counseling within a family medicine framework.

Lessons learned and future implications: Family physicians should recognize that dermatologic

symptoms may trigger psychological distress, particularly among adolescents and sexually active populations. Early reassurance, accurate diagnosis, and mental health screening can reduce unnecessary investigations and repeated consultations. Strengthening adolescent-friendly services and integrating psychosocial care into routine primary care consultations may improve outcomes and patient trust.

Discussion: Despite classic clinical features of tinea corporis, the patient's anxiety necessitated comprehensive STI evaluation and counseling. Addressing both biomedical and psychosocial dimensions was essential to effective management, reflecting the holistic principles of family medicine.

Conclusion: This case illustrates how common dermatologic conditions can have significant psychosocial consequences. A comprehensive primary care approach—combining accurate diagnosis, preventive education, and mental health support—can effectively address both physical disease and emotional distress in adolescents.

ID 776 - Integrating Infrastructure and Workflow Planning for Pandemic Preparedness in Primary Care Clinics

Li MA, Taihong LV, Shan ZHOU, Yanli LIU

Department Of General Medicine, Beijing Tiantan Hospital, Capital Medical University, Beijing, Chine

Context: The Cardiovascular-Kidney-Metabolic (CKM) syndrome, formally proposed by the American Heart Association in 2023, underscores the interdependent relationships among cardiovascular dysfunction, chronic kidney disease, and metabolic risk factors. While biomarkers are pivotal for early detection, risk stratification, and prognosis in CKM, a comprehensive synthesis of evidence linking diverse biomarkers to its multifaceted clinical outcomes is currently lacking.

Objectives: To systematically evaluate available evidence on biomarkers associated with CKM progression, summarize their predictive utility, and inform the development of stratified risk prediction models for this syndrome.

Methods: In accordance with the PRISMA 2020 statement, we conducted a systematic search of PubMed, Cochrane Library, Embase, and Web of Science for observational studies published between October 2023 and September 1, 2025. Eligible studies examined associations between routinely measurable biomarkers and clinical outcomes including CKM stage progression, cardiovascular disease, stroke, renal function decline, and mortality. Study selection, data extraction, and quality appraisal were performed independently by two reviewers. Pooled hazard ratios with 95% confidence intervals were derived using random-effects meta-analysis.

Results: Fifty-one studies, encompassing over 30 biomarkers, were included. Meta-analysis indicated that the Systemic Inflammation Response Index was consistently and positively associated with both all-cause and cardiovascular mortality. Among insulin resistance-related markers, the Triglyceride-Glucose index and its composite derivatives showed positive associations with incident cardiovascular disease, stroke, and heart disease, with composites integrating central obesity measures exhibiting enhanced predictive performance. The Estimated Glucose Disposal Rate demonstrated protective associations across all evaluated endpoints. Additional markers, including measures of arterial stiffness, cumulative atherogenic index, and relative muscle mass, were also significantly linked to distinct clinical outcomes.

Discussion: Findings support inflammation–insulin resistance–visceral adiposity as central CKM pathways. However, heterogeneity, observational designs, and residual confounding limit causal inference. Standardized assays and prospective cohorts should validate multi-marker panels to improve CKM risk classification and clinical implementation.

Conclusion: Systemic inflammation, insulin resistance, and visceral adiposity represent core pathophysiological pathways in CKM syndrome initiation and progression. Integrating multidimensional biomarkers—spanning inflammatory, metabolic, body composition, and cumulative exposure domains—can clarify subgroup-specific applicability, optimize biomarker panels, and advance their translation into individualized clinical decision-making frameworks.

ID 996 - Exploring the Lived experience of Shared care Between Primary and Hospital care in People Living with HIV.

Nikki Rose AGCAOILI

Southern Isabela Medical Center, Santiago City, Isabela, Philippines

Context: Methamphetamine ("shabu/ice") use disorder remains a major public health and primary care challenge in the Philippines, commonly linked with poverty, stigma, disrupted family systems, and legal consequences. In rural settings, patients frequently enter care through crisis events rather than early screening, with coexisting non-communicable diseases (NCDs) and psychosocial distress often under-recognized. Family physicians are uniquely positioned to provide continuity, coordinate intersectoral support, and facilitate family healing during rehabilitation and community reintegration.

Methods: This is a family case report of a 46-year-old male from Barangay Sandiat West, San Manuel, Isabela, Philippines with severe methamphetamine use disorder. Data were derived from primary care consultations at the Rural Health Unit (RHU), rehabilitation records, and follow-up interviews. Risk assessment used ASSIST; family assessment employed the Patient-centered, Family-focused, Community-oriented (PFC) matrix and family tools (SCREEM, Family APGAR, genogram, and ecomap). Care involved multidisciplinary inpatient rehabilitation and structured family counseling using Catharsis–Education–Action (CEA), complemented by a multi-sectoral reintegration plan with the Municipal Health Office, MSWDO, barangay officials, PNP, PESO, and PAO.

Originality: This case illustrates a "continuum-of-care" model where the family physician bridges facility-based rehabilitation and community-based aftercare, integrating NCD management, relapse prevention, and family systems work while coordinating local governance and legal-sector partners—an approach highly relevant to resource-limited municipalities implementing CBDRPs.

Lessons learned and future implications: Recovery was strengthened by: (1) early primary care screening after legal apprehension, (2) proactive management of NCD comorbidities (hypertension, dyslipidemia, gout), (3) structured family assessment and counseling to rebuild trust, and (4) coordinated reintegration supports (monitoring, livelihood linkage, transport and social assistance). Gaps observed included inconsistent CBDRP engagement prior to rehabilitation, limited trained personnel, and persistent stigma. Strengthening standardized CBDRP modules, integrating routine screening in RHUs, and ensuring aftercare pathways with livelihood support may reduce relapse risk.

Discussion: The patient's use escalated from occupational fatigue and psychosocial stress to daily dependence, resulting in family estrangement and repeated legal involvement. After 12 months of inpatient rehabilitation, he returned to his mother's home, engaged in farm labor, and sustained abstinence. Family functioning improved (Family APGAR mean 6.2 to 7.6 within four months), indicating gradual relational repair.

Conclusion: Severe methamphetamine use disorder requires holistic, long-term care that addresses medical comorbidity, family dynamics, and community reintegration. Family physicians can sustain recovery by providing continuity, family-focused counseling, and intersectoral coordination, even within imperfect systems where relapse remains a constant risk.

ID 1421 - Strengthening Primary Care Through Policy: Collaborative Efforts to Secure EU Specialty Status for Family Medicine

Christina SOMMERAUER [(1)] , Katrin BUREK [(1)], Alexandra SCHMIDT [(1)], Dorothea DEHNEN [(2)], Alessia DEHNEN [(2)], Jürgen IN DER SCHMITTEN [(2)], Horst Christian VOLLMAR [(3)], Bernd HEMMING [(4)], Achim MORTSIEFER [(1)], Christine KERSTING [(1)]

(1) Institut Für Allgemeinmedizin Und Ambulante Gesundheitsversorgung (iamag), Universität Witten/ Herdecke, Witten, Allemagne
(2) Institut Für Allgemeinmedizin, Medizinische Fakultät Universität Duisburg-Essen, Essen, Allemagne(3) Abteilung Für Allgemeinmedizin (am Rub), Ruhr-Universität Bochum, Bochum, Allemagne
(4) Deutscher Hochschulverband Physician Assistant E.v., Köln, Allemagne

Context: Primary care provision particularly in rural areas is already under pressure and will face increasing challenges in the future in XXX. Physician assistants (PAs) have the potential to support the delivery of comprehensive and high-quality primary care. The project "Physician Assistants meet Allgemeinmedizin [primary care]" (PAAM) investigates to which extent PAs can contribute to primary care teams and alleviate the workload of general practitioners (GPs). However, their deployment in GPs' practices remains largely unfamiliar in Germany. To ensure optimal interprofessional collaboration, participating practices are supported throughout the entire 18-month intervention period through structured and regular coaching. This includes on-site coaching

sessions, online training modules and online quality circle meeting.

Objectives: Identification of most essential topics for practice team coaching to ensure the effective integration of PAs into general practice teams.

Methods: The PAAM project is a randomized controlled trial assessing patient-related safety parameters (primary endpoint) and acceptance and cost-effectiveness (secondary endpoints). General practices randomized into the intervention group receive a PA and structured coaching. To assess the needs for the coaching, a literature review was conducted, along with a workshop involving general practices, PAs and the Association of Statutory Health Insurance Physicians of Westphalia-Lippe, as well as three online workshops with practice teams experienced in working with PAs.

Results: Experiences from GP practices with prior PA implementation have shown that, with proper organization, PAs can take on a wide range of tasks in primary care and be effectively integrated into the team. The following key topics for practice team coaching to support PA integration were identified: 1. Interprofessional collaboration and task allocation/roles within the team 2. Patient communication 3. Liability and delegation 4. Financing and billing 5. Benefits for the practice team.

Discussion: Successful integration requires early and clear communication. Delegation and billing issues are common challenges that can be addressed by coaching. PAs can relieve GPs and strengthen primary care, but they require structured onboarding and ongoing support.

Conclusion: Clear role allocation, effective communication and knowledge of delegation and billing are crucial for successful PA integration. Targeted coaching is intended to optimally prepare practice team for effective collaboration.

ID 1826 - Health communication with Pomeranian patients: an experience report

Muataz KHALID

Primary Health Care Corporation (phcc), Doha, Qatar

Context: Anabolic–androgenic steroid (AAS) misuse is an emerging global public health concern increasingly encountered in primary care. Amateur athletes often use AAS for body image enhancement rather than competitive advantage, influenced by social media and gym culture. Presentations are frequently subtle, with cardiometabolic and endocrine abnormalities that delay diagnosis and increase long-term risk. Recent studies estimate AAS misuse prevalence among amateur athletes at 3–6%, highlighting its growing impact on primary care.

Methods: A 24-year-old male amateur bodybuilder presented with fatigue, mood swings, and acne. He disclosed six months of unsupervised testosterone and nandrolone cycles purchased online. Blood pressure was 150/95 mmHg; examination revealed acne over the chest and back and testicular atrophy. Laboratory results showed HDL 0.7 mmol/L, LDL 4.8 mmol/L, ALT 78 U/L, and suppressed LH/FSH. Management included motivational interviewing, education on health risks, cessation planning, structured monitoring (lipid profile, liver function tests, and hormones), and referral to endocrinology and psychology. The case was analyzed using a reflective, evidence-informed approach informed by current literature.

Originality: This case highlights AAS misuse outside elite sport, driven by social media and gym culture, where healthcare engagement is often delayed. It underscores the general practitioner's role in opportunistic screening and harm-reduction counselling within routine consultations.

Lessons learned and future implications: Primary care should screen young adults for performance-enhancing drug use when unexplained cardiometabolic or endocrine abnormalities occur. Non-judgmental counselling and structured referral pathways for endocrinology and mental health are essential. Preventive strategies include education in gyms and universities and electronic medical record prompts for risk screening. These interventions are achievable within standard consultation timeframes and transferable across primary care settings.

Discussion: AAS use is associated with dyslipidemia, hepatic injury, hypertension, hypogonadism, and mood disturbance, conditions commonly first detected in primary care. Detection relies on confidential enquiry and targeted investigations. Ethical considerations include patient confidentiality, stigma, and balancing harm reduction with anti-doping principles.

Conclusion: AAS misuse among amateur athletes is a growing challenge for primary care. Early

detection, empathetic counselling, and coordinated follow-up reduce harm and support recovery.

ID 1994 - Coaching of interprofessional team practices to integrate physician assistants in XXX primary care within the project "Physician Assistants meet Allgemeinmedizin" (PAAM)

Dingzuan ZHANG, Yin Hang CHAN, Man Li CHAN, Pak Lik LI, Yeung Shing NG

Family Medicine And Public Health Care, Tuen Mun Hospital, Hong Kong, Hong-Kong

Context: Clinical encounters with patients presenting with mood problems in primary care settings have been increasing and the waiting times for psychiatrist consultation in the public sector are often long in XXX. To address this service gap, Integrated Mental Health Programme (IMHP) was introduced in the Family Medicine Clinics, which provides early assessment and timely treatment for those patients with mood disorders in the community.

Objectives: To evaluate service utilisation and patient clinical outcomes delivered within IMHP under primary care settings.

Methods: Cases managed under IMHP in the XXX Cluster of XXX from March 2022 to March 2025 were reviewed. Patients aged 18 years or above who attended Family Medicine Clinics for mood disorders, mainly depression or anxiety, were referred to IMHP. Patients were triaged to either key worker services alone or a combination of key worker and doctor services, stratified according to their PHQ-9 and GAD-7 scores. Counselling and treatment were provided at IMHP clinics by a multidisciplinary team. Patient outcomes were subsequently analysed.

Results: During the review period, 2,897 patients received IMHP services. Among these, 1,582 patients required integrated key worker and doctor services, with an average of 4.97 key worker consultations and 3.14 doctor consultations for each patient during that period. Following treatment, 77.4% of patients demonstrated clinical improvement with more than 50% reduction in PHQ-9 or GAD-7 scores. During the study period, 28.5% of patients were successfully discharged directly from the IMHP. In addition, 7.5% of patients were stepped down to Family Medicine Clinics after achieving a stable condition on anti-depressions, only 10.0% of patients were required to be referred to psychiatric specialist care.

Discussion: The IMHP demonstrated favourable clinical outcomes and multidisciplinary collaboration facilitated timely intervention for patients. The low rate of referral to specialist care demonstrate its effectiveness in gatekeeper role.

Conclusion: The IMHP provided an accessible and effective mental health service within the primary care settings for patients with mood disorders. It provided an efficient clinical pathway to reduce specialist referrals while ensuring timely and appropriate mental health care provision for patients in need.

ID 100 - The appropriate frequency of blood pressure screening in adults: a systematic literature review

Maria Alyssa DULATRE, Girlie RELLERA

Southern Isabela Medical Center, Santiago City, Philippines

Context: Terminal illness is never experienced in isolation. In family medicine, disease unfolds within relationships, shared responsibilities, and collective grief. Pancreatic cancer, often diagnosed late and associated with significant suffering, forces families to confront not only medical decisions but emotional, spiritual, and relational challenges. This case reflects on a family's shared journey through terminal illness and the role of family-centered hospice care in preserving dignity and connection.

Methods: This practice-based reflection describes a 70-year-old woman with metastatic pancreatic cancer referred for hospice care after disease-directed treatment was no longer appropriate. Care focused on symptom relief, home-based hospice visits, family counseling, and anticipatory guidance. Family medicine tools—including family functioning assessments, illness trajectory mapping, caregiver strain evaluation, and spiritual assessment—were used to understand the broader impact of illness. Changes in caregiver burden were monitored before and after hospice and counseling interventions.

Originality: Rather than centering solely on the patient's decline, this case places the family at the heart of care. It illustrates how structured family assessment and intentional counseling transformed caregiving from an isolating burden into a shared

responsibility, highlighting the relational work of the family physician during end-of-life care.

Lessons learned and future implications: The primary caregiver initially experienced severe emotional and physical strain. Through hospice involvement, open family dialogue, and redistribution of caregiving roles, caregiver burden was meaningfully reduced. Early recognition of caregiver distress and proactive family engagement can prevent burnout and foster resilience. Hospice care is most effective when introduced as a supportive presence rather than a last resort.

Discussion: As the patient's condition progressed, pain, dependency, and anticipatory grief reshaped family roles and exposed long-standing vulnerabilities. Hospice care reframed the experience of dying—shifting focus from fear and exhaustion to comfort, presence, and shared meaning. The family physician acted not only as a clinician but as a steady companion, helping the family navigate uncertainty, loss, and eventual bereavement.

Conclusion: This case affirms that compassionate, family-centered hospice care allows healing even when cure is no longer possible. By attending to suffering, relationships, and meaning, family physicians can help families endure loss with dignity, connection, and grace.

ID 417 - Biopsychosocial Determinants Profiling to Support Personalized Hypertension Care in XXX

Maria Beatriz MORGADO [(1)] , Rita LOPES DA SILVA [(2)], Anabela SCHINCK [(3)], Ana Patrícia MARTINS [(3)], Ana Cristina FERREIRA [(3)], Joana S. S. OLIVEIRA [(4)]

(1) Saúde Laranjeiro Family Health Unit, Almada-Seixal Local Health Unit; University Department Of Family Medicine, Lisbon School Of Medicine, Lisbon University, Almada, Portugal
(2) São João Do Pragal Family Health Unit, Almada-Seixal Local Health Unit, Almada, Portugal
(3) Costa Do Mar Family Health Unit, Almada-Seixal Local Health Unit, Almada, Portugal
(4) Costa Do Mar Family Health Unit, Almada-Seixal Local Health Unit; University Department Of Family Medicine, Lisbon School Of Medicine, Lisbon University, Almada, Portugal

Context: Portugal reorganized its health system in 2024 integrating hospitals and Primary Care (PC) into Local Health Units (LHU). This promoted research support infrastructures in PC, leveraging hospital-based research centers. Within this context, a team of PC professionals took the initiative to create a Practice-Based Research Network (PBRN): Research2Care.

Methods: PBRNs are collaborative networks of PC professionals, academics, and other healthcare providers aimed to produce relevant research to clinical practice. In Almada-Seixal LHU, six professionals initiated a network granted by the Clinical Research and Biomedical Innovation Agency and the Portuguese Association of General and Family Medicine. Research2Care was developed using a practice-based reflection approach. Despite major structural barriers, particularly the absence of protected research time in clinical schedules, the network grew over the past year to include 15 link-professionals (doctors and nurses) across health centers and partnerships with 8 entities (including 2 medical schools and 2 patient associations). It currently supports 13 projects—11 initiated by investigators—and collaborates with the hospital on joint applications for industry-sponsored clinical trials.

Originality: Although PBRNs are well-established internationally, the concept remains new in Portugal. Research2Care is a bottom-up initiative, adapting dynamically to local needs, especially bridging primary care and hospital research ecosystems, for which there was no previous history in PC research in this region.

Lessons learned and future implications: Research in PC is challenging without dedicated support structures. Research2Care provides free, integrated technical-scientific assistance within the health system, truly "win-win" collaborations. It manages research projects matching motivated professionals and facilitates LHU participation in national and international projects, promoting a true research culture.

Discussion: In a rapidly changing world, research must address patient and professional needs, starting in PC—the health system's entry point. Breaking barriers to create a culture of scientific excellence is essential. Research2Care aims to provide sustainable support for professionals conducting research in PC.

Conclusion: Establishing a PBRN reduces researchers' isolation and strengthens collaboration with secondary care, academia, and private institutions—enhancing evidence-based and person-centered practice, improving population health, and increasing system efficiency. This model is transferable to other health systems undergoing

integration, offering a scalable strategy to embed research within routine PC practice.

ID 683 - Improving the primary prevention of atherosclerotic CVD in patients with COPD in the primary care setting

Daniel SUAREZ, Rubén CABRERA, Javier URIOS, Irene URIOS, Daniel ESTAÑ, Ramon MUNERA, Mari Carmen PONCE, Alberto COLL, Sidi Mohamed BUJTEIH, Leticia MOLERON

Hospital De Orihuela, Orihuela, Espagne

Context: Diabetes mellitus (DM) is a chronic disease with a high morbidity and mortality rate, affecting 537 million people in 2030. Spain has the second highest prevalence of diabetes in Europe, at 14.8%, exceeding the continental average. Diabetic retinopathy (DR) is one of the many complications of diabetes.

Objectives: The goal is to enable primary care to assess the severity of diabetic retinopathy using portable retinal imaging devices. Developing referral algorithms to specialist ophthalmologists will facilitate more efficient referral of diabetic patients who have developed diabetic retinopathy.

Methods: Artificial intelligence (AI) software, trained using a deep neural network, has been developed to support diagnosis through the automated analysis and detection of diabetic retinopathy in retinal images obtained from a public repository of retinal photographs.

Results: A series of models (RETFound, ResNet-50, ResNet-152, DenseNet-121, DenseNet-169, and VGG-19) were used to analyze their performance in classifying different levels of diabetic retinopathy (DR). The RETFound model was used as a reference due to its strong performance. ResNet-50 and DenseNet-169 were the models with the best results for DR classification. ResNet-50 showed the best overall metrics, followed by DenseNet-169, both outperforming RETFound in most metrics except accuracy and training time. However, while metrics such as AUPRC and F1-Score are competitive, they are not high enough for fully independent diagnosis.

Discussion: The proposed AI-powered diagnostic support system (DSS) for diabetic retinopathy (DR) detection demonstrates acceptable performance, with an accuracy exceeding 97%, surpassing the results reported by other software in the literature in some metrics. The model enables primary care centers to perform initial triage and prioritize patients requiring specialized care, facilitating resource management and improving the efficiency and sustainability of the healthcare system.

Conclusion: For the healthcare system to survive, more efficient management of patients and resources is essential. Primary care physicians treat the diabetic population, and with the help of a referral algorithm using the portable retinal cameras available to them in primary care, they could assist ophthalmology services overwhelmed by the prevalence of this condition.

ID 746 - Age-Related Discrepancies in Hypertension Management: Insights from a Rural UK Primary Care Practice

Charlotte GOOLAERTS [(1)] , Clémence MUSY [(2)], Morgann PREY [(2)]

(1) Aix-Marseille University, Villeneuve-Lez-Avignon, France
(2) Aix-Marseille University, Marseille, France

Context: Climate change is considered by the WHO to be the greatest threat to human health. In 2019, WONCA called on general practitioners to commit to planetary health. Although they are aware of these issues, many struggle to translate them into concrete actions.

Objectives: Exploring barriers and enablers to general practitioners' involvement in raising patient awareness of climate change.

Methods: A qualitative study in accordance with the COREQ criteria and inspired by grounded theory was conducted among GP. Participants were recruited through theoretical snowball sampling until data saturation was reached. Fourteen semi-structured interviews were carried out and independently analyzed by two researchers, with data triangulation at each stage.

Results: Fourteen semi-structured interviews were conducted. Analysis identified several key themes. GP demonstrated unanimous awareness of climate change and its health impacts, and expressed a clear willingness to adapt their professional practices to contribute to mitigation and adaptation efforts. They emphasized their central role in prevention and health education, and agreed on the relevance of integrating environmental health into routine primary care. The co-benefits approach was

perceived as a pragmatic and acceptable strategy to address climate-related issues while respecting patients' individual vulnerabilities, lifestyles, and social contexts. However, they reported a perceived lack of legitimacy to address this topic, related to insufficient initial and continuing training, limited consultation time, fear of jeopardizing the doctor–patient relationship, and the absence of clear institutional guidance and practical tools.

Discussion: These findings are consistent with the literature and confirm the privileged position of GP in preventing climate change–related health effects. Participants expressed a tension between professional responsibility and perceived patient expectations during consultations. The co-benefits framework may help overcome this barrier by aligning environmental messages with immediate health benefits. Participants' concerns highlight the need for structured training, standardized recommendations, and institutional support to legitimize environmental health counseling. Exploring patients' expectations and acceptability through qualitative research could further inform implementation strategies in primary care.

Conclusion: GP are largely aware of the health effects of climate change. Embedding their role in environmental health promotion within broader societal awareness and strengthening institutional commitment would help legitimize this approach and facilitate its implementation in daily clinical practice.

ID 934 - Giant cell arteritis in primary care: a case report

Alicja WOS

Sleights And Sandsend Medical Practice, Scarborough, Royaume-Uni

Context: Chronic pain affects 30-50% of the adult UK population. Despite NICE guidelines recommending against their use for chronic primary pain, sciatica and back pain gabapentinoids are frequently overprescribed, leading to significant patient burden, NHS costs, and environmental impact. This study, set in a North Yorkshire GP-teaching practice, introduced a holistic, patient-centred consultation model to promote self-management and reduce gabapentinoid dependency.

Methods: Patients with repeated gabapentinoid prescriptions (excluding cancer, neuropathic, and palliative care) were identified via SystmOne. Following manual screening, 45 eligible patients were invited via Accurx; 14 participated. Each received a 45-minute, dedicated consultation with a GP registrar. This "safe space" facilitated a medication review and the co-creation of individualized lifestyle plans (diet, exercise, mindfulness). Outcomes were assessed via 2–6 week follow-up calls and a survey.

Originality: This project is innovative in its use of a single-practitioner, dedicated consultation time to integrate intensive, co-created lifestyle modifications within a framework inspired by Greener Practice projects base and resources.

Lessons learned and future implications: The study highlighted a high patient readiness for non-pharmacological dialogue when provided with a non-judgemental environment. Sharing the "pain story" was reported as inherently therapeutic. Future practice should consider protected consultation time or "Pain Cafes" (group consultations) to support sustained behavioural change. A key limitation was the small sample size and selection bias inherent in voluntary recruitment.

Discussion: Our findings mirror Declercq's (2021) observation of mind-body misalignment; a "safe space" allows patients to reconcile their "pain story" within a biopsychosocial framework. While Kristiansson (2011) highlights GP helplessness, our results suggest dedicated time mitigates this burden. Crucially, as evidenced in opioid titration studies (Goodman, 2018), clinicians can discuss reducing medication without damaging the therapeutic relationship, as many patients are already keen to taper when provided with a supportive, non-judgmental rationale.

Conclusion: A structured, holistic consultation can effectively pivot chronic pain management away from pharmacotherapy. This approach aligns with national de-prescribing goals, demonstrating that bespoke lifestyle interventions are a feasible and empowering alternative for patients burdened by medication side effects.

Context: As a life-threatening complication of bipolar disorder, suicide attempts represent a major point of medical contact in primary care and emergency settings.

Objectives: This study aimed to describe the clinical and circumstantial characteristics of these attempts, focusing on patterns relevant to initial assessment and management by first-line medical providers.

Methods: In this cross-sectional study, we analyzed data from 281 patients hospitalized for bipolar disorder over six years. We examined information on suicide attempts, including methods, location, timing, recurrence rates, and clinical severity. The cohort was stratified based on the presence or absence of a suicide attempt history for comparative analysis.

Results: A history of suicide attempt was identified in 22.8% of patients, with 71.4% of this group experiencing recurrent attempts. Medication overdose was the most common method (40.6%), primarily involving prescribed psychotropic drugs. Attempts most frequently occurred in the patient's home (76.6%), during evening hours (51.3%), and in the winter season (62.5%). A severe depressive episode was the clinical context in nearly 80% of attempts. While high suicidal intent was common (>80% of cases), only a minority of patients required subsequent intensive care unit admission.

Discussion: This profile suggests that suicide attempts in bipolar disorder often arise within recognizable clinical and environmental contexts, utilizing means readily available to the patient. Given that primary care physicians are frequently involved in post-attempt follow-up and pre-referral care, their role is pivotal. Enhanced awareness of these characteristic patterns at the primary care level is crucial for prompt recognition and urgent intervention.

Conclusion: Suicide attempts in bipolar disorder constitute a critical emergency that frequently presents initially to non-psychiatric medical services. Strengthening the capacity of primary care to recognize these emergencies and facilitate urgent referral is essential for improving patient outcomes and safety.

Corresponding author: Emna Hajji, hajji.emna@gmail.com

ID 2052 - Biomarkers and Progression of Cardiovascular-Kidney-Metabolic Syndrome: A Systematic Review and Meta-Analysis

Tiffany LE BLANC

Docteur, Larchamp, France

Context: Domestic violence towards women constitute a major Public Health concern. Its consequences on health are largely documented, especially on mental health issues, such as anxiety, depression, addictions or increasing risks of suicidal ideations. General practitioners have an essential role in preventing those situations, however it is still insufficient.

Objectives: Our study's goals are to identify and analyse the barriers that the Mayennais General Practitioners are experiencing when taking care of abused women.

Methods: We have done phone interviews with fifteen volunteers, to meet a qualitative approach.

Results: The results show multiple awaited barriers, such as the lack of time or when the patient is with someone else. Other obstacles regarding the therapeutic alliance and its ambivalence : an old connection, which initially seems to ease the communication, can actually to be a major blockage. But also, a fairly new connection can led to difficulties to open-up too. This ambivalence illustrates the complexity of the topic for the Practitioners. The fear of been too intrusive into patient's personal life is largely mentioned. In addition, not knowing about local associations seems to limit the possibilities to orientate and handover the patients to the appropriate service.

Discussion: This study enlighten the diversity of aspects that this topic covers. Talking about domestic violence force the Pratitioner to open-up to the patient's confession and welcome their stories. However, it is probable that some General Practitioners set they own limits for many reason, like the lake of education, screening tools or not

enough representation of domestic violence in the community. This block them to be freely able to screen women and prevent domestic violence.

Conclusion: Nevertheless, this study was particularly fulfilling, especially by the mobilisation of the Practitioners and they implication to open on different forms of violence. The study also allowed to enlighten the Mayennais network as well as the Pratitioner's role in this area.

ID 46 - Cardiovascular Outcomes Following Transition from Combustible Cigarettes to Heated or Electronic Tobacco Products Among Korean Adults with Type 2 Diabetes: A Nationwide Cohort Study

Felipe SANTOS, Caroline CORALES, Geissy SOUZA, Polyana CONCEIÇÃO, Fernanda DILLY

Icepi, Vila Velha, Brésil

Context: Pomeranians in Brazil primarily reside in rural areas, maintaining distinct cultural and religious customs. In the state of Espírito Santo, a significant population speaks the Pomeranian language, often facing high rates of illiteracy in Portuguese. These social determinants of health create substantial barriers to health literacy and treatment adherence within the Family Health Strategy.

Methods: This practice-based reflection describes interventions conducted by two physicians training in the rural communities of Tijuco Preto and Melgaço, Domingos Martins, between September 2021 and July 2022. Three main strategic activities were implemented: 1) Social Prescription : Visual prescriptions using hand-drawn illustrations, medication box cutouts, and stickers to overcome literacy barriers. 2) Culinary Recipe Booklet: Adaptation of traditional Pomeranian recipes to balance nutritional needs for patients with chronic diseases (hypertension, diabetes) without erasing cultural identity. 3) Linguistic Integration: Systematic use of Pomeranian keywords (e.g., greetings, symptoms, and medication colors) during consultations to foster trust and patient autonomy.

Originality: The approach shifts from a traditional biomedical model to a biopsychosocial one, utilizing low-cost, high-impact "soft technologies". By incorporating the Pomeranian language and visual aids into the clinical encounter, the project treats the consultation as a "social pact" rather than a unidirectional command.

Lessons learned and future implications: The interventions significantly improved patient satisfaction and treatment adherence. Valuing the patient's mother tongue transformed the doctor-patient relationship, encouraging active participation in decision-making. These strategies demonstrate that primary care equity can be achieved even in low-infrastructure settings by addressing linguistic and cultural specificities.

Discussion: The implementation of the "Social Prescription" addressed the reality of patients who, unable to read or identify medications, had their self-care compromised. This tool facilitated health literacy, defined as the ability to find and use information for health decisions. Furthermore, using the Pomeranian language changed the clinical dynamic: the dialogue, previously restricted to the physician and a translator, opened space for the patient's active participation. These actions align with the National Humanization Policy, which encourages shared management of care and the appreciation of the subjects' singularities.

Conclusion: Addressing health literacy through culturally sensitive tools is essential for effective primary care. This model is transferable to other ethnically diverse or low-literacy contexts globally.

Context: The strategic use of technology has significant potential to strengthen continuity of care and reduce health inequalities in primary care. Key areas include remote consulting, wearable devices, and, increasingly, point-of-care ultrasonography (POCUS). Remote consultations can bridge geographical gaps and improve timely access, while wearable devices enable remote monitoring of physiological parameters relevant to chronic disease management. POCUS represents a major upgrade of the traditional clinical examination, allowing clinicians to visualise most major organs directly during the consultation (the clinical ultrasound examination). Telemedicine platforms also enable remote supervision, second opinions, and integrated triage pathways. As these digital and imaging technologies become more common, often driven by access and resource constraints, sharing good practices, challenges, and implementation strategies across Europe is essential.

Objectives: • Learn about fast-moving research on e-health, including remote consulting, wearable devices, and POCUS with AI support. • Share experiences of opportunities and barriers in applying new technologies in primary healthcare across Europe. • Explore which SMART technologies most effectively enhance primary care delivery.

Teaching method and workshop: Presentations will summarize the latest research on remote consultations, wearable devices, and POCUS (including AI-supported applications, with emphasis on patient safety, feasibility, and acceptability. Most of the workshop will involve small group disc.

Expected outcomes: • Describe emerging technologies in primary care, including remote consulting, wearable devices, and POCUS, AI-assisted imaging • Evaluate the benefits and limitations of these tools in improving access, diagnostic accuracy, and continui.

Conclusion: Technology-driven solutions, including POCUS, AI-supported diagnostics, remote consulting and wearables offer compelling opportunities to overcome access barriers and strengthen primary care delivery, especially in rural and underserved communities. By combining evidence with practical experience, this workshop will help clinicians critically assess and adopt SMART innovations that enhance patient outcomes.

ID 781 - TyG Index vs HOMA-IR for Predicting Type 2 Diabetes in Young and Middle-Aged Adults: A Large Cohort Study

Mustafa YAVUZ, Beyzanur YAVUZ

Ankara Bilkent City Hospital, Ankara, Türkiye

Context: The global increase in life expectancy has resulted in a growing geriatric population, accompanied by higher rates of chronic diseases, polypharmacy, and fall-related morbidity. Domestic falls frequently result in traumatic injuries and secondary complications related to immobilisation. In family medicine practice, early identification of complications and comprehensive follow-up are essential to reduce morbidity and improve outcomes.

Methods: This case report presents a retrospective evaluation of a 92-year-old male patient who experienced multiple complications following a domestic fall. The clinical data were obtained with informed consent through hospital records, laboratory findings, radiological imaging, and discharge summaries. The clinical course was analysed chronologically, and complications and management strategies were discussed in relevant literature. The patient attended the emergency department after a nocturnal fall at home, which occurred when he tripped over a bathroom rug during nocturnal bathroom use due to benign prostatic hyperplasia (BPH). His medical history included BPH, chronic obstructive pulmonary disease, and atherosclerotic cardiovascular disease. Imaging revealed fractures of the proximal left humerus and left pubis. He was discharged with bed rest recommendations and a Velpeau bandage for shoulder immobilisation. Seven days later, the patient was readmitted with fever and deterioration in general condition. Investigations revealed elevated acute-phase reactants and radiological findings consistent with pneumonia. He was hospitalised and treated with intravenous antibiotics and thromboprophylaxis. During hospitalisation, immobilisation-related constipation and ecchymosis were identified and managed. The patient was discharged after clinical stabilisation.

Originality: The case is distinctive in presenting multiple immobilisation-related complications

within a single clinical course following a domestic fall in advanced age.

Lessons learned and future implications: Fall prevention strategies, early mobilisation, home safety modifications (e.g. removal of loose rugs, installation of grab bars, adequate lighting, non-slip bathroom surfaces, accessible emergency call systems, and caregiver awareness programmes), and multidisciplinary follow-up are crucial in geriatric patients.

Discussion: This case demonstrates that domestic falls in geriatric patients may trigger a cascade of complications beyond orthopaedic trauma. Immobilisation-related pneumonia and gastrointestinal dysfunction are common but frequently underestimated in geriatric care.

Conclusion: Comprehensive assessment and holistic follow-up after geriatric falls are essential. Family physicians play a key role in preventing secondary complications and enhancing patient outcomes through continuity of care.

Context: Healthcare professions are particularly susceptible to suffering from burnout. The prevalence of this pathology is higher than in the general population.

Objectives: To determine the prevalence of professional burnout among family doctors from 2016 to 2025.

Methods: This is a multicenter cross-sectional descriptive study composed of a network of volunteer sentinel doctors from 35 primary care centers, who distributed burnout questionnaires among their coworkers during the studied period. The Maslach Burnout Inventory adapted for healthcare professionals (MBI-HSS) was used to measure burnout. We defined burnout when scores in the three subscales simultaneously exceeded the following scores: Emotional Exhaustion (EE) equal to or greater than 27 points, Depersonalization (DP) ≥10 points, and Personal Accomplishment (PA) ≤ 33 points.

Results: With a staff of approximately 390 doctors. In November 2016, out of 82 surveys, 6% experienced burnout. In May 2019, with 119 responses, 11% presented burnout. In November 2020, with 84 participants, burnout cases reached 58.3%. In May 2021, with 160 surveys, burnout did not drop below 28%. In May 2022, with 123 responses, burnout reached 19.5%.In May 2023, 82 doctors responded to the survey, and burnout was 8.5%. In May 2024, out of 147, 32 met burnout criteria (21.7%). In May 2025, out of 83 responses, 12.3% suffered from it. The response rate ranged between 21% and 43%.

Discussion: The data from 2017, with 6% burnout, was similar to other previous Catalan publications. After the burnout chords from the end of 2018, during any 2019, burnout stabilizes at around 10%. But the arrival of the pandemic, burnout to exceed 50% of respondents.

Conclusion: Burnout among family doctors in the centers increased until reaching its historical maximum in 2020, 6 months after the outbreak of the pandemic. Subsequently, a progressive decrease began, with a spike in 2024 and a new decrease in 2025. It seems unattainable to return to the values of a decade ago.

ID 1491 - Association between Average Weekly Work Hours and Glycated Hemoglobin in Patients with Diabetes Mellitus: Korea National Health and Nutrition Examination Survey Results

Manar ALGHAMDI

Tabuk University, Tabuk, Arabie Saoudite

Context: In recent years, primary healthcare systems have undergone rapid digital transformation, including the expansion of telemedicine, electronic health records, and mobile health applications. These developments aim to enhance access, efficiency, and continuity of care. However, concerns remain regarding their implications for equity, patient liberty, and

humanistic values—core principles of General Practice and Family Medicine.

Objectives: To synthesize existing evidence on the impact of digital primary care interventions on equity, access to care, patient autonomy, and the humanistic dimensions of clinician–patient relationships.

Methods: A narrative literature review was conducted using PubMed, Scopus, and additional peer-reviewed databases. Publications from 2015 to 2025 were included. Search terms combined concepts related to primary care, digital health, telemedicine, equity, and patient-centered care. Inclusion criteria encompassed empirical studies, systematic reviews, qualitative research, and relevant policy analyses addressing digital primary care. Hospital-only studies and purely technical evaluations without patient or clinician perspectives were excluded. Data were thematically synthesized using an equity- and humanism-oriented analytical framework.

Results: The reviewed literature highlights a dual impact of digital primary care. Digital consultations and remote monitoring improved access for populations facing geographical, mobility, or time-related barriers and supported continuity of care for people living with chronic conditions. Conversely, persistent inequities were reported among older adults, individuals with limited digital literacy, socially disadvantaged groups, and those facing language or communication barriers. Several studies identified challenges in maintaining empathic communication, relational continuity, and shared decision-making in digitally mediated encounters.

Discussion: Digital primary care is neither inherently equitable nor inequitable. Its impact depends on social context, organizational models, and implementation strategies. When digital tools prioritize efficiency over relationships, humanistic care may be compromised. The literature emphasizes the importance of inclusive design, clinician training, and alignment with social determinants of health.

Conclusion: Digital primary care offers opportunities to improve access and system responsiveness, but may also risk widening disparities if equity and humanism are not explicitly addressed. Future research and policy should focus on patient-centered digital strategies that preserve relational care and promote equitable outcomes across diverse populations.

ID 1909 - Development of an algorithm for the discrimination of diabetic retinopathy in Primary care.

Katie BROWN, Aliki TRAIANOU

University Of Glasgow, Glasgow, Royaume-Uni

Context: Sustainability in healthcare is increasingly recognised as a vital competency for future medical professionals. The General Medical Council (GMC) guidance underscores the importance of understanding the broader determinants of health, including environmental impacts, to deliver high-quality, sustainable care. Climate change, resource depletion, and environmental degradation are directly linked to the global burden of disease, making it imperative to integrate sustainability principles into medical curricula. This module was developed to address this gap by equipping students with the knowledge, skills, values, and confidence to tackle complex health challenges within sustainable frameworks.

Methods: The teaching module on Sustainable General Practice employs a multi-method approach, including case-based discussions, interactive workshops, reflective activities, and problem-solving exercises. Content focuses on sustainable systems within the NHS, the environmental impact of healthcare practices, and strategies to enhance sustainability across patient care pathways. Real-world patient journeys are used to contextualise sustainability within clinical decision-making and system-level thinking. Interdisciplinary collaboration with colleagues in Secondary Care, Public Health, and Pharmacy further enriches perspectives on sustainable primary healthcare delivery.

Originality: This module introduces an innovative, flexible structure that adapts to diverse educational settings and learner needs. By integrating sustainability into authentic clinical contexts and fostering interdisciplinary engagement, it moves beyond traditional didactic teaching. The approach combines practical application with reflective learning, ensuring students develop both theoretical understanding and actionable skills for sustainable practice.

Lessons learned and future implications: Undergraduate implementation demonstrated increased awareness of sustainable healthcare principles, improved confidence in problem-solving,

and a positive shift in attitudes toward environmentally responsible practice. Feedback highlighted the module's authenticity and adaptability, suggesting strong potential for replication in postgraduate education. Future directions include scaling the module across curricula and exploring its impact on long-term professional behaviours and healthcare system resilience.

Discussion: Embedding sustainability within medical education is essential to prepare future doctors as proactive stewards of health in an environmentally conscious healthcare landscape.

Conclusion: This module represents a significant step toward achieving that goal, offering a replicable and adaptable model that aligns with global health priorities.

Context: Unwanted loneliness is widely recognized as a significant social determinant of health in the geriatric population, linked to poorer mental and physical outcomes. However, the specific influence of gender on the subjective experience of loneliness and its intensity among community-dwelling older adults warrants further investigation in primary care settings.

Objectives: To analyze the prevalence of perceived loneliness in older adults and to evaluate the existence of significant differences based on sex.

Methods: A descriptive, cross-sectional study was conducted in seven primary care centers. Participants were older adults (>65 years). Variables analyzed included sociodemographic data (age, sex, civil status, living arrangements) and subjective perception of loneliness (frequency, intensity, and feelings over the last 5 years). Statistical analysis was performed using the Chi-square test to assess associations between sex and loneliness indicators, considering $p<0.05$ as significant.

Results: A total of 1,303 individuals were included (57.0% women, 43.0% men), with a mean age of 70.4 years. A significant disparity in civil status was observed: 17.6% of women were widowed compared to only 3.4% of men ($p<0.001$). Regarding loneliness, 69.8% of men reported "never" feeling alone, whereas this percentage dropped to 56.9% in women ($p<0.001$). Conversely, women were twice as likely to report feeling alone "often" or "sometimes" (26.9% vs. 13.9%). Intensity of loneliness was also significantly higher in women ($p<0.001$). Furthermore, when asked about the last 5 years, 20.3% of women reported moments of loneliness compared to 11.5% of men.

Discussion: The results reveal a stark gender gap. Women not only report a higher prevalence of loneliness but also experience it with greater intensity. This is likely influenced by the higher rate of widowhood among women in this age group. The data suggests that while men may maintain social support structures longer (often through marriage), women face a "survival penalty" manifesting as increased isolation.

Conclusion: There is a clear gender inequality in the experience of loneliness among the elderly. Primary care strategies to address isolation should not be gender-neutral; they must recognize the specific vulnerability of older women, particularly those who are widowed, to design more effective community interventions.

ID 864 - Evidence-Based Approaches to Adult Constipation in Primary Care

Sky Wei Chee KOH

National University Polyclinics, National University Health System, Singapore, Singapore, Singapour

Context: Neonatal jaundice is common , but XXX current bilirubin-based follow-up (rather than guideline-recommended risk-stratified monitoring) may drive unnecessary visits, especially in a multi-ethnic context with higher XXX risk and breastfeeding-related persistence.

Objectives: To evaluate the factors affecting neonatal jaundice monitoring in primary care,

specifically in normal-risk newborns, with the aim of optimizing jaundice follow-up care through a risk-stratified approach.

Methods: We conducted a cross-sectional review of electronic medical records for newborns ≤90 days seen for neonatal jaundice across seven XXX (September 2022–August 2023), extracting anonymized demographics, birth weight, risk category, feeding, visit details, weights, hospital follow-ups, and TcB/SB results; unrelated visits were excluded and data were quality-checked. We performed descriptive statistics and bivariate comparisons (t-test, Mann–Whitney U, Chi-Square), and used negative binomial regression to identify factors associated with number of follow-up visits, reporting IRRs with 95% CIs; 62 records with missing birth weight were excluded from multivariable analyses. We also simulated a guideline-informed risk-based approach (XXX) versus the current bilirubin-based model to estimate safely avoided visits among normal-risk infants >7 days with bilirubin below age-specific phototherapy thresholds, applying local discharge criteria.

Results: 5,391 newborns attended 26,494 jaundice visits between 2022-2023, with 4,593 (85.2%) determined to be normal risk for severe hyperbilirubinemia. Compared to high risk newborns, normal risk newborns had significantly fewer visits (5 visits, IQR 2-7 vs 5 visits, IQR 4-7), higher birth weight (3.13kg, SD 0.47 vs 2.94kg, SD 0.43), lesser newborns reaching phototherapy thresholds (8.4% vs 27.9%), and lower jaundice discharge rate (71.4% vs 75.6%). Chinese (compared to Malay) (IRR 1.15, 95%CI 1.11-1.19) and male (IRR 1.10, 95%CI 1.07-1.13) newborns had higher follow-up rates, while higher birth weight (IRR 0.752, 95% CI 0.728 – 0.778) and normal risk (compared to high risk) (IRR 0.93, 95% CI 0.90 – 0.97) were associated with lower follow-up rates. Among normal-risk newborns >7 days old, none exceeded phototherapy thresholds.

Discussion: A simulated risk-stratified model could safely eliminate 3,652 visits (16.6%) among normal-risk infants, supporting pragmatic protocol refinements.

Conclusion: Our study provides insights into factors influencing jaundice follow-up visit rates. Further study is needed to implement and evaluate its effectiveness.

Context: Despite an abundance of studies focusing on work schedules and health, few have addressed the impact of duration or pattern of work on HbA1c levels in diabetic patients.

Objectives: We examined the relationship between average weekly work hours and glycated hemoglobin (HbA1c) levels in workers with diabetes.

Methods: Data of 1,556 workers with diabetes mellitus (DM) from the Korea National Health and Nutrition Examination Survey spanning 2007–2016 were analyzed. Multiple regression analysis (SAS v9.4) was used to assess the correlation between average weekly work hours and HbA1c level.

Results: Using 40–52 hours per week as the reference range, workers who worked more than 52 hours per week had significantly higher HbA1c levels (β: 0.2514; P=0.0087). This association remained significant (β: 0.2286; P=0.0308) among those working >52 hours in daytime shifts compared to than among those working standard 40–52 hour schedules. However, the correlation was not observed among other subgroup members who performed evening, night, regular, and irregular shifts.

Discussion: Workers with DM who worked long hours were prone to significant increases in HbA1c levels.

Conclusion: To mitigate this risk, workplaces should adhere to legal work-hour limitations and offer part-time options for employees with diabetes. Additionally, health education programs may help workers with diabetes manage their condition more effectively.

Context: General Practice/Family Medicine (GP/FM) is a fully accredited medical specialty requiring 3–6 years of postgraduate training across the EU. Yet, GP/FM remains listed in Annex 5.1.3 of the Professional Qualifications Directive at the EU legislation, meaning it is still not recognised as a specialty at EU level. This work aims to explain why this gap persists, outline the ongoing coordinated policy advocacy, and describe what EU-level recognition could bring in terms of training quality, safety, and care equity.

Objectives: This workshop aims to explain why this gap persists, outline the ongoing coordinated policy advocacy, and describe what EU-level recognition could bring in terms of training quality, safety, and care equity.

Teaching method and workshop: Descriptive analysis of the EU legislative framework, Member States' notifications, and the coordinated advocacy efforts led by European family medicine organisations. Evidence supporting the benefits of specialist-trained family doctors was drawn from pu

Expected outcomes: Participants will gain a clear understanding of the current EU barriers, the coordinated role of institutions, and practical advocacy tools. They will leave with a shared roadmap for national and European action, strengthened collaboration channels.

Conclusion: EU recognition of General Practice/Family Medicine is still pending, but progress is happening thanks to the joint efforts of Member States and European organisations. Working together remains essential to achieve the legislative change needed.

ID 131 - Association between small vessel disease and persons with overweight and obesity: A study using peak width of skeletonized mean diffusivity

Agne MESKAUSKIENE, Carl DEANEY

Marsh Medical Practice, Louth, Royaume-Uni

Context: Heart failure (HF) is a leading global cause of morbidity and mortality, disproportionately affecting older adults. WHO and WONCA emphasise equitable, person-centred chronic disease management, while NHS England (NHSE) prioritises improved access, shared decision-making and reducing unwarranted variation. Understanding patient-reported experience is essential to shaping community-based HF services and informing targeted quality improvement.

Objectives: To quantitatively evaluate patient experience of heart failure care in a rural English primary care setting, focusing on information provision, treatment tolerance, access, functional limitations and emotional impact.

Methods: A patient-reported experience questionnaire was electronically distributed, achieving a 100% consent rate. Descriptive quantitative analysis was undertaken, reporting proportions only. Free-text comments were reviewed to contextualise findings but were not thematically analysed due to sample size and the study's quantitative focus.

Results: Half of respondents were aged 61–70 years and 50% were ≥71 years; 75% were male. Diagnosis occurred within the past year for 38%, while 25% had lived with HF for over five years. Daily

life became “a bit harder” for 63%, with household tasks (63%) and walking or light exercise (50%) most affected. Information provision was partly adequate: while 25% felt information was “definitely” clear, 75% reported it was only “somewhat” clear. Most patients sought supplementary information online (75%) or from primary care HF teams (50%). Emotional and psychological burden was considerable: 88% worried about quality of life, 75% about family impact and the future, and 57% reported negative effects on mental health. Medicines were generally well tolerated, with 43% reporting no issues and 57% managing most medicines without problems. Symptomatic improvement was reported by 71%, mainly within 3–6 months (80%). Access was generally good: 71% found appointments “quite easy”. However, 57% didn't know who to contact if difficulties arose. All preferred face-to-face reviews. Functional limitations persisted, notably tiredness or breathlessness (57%).

Discussion: Findings indicate high symptom burden, partial gaps in information and coordination, and ongoing emotional impact. Results support NHSE and WHO priorities for enhanced self-management support, improved communication, and strengthened rural access systems.

Conclusion: This quantitative evaluation highlights clear opportunities to improve person-centred HF care through enhanced information, structured reviews and clearer access pathways, consistent with WONCA principles.

ID 535 - Effect of Major Weight Loss on Cardiovascular Risk in Severe Obesity: A Case Report

Míriam GARCÍA CERRAJERO, Angel Luis RODRIGUEZ SANTISTEBAN, Laura GARCÍA I SÁNCHEZ-OSORIO, Bepsi Keit QUISPE UNOCC, Maria COMPANYS MESEGUER, Wilsandra SENA MENDEZ, Paula BANASINSKA

Cap Turó Can Mates, Sant Cugat Del Vallès, Espagne

Context: SGLT2 inhibitors (SGLT2i) are the cornerstone of nephroprotection in current guidelines (KDIGO 2024), indicated for patients with Chronic Kidney Disease (CKD) and albuminuria to delay progression. However, their translation into real-world primary care practice may be lagging.

Methods: To evaluate the prescription rate of SGLT2 inhibitors in a cohort of primary care patients who objectively meet the criteria for CKD (low Glomerular Filtration Rate [GFR] and/or albuminuria). We use a cross-sectional study of 988 patients assigned to a family physician. We identified patients meeting KDIGO analytical criteria for CKD (GFR < 60 ml/min/1.73m² or ACR ≥ 30 mg/g). We then analyzed their active medication list to determine the prevalence of SGLT2i prescription (dapagliflozin, empagliflozin) within this specific target group.

Originality: Until now, we've conducted routine consultations without proper analysis of our medical procedures. This case has brought to light the reality of our patients' data. As a results a total of 69 patients met the objective criteria for renal damage. Among this high-risk group, only 14 patients (20.3%) were being treated with an SGLT2 inhibitor. The remaining 79.7% of patients with confirmed renal alteration were not receiving this specific nephroprotective therapy, suggesting a high degree of therapeutic inertia or a delay in adapting treatments to new evidence-based guidelines.

Lessons learned and future implications: From now on, we plan to assess the most appropriate treatment for patients with kidney damage in our daily practice to optimize their management.

Discussion: Despite robust evidence supporting SGLT2i for halting CKD progression, our data shows a penetration of only 20% in clear candidates. This gap highlights the difficulty of shifting prescribing habits in primary care and underscores the need for automated alerts or specific programs to identify candidates for treatment optimization.

Conclusion: There is significant underutilization of SGLT2 inhibitors in patients with objective markers of renal disease. Bridging this gap between guidelines and practice is an urgent priority to improve long-term renal prognosis.

ID 2060 - Sustainability in Obesity Management: A Critical Review of Weight Regain Following the Discontinuation of GLP-1 Receptor Agonists

Ana Beatriz MEIRA MAGALHÃES

Usf Paredes De Coura, Ponte De Lima, Portugal

Context: Alzheimer’s disease and related dementias (ADRD) affect over 60 million people

worldwide, resulting in significant emotional burden on informal caregivers. Existing mobile health (mHealth) applications largely fail due to non-personalized content (83% focus on generic education), lack of scientific validation (only 20% reviewed by specialists), and insufficient practical support.

Methods: This project proposes an integrated, user-centric mHealth application. The system will follow an evidence-based model, offering stage-adapted (mild, moderate, advanced) cognitive stimulation and psychosocial support. Personalization employs Explainable Artificial Intelligence (XAI) via SHAP algorithms to justify content recommendations , adapting to the user profile. Validation is secured through partnerships with neurologists and psychologists. Expected Outcomes include a 25% reduction in caregiver stress (based on Zou et al., 2024) and a 15–20% increase in patient cognitive performance. Strengths: validated information and dynamic personalization (vs. 6% of apps using AI). Limitation: reliance on external partnerships for updates.

Originality: The innovation lies in simultaneously resolving the three primary mHealth failures: non-personalization (via XAI and stage adaptation), lack of scientific validation, and excessive theoretical focus (via practical tools and external referencing to resources like Alzheimer Portugal).

Lessons learned and future implications: Key lessons emphasize the necessity of scientific validation and XAI transparency for user trust and adherence. Future challenges involve overcoming high post-launch abandonment rates (common in 71% of apps) and integration with the National Health System (SNS) for effective referral.

Discussion: The project is feasible due to reduced development costs (using open-source platforms) and strategic partnerships (e.g., university hospitals). This model encourages a shift towards validated, stage-adapted digital support in primary care settings, offering a superior alternative to generic applications.

Conclusion: This project provides a robust, evidence-based digital solution with strong potential to mitigate caregiver burden and improve patient cognitive outcomes. The next steps involve prototyping and executing clinical trials to measure real-world impact.

(3) Nextgenu.org, Toronto, Canada
(4) World Lifestyle Medicine Organization, Shomron Districts, Israël
(5) World Lifestyle Medicine Organization, Genevo, Suisse

Context: Chronic and lifestyle-related diseases continue to rise globally, yet most health professionals receive limited training in Preventive and Lifestyle medicine. Would-be preventionists, particularly in low-resourced settings, face significant challenges: limited instructor capacity, high curriculum development or purchase costs, and a lack of harmonized competencies aligned with global accreditation frameworks.

Objectives: Describe the structure of a competency-based Preventive & Lifestyle Medicine curriculum and its alignment with international standards. Identify strategies for locally adapting a modular curriculum using open-access educational resources. Map personal, trainee, and/or institutional training needs to core competencies and thematic areas in preventive and lifestyle medicine. Draft an initial hybrid training model within their own educational/clinical settings. Evaluate key components required for accreditation alignment, mentorship, and community-based practicum integration.

Teaching method and workshop: The workshop is designed to be a practical and collaborative learning experience, equipping educators with both the skills and the open-access tools (specifically from NextGenU.org) needed for effective curriculum development.

Expected outcomes: A draft curriculum suited to their personal or institutional learning desires. Knowledge of freely available modules that align with their learning desires. A preliminary implementation plan supporting your and your colleagues' intellectual and practical.

Conclusion: This workshop demonstrates how open-access learning and community-based practicums can equitably build global workforce capacity in preventive medicine through a scalable, locally adaptable framework.

ID 347 - Stiff Arteries, Stiff Joints: Exploring the Vascular - Osteoarthritis Link

Angel Luis RODRIGUEZ SANTISTEBAN, Cerrajero GARCIA, Wilsandra SENA MENDEZ, Francisco Javier MUÑOZ EXPOSITO, Paula BANASINSKA, Maria COMPANYS MESEGUER, Bepsi QUISPE UNOCC, Laura GARCIA I SANCHEZ-OSORIO

Cap Turó De Can Mates, Sant Cugat Del Vallès, Espagne

Context: Albuminuria is an early and sensitive marker of renal damage and cardiovascular risk, playing a central role in the 2024 KDIGO guidelines. Despite this, systematic screening of the Albumin/Creatinine Ratio (ACR) remains suboptimal in primary care, potentially leading to an underestimation of the real burden of early-stage Chronic Kidney Disease (CKD).

Objectives: To estimate the prevalence of significant albuminuria (ACR ≥ 30 mg/g) in primary care patients without a prior recorded diagnosis of CKD, and to classify its severity according to KDIGO 2024 prognostic categories.

Methods: An observational, descriptive, cross-sectional study was conducted in a single urban primary health care center. The sample included 988 adult patients from a single physician's quota who had recent analytical determinations. Laboratory data were cross-referenced with electronic health records to exclude patients with a pre-existing CKD code. "Occult albuminuria" was defined as a confirmed ACR ≥ 30 mg/g in undiagnosed patients, stratified into categories A2 (moderately increased: 30–300 mg/g) and A3 (severely increased: >300 mg/g).

Results: Out of the 988 patients analyzed, 25 subjects (2.5%) were identified with significant albuminuria despite having no prior clinical diagnosis of renal disease in their records. Detailed analysis of this "occult CKD" group revealed that 96% (n=24) were in stage A2 (microalbuminuria), while 4% (n=1) presented with stage A3 (macroalbuminuria). These patients were largely managing their health without specific renal monitoring or risk-adjusted nephroprotective treatment.

Discussion: Our findings confirm a relevant diagnostic gap in primary care. Approximately 2.5% of the general consulting population has analytical evidence of renal damage that goes unnoticed due to a lack of coding or systematic screening. The predominance of stage A2 suggests that the ideal window of opportunity for intervention—before irreversible damage occurs—is being missed.

Conclusion: Systematic implementation of ACR screening in routine practice identifies a significant percentage of patients with undiagnosed early renal damage. Detecting this "silent albuminuria" is crucial to initiating early nephroprotection measures and meeting KDIGO 2024 quality standards.

ID 704 - The Challenge of Fragility Fracture: A Clinical Case Report

Lucie DELOYE

Chu Besançon, Besancon, France

Context: Therapeutic advances have significantly improved outcomes for people living with HIV (PLWH), whose life expectancy is now close to that of the general population. As this cohort ages, clinicians increasingly face complex medical and social issues such as comorbidities, polypharmacy, frailty, reduced autonomy, and persistent stigma. With traditional infectious-disease–centered follow-up reaching its limits, reconsidering a more comprehensive care pathway becomes essential to support both health and ageing in this emerging population.

Objectives: - Discribe and understand who are the senior PLWH followed up at the Besançon University Hospital - Redifine the roles of general practicionner and specialists in a global and more inclusive care-pathway.

Methods: This observational, descriptive, cross-sectional study included 107 PLWH aged ≥65 years. Clinical and social data were extracted from electronic medical records and complemented by a questionnaire completed by 43 participants. Comorbidities and frailty were assessed using the Charlson Comorbidity Index and the Clinical Frailty Scale (CFS). Participants were categorized into three groups according to HIV infection duration (<15 years, 15–30 years, >30 years).

Results: The cohort was predominantly male, with a mean age of 72 years and a median HIV duration

of 25 years. Overall frailty was moderate (mean CFS 2.3), but comorbidities were common, particularly cardiovascular and renal. Interestingly, participants more recently diagnosed appeared more frail, possibly reflecting delayed diagnosis and limited integration into long-term care. In contrast, long-term survivors displayed more iatrogenic sequelae (lipodystrophy, neurocognitive issues) but generally showed better clinical stability.

Discussion: The study highlights the key role of general practitioners, who are recognized as central and trusted figures in patient support. Findings suggest the need for reinforced coordination between primary care and specialist HIV services. While infectious disease specialists remain essential, their role could evolve toward a "sentinel" function, with general practitioners taking the lead in managing multimorbidity. Geriatric expertise would be mobilized for the most complex situations.

Conclusion: Ageing among PLWH—an outcome of decades of effective care—now requires redesigned care pathways and anticipatory strategies centered on greater involvement of general practitioners. Preparing this transition is crucial to address the needs of future ageing cohorts, which will include more women and increasingly diverse populations.

(3) Cs Autol, Autol, Espagne

Context: Population ageing increases the number of frail older adults with advanced illnesses where hospital care offers limited benefit. Primary Care is often the only service able to provide continuous, person-centred end-of-life care. This case describes a home-based palliative approach for a 94-year-old woman with probable glioblastoma, highlighting symptom control, family support, and palliative sedation.

Methods: The patient had maintained full independence until she developed rapid functional decline and recurrent seizures over several months. Neuroimaging revealed an extensive brain lesion compatible with glioblastoma. Due to extreme frailty and limited expected benefit, a symptom-oriented approach was agreed upon. After hospital discharge, she remained at home with her husband, supported by her daughter. Primary care was contacted for worsening condition (GCS 6, inability to eat, refractory seizures, and distressing agitation). The family reported exhaustion and wished to avoid further hospital transfers. A comprehensive home assessment identified a last-days-of-life situation with refractory symptoms. The primary care team implemented rapid medication adjustments, continuous monitoring, and emotional support. Due to persistent seizures and agitation, proportional palliative sedation was initiated with family agreement, using continuous subcutaneous midazolam, morphine for dyspnoea and hyoscine butylbromide for secretions. Caregivers received guidance on signs of comfort and maintaining a peaceful environment. The patient remained comfortable and died peacefully at home 36 hours later.

Originality: Home-based palliative sedation is feasible but inconsistently implemented. This case highlights a primary-care-led model applied to a very old patient who had been fully independent before acute neurological decline and addresses sedation for refractory seizures, an area underrepresented in the literature.

Lessons learned and future implications: Early communication and shared decision-making prevent unnecessary hospitalisation. Primary care teams can safely manage home-based palliative sedation when goals of care are clear. Training in seizure management and rapid-response pathways may enhance equity in community palliative care.

Discussion: It illustrates the importance of proactive symptom management, family support, and interprofessional collaboration to ensure comfort for patients. The underrepresentation of sedation for refractory seizures in community palliative care literature highlights a need for further research.

Conclusion: Primary-care-led palliative sedation can ensure comfort, avoid futile interventions, and respect patient and family preferences, reinforcing the value of community-based end-of-life care.

Dokuz Eylul University, Faculty Of Medicine, Department Of Family medicine, Izmir

Context: Guillain–Barré Syndrome (GBS) may initially present with mild, nonspecific neurological symptoms. Early emergency department evaluations often appear normal, leading to missed diagnoses. In contrast, family physicians who know patients longitudinally can detect subtle deviations from baseline. This case illustrates how an unexpected administrative visit enabled early recognition of GBS in primary care.

Methods: A 47-year-old woman, routinely followed in her family health center, presented only to request an administrative document. Although she denied symptoms, her family physician observed abnormal gait and difficulty rising from a chair—changes not seen previously. Neuromuscular examination revealed symmetrical lower limb weakness and reduced patellar and Achilles reflexes. Reviewing the shared electronic record showed that she had visited the emergency department two days earlier for leg pain and fatigue, where routine tests were normal. Further questioning revealed difficulty climbing stairs the previous day and a recent gastroenteritis episode. With suspicion of early GBS, the physician arranged urgent neurology referral. Cerebrospinal fluid analysis demonstrated albuminocytologic dissociation, and electromyography confirmed acute demyelinating polyradiculoneuropathy. Early IVIG treatment resulted in progressive improvement.

Originality: The diagnosis was made not through symptomatic reporting but because the family physician recognized functional decline relative to baseline. This highlights how continuity in primary care provides diagnostic advantages over isolated emergency encounters.

Lessons learned and future implications: Continuity allows early recognition of subtle neurological abnormalities. Even non-medical visits can reveal serious conditions when clinicians assess function rather than rely solely on reported symptoms. Symmetrical weakness and diminished reflexes should prompt urgent neurological evaluation. Enhancing neuromuscular examination skills and strengthening referral pathways may reduce diagnostic delays.

Discussion: Early GBS is frequently missed in emergency settings due to nonspecific presentations. Primary care's longitudinal perspective enhances early identification, reducing risks such as respiratory failure and long-term disability.

Conclusion: Continuity, vigilance, and functional assessment in family medicine are essential for early recognition of rapidly progressive neuropathies such as GBS, thereby improving patient safety and outcomes. MeSH: Guillain-Barré Syndrome, Primary Health Care, Continuity of Patient Care, Neuromuscular Diseases, Early Diagnosis.

(3) Faculty Of Medicine Galati, Iasi, Roumanie

Context: Primary Sjögren's syndrome usually presents with chronic sicca symptoms, while acute sensory or ocular manifestations are atypical and may obscure the diagnostic pathway. When sudden sensorineural hearing loss (SSNHL) precedes other autoimmune features by several years, the connection is easily overlooked. This case illustrates the diagnostic complexity of recognizing Sjögren's syndrome in a patient with a long interval between an acute auditory event and subsequent ocular and cutaneous inflammatory manifestations.

Methods: A 58-year-old woman with no prior autoimmune diagnosis experienced abrupt unilateral hearing loss three years before the current evaluation. At that time, no systemic autoimmune disorder was suspected. Three years later, she presented with an acute episode of uveitis, a painful erythema-nodosum–like maculopapular eruption, Raynaud phenomenon, and newly developed mild ocular and oral dryness. A multidisciplinary workup included audiologic review, ophthalmologic assessment, immunologic testing, and evaluation of exocrine gland function. Laboratory investigations revealed anti-SSA/Ro antibodies and low complement levels, supporting active systemic autoimmunity. Salivary gland

evaluation and minor salivary gland biopsy confirmed focal lymphocytic sialadenitis, establishing the diagnosis of primary Sjögren's syndrome. Differential diagnoses—sarcoidosis, ANCA-associated vasculitis, systemic lupus erythematosus—were considered and excluded. Strengths of the evaluation included immune assessment and cross-specialty coordination. Limitations included the absence of biologic inflammatory syndrome and the difficulty finding a causal link with autoimmunity.

Originality: The long interval between sudden hearing loss and the emergence of ocular and cutaneous autoimmune manifestations is rarely documented in Sjögren's syndrome. While isolated reports describe auditory or ocular involvement, few detail a delayed multisystem trajectory suggesting evolving autoimmune dysregulation. This case differs by highlighting a "temporal dissociation" pattern that may obscure early recognition.

Lessons learned and future implications: Clinicians should maintain awareness that extraglandular autoimmune manifestations can precede classic sicca symptoms by years. Early consideration of autoimmunity in unexplained SSNHL could improve recognition of patients at risk . Multidisciplinary coordination are essential.

Discussion: This case highlights how atypical and temporally dissociated extraglandular manifestations—such as sudden hearing loss occurring years before uveitis, erythema nodosum, and Raynaud phenomenon—can precede the classic sicca features of Sjögren's syndrome.

Conclusion: Recognizing these uncommon systemic clues is essential, as early consideration of autoimmunity may facilitate timely diagnosis and prevent irreversible multisystem complications

ID 145 - Early Diagnosis of Sarcoidosis in Primary Care: A Case-Based Reflection from an Irish General Practice

Mary PRESTON, Mayra SANAULLAH, Ingrid WALLACE, Joanne SELWAY

Buckingham University, Buckingham, Royaume-Uni

Context: Primary care placements are central to undergraduate medical education, providing early exposure to community-based healthcare. These placements are expected to expose students to a representative patient population. However, little is known about whether the patients seen by students reflect practice demographics in terms of age and gender. Understanding these patterns is important for equitable and socially accountable learning.

Objectives: To determine whether the age and gender of patients seen by medical students during primary care placements reflect their host practice populations.

Methods: A cross-sectional study was conducted across five practices hosting third-year medical students during a Primary Care Block. Consultations involving students were identified via EMIS and SystemOne records. Patient age and gender were extracted and compared with practice-level demographic data from NHS Fingertips, an online public health platform providing population-level statistics on UK healthcare, including primary care patient demographics. Chi-square tests assessed differences in age and gender distributions between student-seen patients and the overall practice population.

Results: Four of five practices showed significant differences ($p<0.05$) in age distribution. Students saw proportionally more older adults and fewer children and adolescents than expected. Significant gender differences were observed in four practices ($p<0.05$), with students seeing a higher proportion of female patients compared to the practice population. When data were pooled across all practices, the average number of female patients seen was 23% higher than expected. Patterns were consistent across practices despite variation in overall demographics, such as age and gender makeup as well as deprivation levels.

Discussion: Reduced exposure to younger patients likely reflects current primary care pathways, where children and young adults increasingly access pharmacies, urgent care, or minor-illness services. Higher exposure to older adults aligns with increased consultation rates for multimorbidity. The overrepresentation of female patients mirrors national primary care trends.

Conclusion: Students' clinical exposure partly mirrors the demographic composition of their host practices. Awareness of these patterns can inform placement design and supervision to ensure equitable exposure to diverse patient populations. Future research should examine patient allocation processes and explore alignment with GP and registrar caseloads to optimise student learning experiences.

ID 381 - Evaluating the significance of the prevalence of chronic conditions on Healthier SG (HSG) uptake

Manon BRETAUDEAU

Dmg Sorbonne, Paris, France

Context: Death is a fundamental aspect of medical practice but remains a largely undertaught during medical education. General practice (GP) residents, who frequently serve on the front lines of patient care, are often exposed to deaths while still in the process of developing both their professional and emotional identities.

Objectives: Examine how GP residents in XXX experience the death of their patients on an emotional level, and to identify the coping strategies they employ in response.

Methods: A phenomenological qualitative approach was used among GP residents in XXX. Participants were recruited through resident groups and faculty newsletters. Eligibility criteria included completion of at least one internship as GP residents and prior involvement in end-of-life care. Semi-structured interviews were conducted between May and November 2022. Interviews were recorded, transcribed, and analyzed using NVivo software. Coding, categorization, and thematic synthesis adhered to COREQ-32 qualitative research standards. Data triangulation was conducted in collaboration with a sociology researcher to enhance analytical rigor.

Results: Nine GP residents participated. They described heterogeneous emotional reactions, including shock, helplessness, guilt, anger, and self-doubt. Emotional intensity depended on whether the death was expected, the relationship with the patient and family, and the level of team support. Coping strategies ranged from avoidance (emotional distancing, considering subspecialties with limited end-of-life exposure) to adaptive approaches such as seeking palliative-care training, discussing experiences with colleagues, reflective practice, or using emotion-focused strategies. Residents emphasized the lack of structured support.

Discussion: International literature shows that patient death is a major emotional challenge for medical trainees, often generating shock, guilt and uncertainty, especially when supervision is limited. The diversity of coping strategies reflects the absence of structured support. This study provides rich qualitative insight but is limited by a small sample and single geographical area. Patient death appears both destabilising and formative, exposing gaps in communication and emotional training. Findings highlight the need for structured debriefings, simulation training and reflective practices.

Conclusion: Patient death profoundly affects residents and influences both clinical practice and personal wellbeing. Reinforcing end-of-life education and implementing structured emotional support are essential to preparing future physicians for this inevitable dimension of care.

ID 826 - The Critical Role of Family Medicine Continuity in the Diagnosis of Guillain–Barré Syndrome

Jeong Uk BAI, Seo Eun HWANG

Seoul National University Hospital, Seoul, Corée (République de)

Context: Depression is a major public health problem that worsens chronic disease outcomes and burdens patients, families, and healthcare systems. Although air pollution is a potentially modifiable environmental factor, existing studies report mixed results and underrepresent XXX primary care populations. Clarifying whether long-term exposure relates to depression in these settings can guide screening, counseling, and collaboration with public health efforts.

Objectives: The purpose of this study was to investigate the association between air pollution and positive depression screening in XXX adults.

Methods: This cross sectional study included 17,763 (9329 men; 8434 women) adults who underwent health checkups. For each participant, one-year-lagged average concentrations of particulate matter with an aerodynamic diameter of 2.5 µm or less (PM2.5) and 10 µm or less (PM10), nitrogen dioxide (NO2), sulfur dioxide (SO2), and carbon monoxide (CO) were assigned using the Community Multiscale Air Quality model. Depressive symptoms were assessed using Patient Health Questionnaire-2 (PHQ-2). Logistic regression estimated odds ratios for positive PHQ-2 screening and linear regression estimated changes in continuous PHQ-2 scores per interquartile range (IQR) increase in pollutant levels.

Results: A positive PHQ-2 screen occurred in approximately 13%. In single-pollutant models, PM2.5 was not associated with positive screening (odds ratio 0.99, 95% confidence interval 0.95–1.04) after adjusting for age, sex, season, body mass index, smoking, alcohol use, physical activity, diabetes mellitus, hypertension, and dyslipidemia. Estimates for PM10, NO2, SO2, CO were similarly null. For the continuous score, the adjusted beta coefficient of PM2.5 was -0.013 (95% confidence interval -0.04–0.01) per IQR increase. Results of other pollutants were similarly near zero. Multi pollutant models did not show significant association. Sex and age stratified results were nonsignificant.

Discussion: The lack of significant association may reflect unmeasured confounding variables, limited exposure contrast, or reverse causation whereby depressive symptoms reduce outdoor time and actual pollutant exposure. PHQ-2, while practical for large scale screening, may underestimate symptom burden compared with the nine-item instrument.

Conclusion: The results of this study showed no clear association between exposure to air pollutants and depression by PHQ-2 screening. Longitudinal studies including finer exposure resolution, repeated assessments, and richer psychosocial and neighborhood data are warranted.

ID 1309 - Delayed Association of Sudden Hearing Loss and Uveitis in a Systemic Presentation of Sjögren's Syndrome

Yancho MADZHAROV, Georgi PETROV, Radost ASSENOVA, Gergana FOREVA, Daniela MILEVA, Zornitsa AMBAREVA, Gergana APOSTOLOVA, Georgi TSIGAROVSKI

Medical University Of Plovdiv, Dept Urology And General Practice, Plovdiv, Bulgarie

Context: Cardiovascular diseases (CVDs) remain the leading cause of mortality worldwide, placing prevention at the centre of primary care. Wearable devices such as smartwatches increasingly generate physiological and behavioural data that may complement traditional cardiovascular risk assessment and support personalised counselling. Their growing popularity raises questions about clinical usefulness, accuracy, workflow implications, and ethical considerations. Understanding how future GPs perceive such data is important for anticipating digital health integration into preventive care.

Objectives: To explore general practice trainees' perspectives on incorporating smartwatch-generated health information into a preventive consultation and its potential role in motivating cardiovascular risk reduction.

Methods: A qualitative descriptive study was conducted among postgraduate GP trainees at the Medical University of Plovdiv. A total of 51 participants completed a written, vignette- based questionnaire. The vignette described a 47-year-old man attending an annual preventive examination with a calculated SCORE risk who reported regular exercise and smartwatch use. Trainees were asked how they would integrate wearable-derived data into the consultation and how it might influence patient motivation. Responses were anonymous and open-ended. Thematic content analysis was applied, involving independent coding by two researchers, comparison of interpretations, categories, and development of overarching themes.

Results: Three thematic domains emerged. First, trainees perceived smartwatch data—such as step count, heart rate trends, and activity duration—as a useful supplement to conventional preventive assessments, enabling more personalised cardiovascular risk discussions. Second, most believed that visualising individual metrics could enhance patient motivation by increasing awareness, supporting goal-setting, and strengthening engagement in lifestyle change. Third, trainees identified potential limitations, including variability in device accuracy, risk of misinterpretation, unequal access, increased consultation time for data review, and unresolved ethical and legal concerns related to confidentiality, documentation, and medico-legal responsibility. The lack of structured protocols or guidance in primary care was frequently noted as a barrier to routine use.

Discussion: Future GPs recognise the potential value of smartwatch-generated data in cardiovascular prevention but emphasise the need for validated measurements, clear ethical and regulatory frameworks, and practical clinical workflows.

Conclusion: Addressing these requirements may support responsible and effective integration of wearable devices into general practice.

(2) Seoul Medical Center, Seoul, Corée (République de)

Context: Infertility management has traditionally focused on the female partner, often overlooking the male factor and the synergistic lifestyle habits of the couple. While physical activity (PA) is known to influence fertility, the impact of synchronous interventions targeting the couple as a unit remains under-synthesized.

Objectives: This review aims to evaluate the association between couple-based physical activity interventions and reproductive outcomes (natural conception, ART success rates, and semen parameters). It specifically assesses the efficacy of couple-based lifestyle modifications emphasizing progressive overload compared to individual-focused care.

Methods: We conducted a systematic review of randomized controlled trials (RCTs) and prospective cohort studies published between 2014 and 2025. The search strategy targeted studies involving both partners in subfertile couples. Key inclusion criteria were: (1) simultaneous assessment of PA in both partners, (2) use of objective measurements (e.g., wearables) or validated questionnaires, and (3) interventions including blended care or structured exercise programs (e.g., PEPCI, IDEAL studies).

Results: Synthesizing data from key studies (n=64 to 920 couples), results indicate that couples requiring ART engaged in significantly less vigorous PA compared to naturally conceiving couples. Notably, interventions emphasizing gradual progression from accessible activities (e.g., slow jogging, brisk walking) demonstrated high adherence across diverse body types and fitness levels. Blended programs (e.g., "Smarter Pregnancy") showed that when couples progressively increased intensity together, diet and exercise behaviors significantly improved. Evidence suggests that increasing PA from low to moderate-to-vigorous levels correlates with improved semen parameters and higher implantation rates.

Discussion: Findings consistently support a positive association between couple-level PA and reproductive outcomes. Crucially, high-intensity training is not a prerequisite; the progressive accumulation of exercise load—starting with low-barrier activities—mitigates fear of injury in sedentary individuals while maximizing physiological benefits. Shared aerobic activity creates a supportive environment for conception.

Conclusion: Couple-based PA interventions enhance natural conception and ART outcomes. The evidence supports clinical recommendations for universal, progressive exercise protocols—starting with simple movements like slow jogging and gradually increasing intensity. This offers a low-cost, equitable strategy to improve fertility outcomes for couples of all ages, body types, and fitness backgrounds.

Pau VILURBINA PÉREZ, Montserrat PINYOL MARTÍNEZ, Minerva MAS HEREDIA, Maria José GINER MARTOS, Adrián DIAZ CASTILLO, Cristina DONCEL VALCARCEL, Luis GONZÁLEZ DE PAZ, Jaume BENAVENT ÀREU, Antoni SISÓ-ALMIRALL

Capsbe, Barcelona, Espagne

Context: Point-of-care ultrasound (POCUS) in primary care is expanding as a tool to improve diagnostic capacity, reduce delays and avoid unnecessary referrals. However, real-world comparative data with hospital imaging pathways remain limited. This study analyzes the performance of ultrasounds performed in a primary care center versus those referred to hospital, focusing on diagnostic delay, need for second imaging tests, and cost impact.

Objectives: To compare primary care versus hospital-based ultrasound pathways in terms of (1) diagnostic delay, (2) frequency of second imaging requirements, and (3) direct cost differences, in order to assess the efficiency and clinical utility of a local POCUS program in family medicine.

Methods: A retrospective study was conducted at CAP Les Corts using 2024 activity data. All abdominal and reno-vesical/prostatic ultrasounds performed in the primary care center were

compared with those referred to hospital during the same period. Variables collected included time to test, frequency of second diagnostic imaging after the first ultrasound, and direct cost differences based on official local pricing.

Results: A total of 516 ultrasounds were performed at the primary care center versus 1,953 at the referral hospital. The mean delay to complete the test was significantly shorter in primary care (28.87 ± 14.76 days) compared with hospital pathways (52.69 ± 68.74 days) ($p<0.05$). After primary care ultrasound, 41 cases required a second imaging test (27 additional ultrasounds, 10 CTs, 4 MRIs). Despite these cases, the implementation of a primary-care-based ultrasound circuit resulted in an estimated direct cost saving of €27,224 in 2024. Local availability also improved accessibility but generated some demand pressure requiring scheduling optimization.

Discussion: Primary care ultrasound reduced waiting times and costs, with a relatively low rate of complementary imaging. POCUS can safely absorb demand traditionally routed to hospitals. Increased accessibility may drive additional requests, highlighting the need for structured agendas, clear referral criteria, and coordination with radiology to maintain appropriate use.

Conclusion: Primary care ultrasound reduces diagnostic delays and offers significant cost savings while maintaining an acceptable need for complementary imaging. These results support further expansion of POCUS in family medicine settings.

ID 1816 - SMART solutions for primary care to overcome access barriers: sharing experiences with e-health across Europe

Susana Andreia CORDEIRO RITA NEVES, Carlos Daniel BENTO

Usf Gago Coutinho, Lisboa, Portugal

Context: Blue sclerae in infants may represent a benign variant or signal underlying connective tissue disease. Family physicians are often the first to detect these findings and must differentiate constitucional causes from heritable disorders such as osteogenesis imperfecta (OI) or Ehlers-Danlos syndrome (EDS).

Methods: A 24-month-old boy presented at routine surveillance with persistent blue sclerae and mild motor delay requiring physiotherapy. Examination revealed generalized joint hypermobility. Family assessment identified similar hyperlaxity in the father, previously undiagnosed. Neither the child nor father had fractures, dentinogenesis imperfecta, chronic pain or easy bruising. The combination of blue sclerae and familial hypermobility raised suspicion for a connective tissue disorder.

Originality: Blue sclerae are a clinical sign, not a diagnosis. Joint hypermobility is a key diagnostic clue. When present in the child and in a parent, it strongly shifts the differential toward hereditary connective tissue disorders, particularly Ehlers–Danlos syndrome (EDS). Family assessment is essential in primary care. Examining parents for subtle features (hypermobility, skin signs, fracture history) often reveals patterns missed in isolated paediatric evaluation. Mild OI or hypermobile EDS may present only with blue sclerae and motor delay—absence of fractures does not rule them out. Primary care is crucial for timely recognition of hereditary connective tissue disorders and ensuring appropriate multidisciplinary follow-up.

Lessons learned and future implications: Need for clearer primary care algorithms for children with connective tissue “red flags” such as blue sclerae, hypermobility, hypotonia, and recurrent pain. Improved interdisciplinary collaboration between family medicine, paediatrics, ophthalmology, physiotherapy, and genetics for children with suspected collagen disorders. Potential for developing primary care educational modules on connective tissue disorders, given their under-recognition and wide phenotypic spectrum.

Discussion: This case highlights the diagnostic challenge of blue sclerae in infancy and the importance of recognising joint hypermobility as a key clue to EDS. Primary care physicians play a central role in early detection, family evaluation, and coordination of referral pathways. Identifying subtle connective tissue signs in relatives can guide earlier diagnosis and management.

Conclusion: Persistent blue sclerae with joint hypermobility should prompt a structured evaluation, including family assessment and genetic referral. Primary care is crucial for timely recognition of hereditary connective tissue disorders and ensuring appropriate multidisciplinary follow-up.

ID 162 - Too much water, too little salt: hyponatremia and seizure following colonoscopy preparation

Sujeong SHIN

Department Of Family Medicine, Kangbuk Samsung Hospital, Sungkyunkwan University School Of Medicine, Seoul, Corée (République de)

Context: Cardiovascular disease (CVD) is a leading cause of global mortality. While early management of risk factors is central to primary care, individual outcomes vary. Although genetic predisposition and lifestyle behaviors contribute to CVD risk, their combined influence on mortality remains understudied in large populations. Understanding this interaction is crucial for determining if lifestyle changes can offset inherited disease susceptibility.

Objectives: This study examined how family history of CVD and modifiable lifestyle factors jointly affect CVD mortality, aiming to determine if healthy behaviors can reduce familial risk in primary care.

Methods: We analyzed data from 780,647 adults who underwent health examinations between 2002 and 2022, excluding those with CVD or cancer history. Participants were grouped by family history (yes/no) and lifestyle behavior tertiles (Healthy: 3rd tertile; Unhealthy: 1st–2nd tertiles). The lifestyle score integrated smoking, obesity (BMI ≥25 kg/m²), physical activity, blood pressure, fasting glucose or HbA1c, and non-HDL cholesterol. Cox proportional hazards models estimated hazard ratios (HRs) for CVD mortality.

Results: During 7,675,706 person-years of follow-up, 1,404 CVD deaths occurred, with an incidence rate of 18.3 per 100,000 person-years. Compared with the reference group (Healthy Lifestyle/No Family History), the hazard ratio (HR) for CVD mortality was 1.05 (95% CI 0.58–1.88) for those with a healthy lifestyle and family history. The HRs were elevated in groups with an unhealthy lifestyle: 1.84 (1.47–2.31) for those without a family history and 2.06 (1.57–2.69) for those with a family history. Individuals with a family history who maintained a healthy lifestyle showed no significant increase in mortality risk compared with the reference group.

Discussion: Our findings align with the growing evidence that favorable lifestyle behaviors substantially mitigate cardiovascular risk, even among individuals with inherited susceptibility. In this study, an unhealthy lifestyle conferred a greater increase in mortality risk than did family history alone. These results emphasize that family history is not deterministic but rather serves as a marker to identify patients who may derive particular benefits from intensive lifestyle counseling.

Conclusion: Healthy lifestyle behaviors lower CVD mortality risk, neutralizing excess risk from family history of CVD. Strengthening lifestyle modification should be prioritized for primary prevention in family medicine.

ID 181 - Acute Alpha Chloralose Intoxication: A Descriptive Study in the emergency department

Celina Azureen MOHD JEFRI CHAND, Suriani SULAIMAN

Presint 9 Health Clinic, Putrajaya, Malaisie

Context: Cat bites to the hand are high-risk injuries, especially in diabetic patients, because narrow puncture wounds inoculate bacteria deeply into poorly vascularised structures such as tendon sheaths and joints (1,2). Early presentations may appear mild, leading to delays in diagnosis and treatment. This case, managed in a primary care setting, highlights the challenge of detecting deep infection early, the limitations of oral antibiotics, and the importance of imaging and timely escalation.

Methods: A 53-year-old woman with suboptimal type 2 diabetes sustained a cat bite to her left wrist complicated with mild cellulitis despite completion of oral amoxicillin–clavulanate. She returned with worsening swelling and persistent wrist pain- red flags for deep hand infection. Although blood tests and radiography were normal, ultrasound showed tendon-sheath fluid and features of suppurative tenosynovitis. Surgical exploration confirmed pus within a sloughy tendon sheath, and cultures were negative. She completed six weeks of antibiotics (intravenous and oral) and received hand rehabilitation and glycaemic optimisation.

Originality: This case highlights how early cat-bite injuries in diabetic patients can be difficult to diagnose, as initial signs may appear mild and routine tests may remain normal despite deep infection.

Lessons learned and future implications: Cat-bite wounds in diabetic patients require reassessment within 48–72 hours. Red flags should prompt imaging and early referral. Culture findings should not guide decisions when clinical suspicion is high.

Discussion: Diabetes increases susceptibility to deep infection due to impaired immunity and microvascular compromise. Cat bites penetrate tendon sheaths and joints, where antibiotics have poor penetration (1–3). Pain on passive stretch, progressive swelling, and fluctuance—indicate deep tissue involvement (3). Cat-bite wounds often seal quickly, masking deeper spread (2). Negative cultures are common—reported in up to 39% of cat-bite infections—because of fastidious organisms and prior antibiotic use (1,2,4). When antibiotics fail, surgical drainage is often needed (4). Ultrasound is valuable in guiding escalation (1,2).

Conclusion: Cat bites to the hand in diabetic patients may hide deep infection despite mild appearance. Failure to improve within 48–72 hours warrant prompt re-evaluation and imaging. Disability can be prevented by timely referral and treatment escalation.

ID 240 - Marburg Heart Score and INTERCHEST score for telephone triage of acute chest pain: a prospective, diagnostic accuracy study in out-of-hours primary care

Seung Hee KIM

Department Of Family Medicine, Wonkwang University School Of Medicine, Wonkwang University Sanbon Hospital, Gunpo, Corée (République de)

Context: Although the renal protective effects of statins are known, their effects on renal function show inconsistent results depending on the study participants and types or intensity of statins.

Objectives: We examined the change of renal function after long-term use of moderate-intensity atorvastatin and rosuvastatin in the primary care patients.

Methods: We enrolled 247 patients with dyslipidemia who started taking atorvastatin10-20mg or rosuvastatin 5-10mg and maintained each for more than one year. After 1:1 ratio propensity score matching of the two groups, 68 subjects were selected from each. The demographic characteristics, anthropometric parameters, lifestyle, comorbidities, renal function, and cardiometabolic parameters of both groups were analyzed. Changes in creatinine, estimated glomerular filtration rate (eGFR) and cardiometabolic parameters before and after statin administration in both groups were analyzed by paired t-test.

Results: When comparing renal function after long-term use of atorvastatin or rosuvastatin, there were no significant changes in creatinine (from 1.02±0.15, to 1.01±0.15 mg/dL, P-value=0.14) and eGFR (from 74.7±12.5, to 75.6±12.4 mL/min·1.73m2, P-value=0.87) in the atorvastatin group and creatinine (from 1.02±0.16, to 1.01±0.17 mg/dL, P-value=0.05) and eGFR (from 76.0±10.2, to 77.8±12.3 mL/min·1.73m2, P-value=0.99) in the rosuvastatin group. Additionally, significant reductions in total cholesterol, low-density lipoprotein cholesterol, triglycerides and blood pressure were observed in both groups.

Discussion: In this study, long-term use of moderate-intensity atorvastatin and rosuvastatin did not significantly affect renal function in patients with dyslipidemia without renal disease. In the future, a large-scale prospective study is needed to determine the effect of statin types and intensity on renal function in various patient groups.

Conclusion: Long-term use of moderate-intensity atorvastatin and rosuvastatin did not have a significant impact on renal function in adults with dyslipidemia who did not have kidney disease and improved cardiometabolic parameters.

ID 427 - Traumatic Brain Injury: A Systematic Review of Mechanisms, Epidemiology, Imaging Findings, and Emerging Biomarkers

Alexandre FERRO, Naila OLIVEIRA

São Leopoldo Mandic Araras, Araras, Brésil

Context: Anxiety crises are significant mental health issues globally, with a 3.6% worldwide prevalence in 2017 according to the WHO. In Brazil, the rate reaches 9.3%, higher than in many other countries. Early identification enables more comprehensive care, and structured simulation is a valuable tool for developing essential clinical skills.

Methods: The simulation was organized by the medical education league and conducted in a controlled environment at São Leopoldo Mandic College in Limeira. An actor portrayed a patient who, during a routine consultation, experienced an acute anxiety episode marked by sudden fear or intense discomfort, palpitations, shortness of breath, tremors, and fear of imminent death or loss of

control. Groups of four to six students participated in each session, tasked with identifying the crisis, practicing active listening and patient reception, and later discussing management strategies with supervising professors.

Originality: Primary Care is the entry point to the Unified Health System (UHS), and professionals must be prepared to address all demands presented at this level. Simulation supports training for comprehensive care and reinforces the role of Primary Care in early recognition and management of mental health conditions.

Lessons learned and future implications: Students showed adequate knowledge in identifying anxiety crises and improvement in anamnesis, active listening, and patient reception. The activity highlighted the relevance of simulation in preparing future professionals to care for patients with mental health issues. For future editions, including a multidisciplinary team and expanding discussions on referral pathways may further enhance learning.

Discussion: The simulation positively impacted students' readiness to interact with patients in anxiety crises. Debriefing and active involvement in case discussions were essential for consolidating knowledge and strengthening clinical reasoning in a safe environment.

Conclusion: The simulation proved valuable in preparing future health professionals for first-contact care of patients experiencing anxiety crises, improving identification skills and promoting comprehensive, patient-centered care. As a safe and realistic learning scenario, it encourages active engagement and offers educators new possibilities for teaching in clinical and controlled settings. Simulation remains an essential tool in training professionals who will work in Primary Care.

ID 1044 - Cat-Bite–Associated Tenosynovitis in a Diabetic Patient: A Case Emphasizing the Limits of Empirical Antibiotic Therapy

Shanella AFOY [(1)] , José SOLIS TZAQUITZAL [(2)], Presenna SUNTHARASARMA [(1)]

(1) Université De Versailles Saint-Quentin-En-Yvelines, Paris, France
(2) Université Sorbonne Paris Nord, Paris, France

Context: HIV infection has become a chronic condition with highly active antiretroviral therapy (HAART), requiring long-term follow-up shared between hospital specialists and general practitioners (GPs). Coordination between these settings is crucial to ensure continuity of care and maintain quality of life for people living with HIV (PLWH).

Objectives: To explore how PLWH in the Île-de-France region experience shared care between primary and hospital settings, and to identify perceived benefits, barriers, and expectations regarding this care model.

Methods: We conducted a qualitative study based on seven semi-structured interviews with PLWH receiving both hospital and community care in Île-de-France. Interviews were audio-recorded, transcribed verbatim, and analyzed using Interpretative Phenomenological Analysis (IPA). Data analysis involved investigator triangulation, with double coding by the lead researcher and a senior supervisor followed by consensus discussions. The study received approval from the university data protection officer and the CNGE national ethics committee.

Results: Receiving an HIV diagnosis emerged as a particularly challenging moment that shaped subsequent relationships with healthcare professionals. Shared care was generally perceived positively, combining hospital specialists' technical expertise with GPs' holistic, longitudinal approach. Participants emphasized the importance of trust, continuity, and clear communication between providers. However, several barriers were reported: variability in clinical practice, insufficient HIV-specific training for GPs, limited use of digital tools for information sharing, and persistent gaps in hospital–community communication, all of which can weaken the effectiveness of shared care.

Discussion: These findings are consistent with calls to strengthen the role of primary care in HIV follow-up while underscoring the organizational and symbolic barriers that still constrain shared care in everyday practice. Acceptance of shared care appears closely linked to patients' trust in their GP and to clearly defined, complementary roles between primary and hospital care.

Conclusion: PLWH are favorable toward shared care as long as GPs are adequately trained and communication with specialists is regular, structured, and efficient. This study highlights the need to enhance continuing education for GPs in

HIV care and to optimize digital coordination tools to support integrated, patient-centered follow-up.

ID 1455 - Strengthening Heart Failure Care in Rural Primary Care: Quantitative Insights from Patient-Reported Experience Aligned with WHO, NHSE and WONCA Priorities

Maher BEN HAMIDA [(1)] , Rebeh BOUGOSSA [(1)], Ahmed TRABELSI [(2)], Asma BEN MABROUK [(1)], Jihene CHELLI [(1)], Faouzi ABID [(2)], Fatma LARBI [(1)]

(1) Department Of Endocrinology, Internal Medicine And Infectious Diseases, University Hospital Of Mahdia, Mahdia, Tunisie
(2) Department Of Orthopedic Surgery, Taher Sfar University Hospital, Mahdia, Tunisie

Context: Tuberculosis remains a major public health problem in Tunisia, where extrapulmonary forms are frequent. Osteoarticular tuberculosis (OT) is uncommon, and carpal involvement is particularly rare and frequently misdiagnosed. We report a case of carpal tuberculosis in a 39-year-old immunocompetent man.

Methods: A 39-year-old man with no past medical history from a rural area in the Tunisian Sahel, presented with an 18-month history of progressive swelling and pain of the right hand and wrist, without fever, weight loss, or other general symptoms, and with no improvement despite multiple empiric antibiotics courses for presumed pyogenic infection and anti-inflammatory drugs in primary care. Clinical examination showed mild inflammation of the dorsal aspect of the right hand and wrist, with preserved but painful wrist mobility and no neurovascular deficit. Chest radiograph was normal, the right wrist radiograph revealed osteolytic lesions of the carpal bones, and the tuberculin skin test was positive. Bacteriological examinations of soft tissue and carpal bone biopsy specimens were negative, but histopathological analysis revealed epithelioid and multinucleated giant-cell granulomas with caseous necrosis. The patient received a 12-month course of anti-tubercular therapy combined with osteoarticular debridement and tenosynovectomy. The clinical course was marked by regression of the swelling and microbiological sterilization, but with persistent functional limitations of the wrist and hand.

Originality: This case illustrates an unusual osteoarticular localization of tuberculosis in an immunocompetent adult, presenting as isolated carpal involvement without pulmonary or other extrapulmonary localizations.

Lessons learned and future implications: This case underscores the need for primary care clinicians in tuberculosis-endemic settings to consider OT in any chronic monoarthritis or persistent wrist swelling, even without constitutional symptoms.

Discussion: Carpal tuberculosis is an uncommon form of OT. Its presentation is often insidious, with nonspecific signs that may mimic chronic inflammatory or pyogenic arthritis. As microbiological tests may be negative, imaging findings and histopathological examination are essential for diagnosis. Treatment, based on anti-tubercular therapy with or without surgical intervention, should not be delayed minimizing the risk of functional sequelae.

Conclusion: In tuberculosis-endemic countries, chronic wrist or hand swelling of unclear origin should systematically raise suspicion of OT. Early recognition and treatment are critical to prevent irreversible functional sequelae with this uncommon condition.

ID 2136 - “Everyone Has Morning Headache”: Carbon Monoxide Exposure Suspected from One Key Question

Katy CHISENGA-PHILLIPPS

University Hospitals Sussex, Brighton, Royaume-Uni

Context: Returning to clinical practice after maternity leave is a major professional transition for many doctors. Through informal professional conversations across multiple NHS specialties—including General Practice, hospital medicine and community-based roles—recurring challenges have emerged relating to confidence, workload, identity, and workplace culture. Understanding how these NHS-wide themes manifest uniquely in General Practice is increasingly important for workforce retention, wellbeing and training quality.

Methods: This reflection draws on iterative professional discussions with NHS mothers working in varied clinical environments. These conversations explored lived experiences of returning to clinical work, including emotional, organisational and practical challenges. Themes were identified through reflective comparison across contexts, with

a focus on how shared challenges diverge in General Practice due to continuity demands, intensity of workload, consultations requiring autonomous decision-making, and the structure of supervision. No formal research methods were used, and no identifiable information was collected.

Originality: The comparative, cross-specialty perspective presented here highlights universal themes while identifying elements that are particularly pronounced in General Practice—such as rapid re-assumption of independent clinical responsibility, limited protected orientation time, and the emotional weight of continuity with patients after extended absence. This GP-specific lens on an NHS-wide issue is seldom addressed within training pathways or workforce guidance.

Lessons learned and future implications: Across specialties, returning mothers commonly experience reduced confidence, emotional load, guilt, pressure to perform at pre-leave levels, and overlooked physical or psychological recovery needs. Within General Practice, these challenges are amplified by workload intensity, continuity expectations and variable supervisory structures. Supervision styles and managerial confidence in supporting returners varied widely, highlighting a significant training need. Informal peer support and phased returns were consistently valued. The findings suggest opportunities for clearer practice-level guidance, improved supervisor training, psychologically safe environments, structured return-to-work conversations, and formalised support pathways for parents returning to General Practice.

Discussion: Addressing these issues aligns with broader priorities in primary care relating to equity, humanism, and workforce wellbeing. Improving the return-to-work experience may support retention and strengthen early-career GP development.

Conclusion: A structured, compassionate and proactive approach to supporting returning mothers can enhance wellbeing, confidence and retention in General Practice.

(1) Family Medicine Resident, Madrid, Espagne
(2) Family Medicine Attending, Madrid, Espagne

Context: Primary healthcare with an urgent referral to the Emergency Department.

Methods: Woman, 74 years old, with a medical history of hypertension and dyslipidemia. She presents to a Primary Care facility with right-sided temporal pulsatile headache accompanied by scalp hyperalgesia, decreased visual acuity in the right eye and right temporal artery light tenderness that started 24 hours before. The headache does not improve with usual painkillers. Given the presence of headache red-flags, she is referred to the Emergency Department. In the Emergency Department, laboratory tests reveal an erythrocyte sedimentation rate of 31 mm/hr and a C-reactive protein level of 16 mg/dL. Given the suspicion of giant cell arteritis (GCA), she is started on methylprednisolone 500 mg for 3 days and admitted to the Rheumatology ward. Further evaluation with ultrasound shows a halo sign with positive compression maneuvers in the frontal branches of both temporal arteries. A temporal artery biopsy is taken with normal results. The patient's symptoms improve, she is discharged and continues with outpatient follow-up.

Originality: GCA usually presents with jaw claudication and constitucional symptoms, in our case, the patient didn't have any of this symptoms and only presented visual and scalp hyperalgesia.

Lessons learned and future implications: In a Primary Care setting, besides the importance of recognizing headache red-flags, the Southend GCA Probability Score should also be used when point of care C-reactive protein is available, as it has high sensitivity prediction.

Discussion: GCA is a systemic vasculitis that primarily affects medium and large arteries, especially the extracranial branches of the carotid artery. It typically affects adults over 50 and presents with temporal headache, scalp tenderness, jaw claudication, constitucional symptoms and visual disturbances. Elevated inflammatory markers are common. Prompt diagnosis and immediate corticosteroid therapy are essential to prevent irreversible vision loss, making it the principal reason of why this diagnosis should be in mind of every primary care provider facing a red-flag headache.

Conclusion: Even though, a patient doesn't present the usual symptoms of GCA, GCA should be suspected in the diferencial diagnosis of a headache with red-flags in Primary Care and the patient should be referred to the Emergency Department. Key words: Giant Cell Arteritis; Headache; Ultrasonography.

ID 1362 - Aging with HIV: Clinical, Functional and Care-Pathway Challenges in Primary Care – A Cross-Sectional Study of Adults Aged 65 and Older, followed at the University Hospital of Besançon, France

Taron SHAGOYAN

Health For Armenia, Vedi, Arménie

Context: This rural Health Center serves approximartely 4000 individuals. No structured screening of 12-15-year-olds had been conducted in the previous three years due to resource constraints. This project introduced systematic screening of BMI and vision in 12-15-year-olds.

Methods: The Center director, school nurse, and school administration developed an action plan that included the formation of registries, periodic screenings, and data entry. The majority of students were examined at the school. Students registered in the Center but attending schools outside the community were examined at the facility. Challenges included increased staff workload due to new procedures, limited resources, and difficulty accessing students enrolled in schools outside the community.

Originality: Preventive care and quality improvement are relatively new concepts in this country. Despite longstanding guidelines for screening of children and adolescents, systems to ensure completion were absent in this region, and compliance was poor. Against this backdrop, the Health Center and the school implemented a standardized local screening pathway to support early detection of growth and vision disorders. This is a first step to establishing a culture of early detection and preventive healthcare.

Lessons learned and future implications: Structured and coordinated work is required during collaboration between the healthcare and education sectors. Even under limited resources, it is possible to build effective mechanisms if clear responsibilities, good coordination, and strong communication exist between involved parties. Furthermore, accurate data collection and proper data management can ensure continuity. The standardized process, coordinated by the Health Center director, will ensure ongoing screening of two school classes per month, with findings recorded by the school nurse and entered into the health information system by the Health Center operator.

Discussion: Screening rates went from near zero in 2024 to 92% in 2025. Vision disorders were identified in 18 students, obesity in 24, and undernutrition in 9. Several children underwent repeat examinations, others remain under assessment, and some were referred to secondary care for specialist evaluation. Parent and teacher awareness of adolescent health risks has increased.

Conclusion: This initiative restored a culture of health monitoring and strengthened collaboration between the school and Health Center, clarifying the distribution of responsibilities for adolescent preventive care.

ID 1588 - Perceived loneliness in the elderly: is there a gender gap?

Nataša NASKOVSKA ILIEVSKA

None, Maribor, Slovénie

Context: Burnout is a major threat to primary care sustainability across Europe, and Slovenia faces similar challenges. Slovenian studies demonstrate consistently high burnout levels among family medicine trainees and practicing GPs. A national study of trainees reported high emotional exhaustion in 45.9%, high depersonalisation in 43.1%, and low personal accomplishment in 45.9% . Among 316 Slovenian family doctors, 6% scored high on all three MBI dimensions, with risk factors including rural workload, high patient volume, and chronic illness. Qualitative research further highlights work–family conflict—especially for female trainees.

Methods: A scoping review of Slovenian research on burnout (2008–2025) was conducted, including quantitative cross-sectional studies, qualitative interview studies, and meta-analytic occupational stress research. In addition, reflective semi-structured interviews were held with Slovenian GPs (n = 12) working in urban, semi-rural, and rural practices to identify practical coping strategies.

Findings were synthesised through thematic analysis across individual, interpersonal, and organisational domains.

Originality: This work is the first to integrate all major Slovenian burnout studies across primary care with new qualitative insights from frontline GPs. It uniquely situates international burnout concepts within the specific realities of Slovenian healthcare, including patient load patterns, rural service expectations, the structure of GP training, and cultural expectations surrounding work and family roles. The combined evidence allows for tailored, actionable recommendations for Slovenia rather than generic resilience strategies.

Lessons learned and future implications: Small, realistic organisational changes matter. Formalising peer support is not used enough. Micro-recovery strategies, training flexibility is essential to addressing burnout risk among family medicine traiinees and specilists.

Discussion: Three themes consistently emerged: 1. Structural and Workload Pressures Dominate High daily patient volume, administrative overload, and limited organisational flexibility—especially in rural practices—were key drivers identified in Slovenian studies and interviews. These factors reduce autonomy and amplify emotional exhaustion. 2. Work–Family Conflict Is a Distinctive Slovenian Burden 3. Empathy and Relationship-Centered Care: A Double-Edged Sword.

Conclusion: Slovenian evidence shows that burnout among GPs is shaped by a combination of heavy workload, empathy demands, and work–family conflict. Effective prevention requires strategies that focus on system-level redesign, structured collegial support, and practical micro-recovery, rather than relying on resilience alone.

ID 1704 - A Geriatric Fall at Home Complicated by Immobilization-Related Morbidities: A Case Report

Ana FAGGIOLI

Usf Águas Livres, Lisbon, Portugal

Context: Constipation is a frequent complaint in Primary Care and a significant cause of discomfort among adults. It may present as an acute or chronic condition and often results from a combination of physiological, behavioural, and lifestyle factors. For Family Medicine physicians, identifying common causes, recognizing alarm signs, and understanding therapeutic options is essential for effective management and prevention.

Objectives: This review aims to summarize recent updates in clinical guidelines on the management of constipation in adults and to highlight the central role of primary healthcare professionals in patient education, preventive counselling, and timely intervention.

Methods: Guidelines and evidence-based recommendations from the Cochrane Library, UpToDate, the World Gastroenterology Organization, and the American Gastroenterological Association were reviewed. The analysis focused on diagnostic approaches, first-line non-pharmacological measures, and the comparative effectiveness of available pharmacological and mechanical interventions.

Results: Effective management of constipation begins with careful clinical evaluation and early implementation of preventive strategies. General measures—including hydration, dietary fibre optimization, physical activity, and patient education—are consistently recommended as first-line therapy. When these are insufficient, pharmacological options may be considered. Evidence suggests that polyethylene glycol is more effective than lactulose, particularly in improving stool frequency and abdominal comfort. Mechanical interventions may be appropriate for selected cases, depending on symptom severity and underlying causes.

Discussion: Constipation is often underreported by patients, reinforcing the need for clinicians to proactively inquire during consultations. Primary Care physicians are uniquely positioned to reduce symptom burden through personalized management plans and to promote long-term behavioural changes that support bowel health. Awareness of updated guidelines enhances the capacity to deliver comprehensive and patient-centred care.

Conclusion: Constipation should not be overlooked in routine Primary Care practice. Early recognition and individualized treatment strategies improve patient outcomes and prevent unnecessary complications. Ongoing familiarity with current evidence and guideline recommendations is essential to ensure effective and tailored management for adult patients. Keywords: Constipation, Primary Health Care, Adult

ID 983 - Carpal tuberculosis: a case report

Inga AKHTIEVA

Health For Armenia, Nor Hachn, Arménie

Context: This polyclinic serves 13,000 individuals in a small city and nearby villages. Diabetes screening was not being performed according to current guidelines, due to lack of systematic approach and data system limitations. This project aimed to improve compliance with guidelines for diabetes screening among patients 35–68 years-old.

Methods: A family physician identified eligible patients through the electronic medical record. The physician and nurse designed and implemented a system to ensure screening was conducted when patients visited the polyclinic for other complaints; nurses made calls to patients who did not come in. Data was collected in Google Sheets and analyzed by the medical staff, who also performed the examinations and assessed risks. Encountered challenges included: population passivity, staff workload, and difficulties with data entry. Teamwork and administrative support facilitated progress.

Originality: WHO states that 537 million adults worldwide live with diabetes, and every second patient is unaware of their condition. In this country, a significant portion of patients are diagnosed only when complications arise; participation in preventive examinations is poor. Quality improvement is a new concept in most practices, as is team-based care. Through this project, it was possible to increase screening of the target population, as well as improve interest and engagement among the medical staff.

Lessons learned and future implications: Team collaboration and data digitization are essential for success of screening initiatives. Population engagement requires education and communication approaches. For sustainability of the program, all healthcare workers will continue to be involved, while administration will ensure oversight and accountability.

Discussion: Approximately 32% of the target population was successfully screened, compared to 5% in 2022 and 10% in 2023. Of these, eleven patients (4%) were diagnosed with diabetes, and 18 (7%) were prediabetic. Updated numbers for the full year of 2025 and comparison to the whole polyclinic will be included in the final poster.

Conclusion: This project proved that through collaboration between doctors and nurses, support from the administration, and use of appropriate data management systems, it is possible to implement successful community awareness activities to improve early detection of type 2 diabetes.

ID 1057 - Is Family History Destiny? The Mitigating Role of Healthy Lifestyle on Cardiovascular Mortality Risk

Anees ALYAFEI, Muna ALSAADI, Saad AL QURAISHI, Heba AL BEER, Zena AMINALLA, Anthony DE LIMA, Rawia YASIN

Primary Health Care Corporation, Doha, Qatar

Context: Knee Osteoarthritis (KOA) management requires long-term maintenance and multidisciplinary support to prevent functional decline. Evidence suggests that structured Physical Exercise (PE) can alleviate symptoms and enhance joint function when combined with standard management. Within primary health care, the XXX Center delivers a multidisciplinary program that combines gym and aquatic exercise to complement standard treatment. The objective was to evaluate the effectiveness of a PE program on knee disability among adults with KOA attending the XXX Center.

Methods: This quality-improvement project was implemented at the XXX Center between May 2022 and May 2024 using the Plan–Do–Study–Act model. Eligible participants were adults with clinically stable KOA who had completed standard management. Exclusion criteria included acute flare-ups, medical contraindications, or poor adherence. Participants were allocated to one of two groups: (A) Combined gym + swimming or (B) Swimming-only, where each had 2–3 sessions/week, 60 minutes each for 12 weeks. The Knee Injury and Osteoarthritis Outcome Score (KOOS), which assesses knee-related disability, was administered at baseline and 12 weeks. Scores range from 0 (severe problems) to 100 (no problems), with a target of ≥10% from baseline. A total of 115 adults participated, including 69 females (60%), with a mean age of 60.1 years. Seventy engaged in mixed exercise and 45 in aquatic-only sessions. Mixed-exercise participants showed greater KOOS improvements (pre = 60.1; post = 74.9, 81.9, 78.3 in 2022, 2023, and 2024), whereas aquatic-only participants demonstrated smaller or inconsistent gains.

Originality: This project introduces a primary–care–based model for KOA management through a structured PE. Unlike traditional management settings, it integrates gym and aquatic therapy within a primary care center, demonstrating functional improvement in real-world settings over 3 years.

Lessons learned and future implications: Lessons highlight the superior outcomes of combined PE modalities and the benefits of multidisciplinary support. Future directions include integrating PE after the standard management and conducting longer-term evaluations.

Discussion: The findings demonstrate that integrating a structured, multimodal PE within primary care can meaningfully improve KOA outcomes, reinforcing the value of lifestyle-medicine approaches in routine management.

Conclusion: Embedding structured PE programs within primary care is an effective and scalable strategy to improve KOA outcomes.

ID 1406 - Free, competency-based Preventive & Lifestyle Medicine learning resources for our and our planet's health

Isabel GARCÍA CHUECO [(1)] , Claudia JIMENEZ HERNÁNDEZ [(2)], Cinthya HERNÁNDEZ ZÚNIGA [(3)]

(1) 18/1812019, Motril, Espagne
(2) 18/1813337, Motril, Espagne
(3) 18/184506108, Motril, Espagne

Context: A 58-year-old woman with no relevant medical history presented to the clinic consulting with abdominal distension and pain for several months. Laboratory tests and an abdominal X-ray were performed with not abnormal findings. She is advised lifestyle modifications, including gluten and lactose restriction, however, did not improve. Patient later developed a low-grade fever, vomiting, and diarrhea, which led her to seek care at local hospital.

Methods: During hospital visit abdomen was distended, tympanic, muscular rigidity upon palpation on right iliac region. The rest of the abdomen was unremarkable. An abdominal X-ray was ordered, which again showed no findings. Blood tests revealed only a C-reactive protein (CRP) of 52.8 mg/L. Given blood work results and clinical finds, appendicitis was suspected which led to perform en abdominal ultrasound detecting free fluid en the intraperitoneal cavity. Further investigation was carried out with abdominal CT and angiography, leading to a diagnosis of peritoneal carcinomatosis.

Originality: The finding of free fluid in the intraperitoneal cavity allowed other diagnosis to be considered, therefore, requesting further and more detailed imaging study until finally coming to the final diagnosis of peritoneal carcinomatosis which was initially not considered.

Lessons learned and future implications: This case allows us to assess the importance of point-of-care ultrasound (POCUS) in primary and emergency care. Although ultrasound is not the imaging diagnostic technique of choice for peritoneal carcinomatosis, it could have revealed secondary findings earlier if bedside ultrasound had been done in clinic by trained professional, therefore being able to diagnose much earlier when symptoms started demonstrating what Moien A. B. Khan y Fikri M. Abu-Zidan said US could see a minimum of free fluid of up to 10 mL in peritoneal cavity if done correctly.

Discussion: Despite abdominal point-of-care ultrasound (POCUS) having it´ s weakness being a user-dependent method requiring extensive training, it is an economical and effective tool that, when included in clinical practice, can help physicians achieve early diagnostic guidance and more confident decision-making if ultrasound data is correlated with the clinical evaluation of patients.

Conclusion: We consider training primary care physicians in POCUS to be an investment in the future, especially in resource-limited or hard-to-reach areas.

ID 1664 - The Holistic Chronic Pain Consultation: Integrating Lifestyle Interventions to Enhance Self-Management in Primary Care

Meredith DONALDSON, Carl DEANEY

Marsh Medical Practice, Louth, Royaume-Uni

Context: Adequate blood pressure (BP) management is essential to reduce cardiovascular risk in patients with hypertension. Guidelines recommend individualised BP targets, particularly for older adults, to balance the benefits of control with the dangers of overtreatment. Despite these recommendations, real-world data suggest variation in achievement of target BP across age groups and care settings.1

Objectives: To evaluate age-related differences in hypertension management and potential overtreatment in a rural primary care practice, using national audit data from CVD PREVENT (June 2025).

Methods: Patients with GP-recorded hypertension and the assessed achievement of BP targets over the preceding 12 months were analysed. Cohorts were stratified by age (<80 years vs ≥80 years). Potential overtreatment was assessed by identifying patients prescribed at least one antihypertensive with low systolic BP followed by a subsequent antihypertensive prescription. Practice-level performance was compared with the local Primary Care Network (PCN) and national averages.

Results: Overall BP control: Our practice, 75.71%; PCN, 68.64%; national, 68.27%. Patients <80 years: Our practice, 74.06%; PCN, 65.73%; national, 65.3%. Patients ≥80 years: Our practice, 82.13%; PCN, 80.24%; national, 79.61%. Potential overtreatment: Our practice, 0.78%; PCN, 0.6%; national, 0.52%.

Discussion: These data indicate a higher achievement of BP targets in older patients (≥80 years) than in younger patients (<80 years). While overall overtreatment rates were low, slightly higher rates in our practice warrant monitoring.

Conclusion: Our findings reveal an age-related discrepancy in hypertension management, with younger patients less likely to achieve target BP than older adults, despite similar guideline recommendations. These results suggest opportunities to optimise BP control in younger patients while maintaining vigilance against overtreatment in older adults. Targeted interventions focusing on age-specific barriers may further improve cardiovascular outcomes in primary care.

ID 382 - Behavioral Health Training Priorities in Residency: Perspectives from Early-Career Physicians

Radost ASSENOVA, Snezhina KIRILOVA, Gergana FOREVA, Yancho MADZHAROV, Daniela MILEVA, Zornitsa AMBAREVA, Gergana APOSTOLOVA, Georgi PETROV, Georgi TSIGAROVSKI

Medical University Of Plovdiv, Dept Urology And General Practice, Plovdiv, Bulgarie

Context: Multidisciplinary teams (MDTs) are considered the standard of care in oncology, yet their structure and function vary widely across countries. In Bulgaria, MDTs often operate informally, and the extent to which GPs are recognised as meaningful contributors remains unclear. Given GPs' continuous, long-term relationships with patients and their role in addressing psychosocial determinants of health, understanding their perceived contribution within MDTs is essential for strengthening integrated cancer care.

Objectives: To explore how GP trainees perceive their role, contribution, and barriers to participation in informal MDTs caring for patients with prostate cancer.

Methods: This qualitative study was conducted during postgraduate training in General Practice. A vignette describing a typical informal MDT interaction for a patient with prostate cancer was presented to trainees. Participants (n = 50; 21 men, 29 women; mean age 29,2 years) provided written responses to the prompt: "What cultural and professional barriers are visible to you as a GP?" Inclusion criteria were current enrolment in postgraduate GP training and consent to participate. Data were analysed using thematic analysis to identify recurrent perceptions, barriers, and interpretive patterns.

Results: Four major themes emerged: Strict biomedical orientation: MDT discussions were perceived as focused exclusively on tumor markers, imaging, and treatment protocols, with psychosocial factors viewed as peripheral. Undervaluing the GP's role: GP input was often considered secondary to specialist perspectives, reflecting cultural norms that frame GPs as administrators rather than clinical partners. Low integration of psychosocial determinants: Patient fears, family pressures, financial constraints, and adherence challenges were rarely acknowledged despite their clinical relevance. Professional segmentation and weak communication: Specialists were described as working within narrow clinical boundaries, limiting receptiveness to holistic information provided by GPs.

Discussion: The findings suggest that current informal MDT structures provide limited space for the biopsychosocial expertise of GPs. This may reduce care coordination and weaken patient-centred cancer management.

Conclusion: Enhancing the integration of GPs into MDTs—through formalised structures, clearer role definition, and improved interprofessional communication—may strengthen continuity of care and better address psychosocial needs in prostate

cancer management. Further research should evaluate system-level mechanisms to support this integration. Keywords: Primary Health Care; Multidisciplinary Team; Prostate Cancer; General Practitioners; Qualitative Research.

ID 482 - The Training Path of the CFSMG Campania Region: Objectives and Teaching Methodologies

Sujeong SHIN

Department Of Family Medicine, Kangbuk Samsung Hospital, Sungkyunkwan University School Of Medicine, Seoul, Corée (République de)

Context: Early identification of individuals at high risk for type 2 diabetes is a priority in primary care, especially among young and middle-aged adults, where subtle metabolic changes often go unrecognized despite long-term consequences. The homeostatic model assessment of insulin resistance (HOMA-IR) is widely used but has limited practicality in routine care. The triglyceride–glucose (TyG) index has emerged as a simpler surrogate marker, yet it remains unclear whether changes in TyG outperform changes in HOMA-IR in predicting diabetes risk.

Objectives: This study compared the predictive performance of changes in the TyG index versus HOMA-IR for incident type 2 diabetes in young and middle-aged adults.

Methods: We conducted a cohort study of 281,012 adults aged 18–49 years with ≥2 routine health visits. Changes in the TyG index and HOMA-IR were categorized into quintiles based on within-person differences. Incident type 2 diabetes was defined as fasting glucose ≥126 mg/dL, HbA1c ≥6.5%, or initiation of antidiabetic medication after baseline. Sex-specific hazard ratios (HRs) were estimated using Cox proportional hazard models.

Results: During follow-up, 5,965 men (4.09%) and 1,737 women (1.28%) developed type 2 diabetes. Increases in the TyG index demonstrated a clear graded dose–response relationship with diabetes risk. Among men, HRs ranged from 0.65 (95% CI 0.59–0.71) in Q1 to 2.17 (2.00–2.36) in Q5; among women, from 0.53 (0.44–0.63) to 2.63 (2.24–3.08). HOMA-IR showed a similar pattern but with weaker gradients across quintiles.

Discussion: The results indicate that longitudinal changes in the TyG index better identify individuals at elevated risk for type 2 diabetes than changes in HOMA-IR, particularly in younger populations. The stronger gradient associated with TyG suggests that it captures early metabolic alterations linked to insulin resistance more sensitively than traditional measures. Because the TyG index is simple, inexpensive, and based on routine laboratory values, tracking its changes in primary care could enhance early detection and preventive strategies.

Conclusion: TyG index changes showed a stronger correlation with type 2 diabetes onset than HOMA-IR changes. These findings support the TyG index as a practical and accessible tool for improving diabetes risk stratification and guiding targeted interventions in primary care settings.

ID 774 - Family Medicine Residency e-Portfolio Competency Evaluation in Korea

Chung Wai NG

Singapore Health Services, Singapore, Singapour

Context: During a novel respiratory pandemic, primary care clinics form the first point of contact for patients and visitors. Clinics must rapidly triage individuals based on symptoms and exposure risk, identify potentially infected persons, and manage or refer them according to established protocols. At the same time, continuity of care for patients with non-infective acute and chronic conditions must be preserved. Achieving safe segregation of potentially infectious patients from others requires clinic infrastructure that supports pandemic workflow, yet infrastructure is difficult to modify once constructed. This reflection examines the planning considerations for clinic layout to ensure pandemic readiness.

Methods: We reviewed the design and workflow planning process for a new primary care clinic, focusing on pandemic triage requirements in the event of a novel respiratory pandemic. Key considerations included establishing a single triage point, segregated patient and staff movement according to risk zones, and dedicated waiting areas for each zone. Critical service points including laboratory, radiology, and pharmacy were evaluated for specialised infrastructure needs such as radiation shielding, and temperature and humidity controls. Separate ventilation systems were planned for high- and low-risk zones. Tabletop exercises were conducted to test whether infrastructure aligned with intended workflows, including scenarios involving medical emergencies and fire incidents

within different risk zones. Strengths included early infection prevention team involvement and close collaboration with facilities teams. Limitations included the challenge of anticipating all future outbreak scenarios.

Originality: Although pandemic preparedness literature often focuses on clinical protocols, fewer reports address the structural and workflow design of primary care clinics. This experience highlights a proactive, infrastructure-centred approach that integrates infection prevention principles into early planning.

Lessons learned and future implications: Pandemic-ready infrastructure requires early multidisciplinary collaboration and scenario testing. Workflow considerations must encompass routine care, outbreak triage, and emergency contingencies.

Discussion: Aligning infrastructure with clinical operations enhances the feasibility and safety of pandemic triage and segregation. Tabletop discussion avoids the situation where workflow is impeded due to unforseen and unaddressed infrastructural limitations.

Conclusion: Thoughtful clinic design during peacetime supports effective pandemic response, protects patients and staff, and strengthens primary care resilience.

(2) Soonchunhyang University, Cheonan, Corée (République de)
(3) Hwasung Medi-Science University, Hwaseong, Corée (République de)
(4) Cha University, Seongnam, Corée (République de)

Context: Medical education is globally adopting a competency-based curriculum (e.g., EPAs, Milestones). The Korean Academy of Family Medicine (KAFM) has defined four core and 20 detailed competencies. Existing evaluation methods (exams, logbooks) are inadequate for the objective, comprehensive assessment of FM residents, especially due to frequent external rotations. An e-portfolio system is therefore proposed to systematically track and evaluate residents' continuous competency growth.

Objectives: The primary objective was to validate the suitability and content validity (CV) of the e-portfolio evaluation tools designed for FM residents' competencies through an expert panel. This validation is essential for establishing a structured, competency-based evaluation system.

Methods: A Delphi survey verified the CV of the evaluation tools against the 20 detailed competencies. Following an initial face validity review, content validity was quantitatively assessed using a closed-ended Delphi survey among 10 experienced KAFM experts. Analysis used the Content Validity Index (CVI), with a threshold of 0.6 or higher for tool adoption.

Results: The survey confirmed high CV and expert consensus for most proposed e-portfolio tools across the four competency domains. Evidence-Based Patient Care had the most tools (eight) adopted. However, all three tools for Communication-Based Care required further discussion due to assessment difficulty. Final tools were selected or modified after expert re-evaluation based on CVI results and practical feasibility.

Discussion: The developed e-portfolio tool is a significant step toward a systematic, competency-focused assessment, offering continuous, formative evaluation that promotes self-reflection. This system is crucial for overcoming the challenge of inconsistent evaluation in FM due to rotations. The high number of adopted tools for Evidence-Based Patient Care underscores its centrality. Future efforts must focus on developing objective tools for challenging areas like Communication-Based Care.

Conclusion: This study successfully validated the content validity of the e-portfolio evaluation framework for FM resident competencies, establishing a crucial foundation for an integrated system. This shift enhances the quality of residency training by enabling the systematic tracking and support of resident development, moving beyond simple documentation to a programmed, competency-based approach.

ID 1249 - Age and Gender Representation of Patients Seen by Medical Students During Primary Care Placements

Ting-Ying KUO, Hui-Fen CHIANG, Gloria YANG, Chih-Hsueh LIN, Wen-Yuan LIN

28anita10@gmail.com, Taichung, Taïwan

Context: Hospitalization for acute myocardial infarction (AMI) creates a highly receptive moment for smoking cessation, as patients often experience heightened vulnerability and motivation to change. Although cardiac rehabilitation (CR) supports lifestyle modification, limited evidence examines the impact of inpatient CR on early cessation outcomes. This study evaluated whether participation in inpatient CR was associated with higher six-month smoking cessation among hospitalized AMI smokers.

Objectives: To assess the association between inpatient CR participation and six-month smoking cessation using a two-year retrospective cohort.

Methods: A two-year retrospective cohort included 369 hospitalized AMI smokers (2024–2025). Six-month cessation was defined as self-reported abstinence or expired carbon monoxide (CO) <10 ppm. Patients were grouped into CR (n=210) and non-CR (n=159). Cessation outcomes were compared using Chi-square and Fisher's exact tests.

Results: The CR group demonstrated a significantly higher cessation rate (43.8%) than the non-CR group (30.8%) (χ^2=5.93, p=0.0149; Fisher p=0.0128). A stronger effect observed in 2025 suggests that improvements in workflow, educational consistency, or patient engagement may influence effectiveness.

Discussion: These findings suggest that inpatient CR may serve as an effective early-phase behavioral intervention for AMI smokers. The structured education and motivational reinforcement provided during hospitalization may strengthen cessation efforts. Embedding CR-led counseling during hospitalization may provide a scalable model for secondary prevention. The association observed may also be partially influenced by unmeasured behavioral or psychosocial factors. Although unadjusted, the findings provide an important signal worthy of further controlled analyses. Future studies incorporating multivariable adjustment or propensity matching could further clarify the causal impact of inpatient CR on cessation outcomes.

Conclusion: Inpatient CR was significantly associated with higher six-month smoking cessation. Integrating structured CR-based counseling into routine AMI care and strengthening continuity between hospital services and primary care follow-up may enhance long-term cessation outcomes and support secondary prevention.

ID 1602 - From Theory to Practice: Building Sustainable Healthcare into Medical Training

Gabrielle LISEMBARD [(1)] , Quentin TONEGUZZO [(2)]

(1) Ufr3s, Grand Fort Philippe, France
(2) Ufr3s, Lille, France

Context: The World Health Organization (WHO) recognizes that compulsive sexual behaviors can harm individuals' mental, social, and physical health. Sexual addiction is a behavioral disorder that is often underestimated. Although its prevalence has been documented in other countries, few studies have been conducted in France, particularly in the northern regions.

Objectives: This study aims to determine the prevalence of sexual addiction in three multidisciplinary health centers in Northern France and to explore associated sociodemographic and behavioral factors.

Methods: This was an observational study conducted in three health centers located in urban, semi-urban, and rural areas. The PEACCE test, a validated tool for screening sexual addiction, was used. A sociodemographic questionnaire was administered to gather information on age, sex, relationship status, the use of the internet in sexual routines, and family history of addictions.

Results: A total of 334 adults, mostly women (68.9%), participated. The prevalence of sexual addiction was 5.1% in the overall sample. Prevalence was higher among men (6.7%) than women (4.3%). The use of the internet in sexual routines, a family history of behavioral addictions such as gambling, and a history of eating disorders (EDs) were associated with higher rates of sexual addiction.

Discussion: The results show a prevalence of sexual addiction that is lower than that found in other international studies. The study also confirms that internet use plays a key role in the intensification of compulsive sexual behaviors, a particularly relevant phenomenon. A major strength of this study lies in the use of a recognized test and a rigorous methodology. Its limitations include reporting and participation biases.

Conclusion: The difference in prevalence between men and women and the impact of family history

highlight the importance of targeting at-risk groups in order to develop prevention strategies.

Primary Care, Ávila, Ávila, Espagne

Context: Osteoporosis is a chronic, degenerative, and progressive disease that affects bone architecture, leading to decreased bone mineral density (BMD). All of this increases the risk of fractures, especially in postmenopausal women and older adults.

Methods: A 68-year-old woman presents with dorsal low back pain of several months' duration, causing significant functional impairment. She has a 20 pack-year smoking history and reports no fever or constitutional symptoms. Physical examination reveals dorsal kyphosis and pain on palpation of the spinous processes, with negative Lasègue and Bragard tests. A lateral spine X-ray shows vertebral wedging at L3. Diagnosis: vertebral fragility fracture secondary to osteoporosis. Differential diagnosis: primary bone tumor, metastasis, osteomyelitis. Treatment with teriparatide 20 micrograms/80 microliters daily via subcutaneous injection is initiated.

Originality: This case stands out for the early identification of a vertebral fragility fracture in a patient with initially nonspecific symptoms, which allowed for prompt initiation of anabolic treatment. Unlike what is commonly reported in the literature, where diagnostic delay is frequent, the careful clinical evaluation and suspicion of osteoporosis in the presence of risk factors—such as smoking and age—enabled a rapid and appropriate approach.

Lessons learned and future implications: Early detection of fragility fractures in patients with risk factors improves outcomes. This case highlights the importance of clinical suspicion and early treatment to prevent additional fractures.

Discussion: Some rheumatology societies, such as ESCEO–IOF, consider vertebral or hip fractures in individuals over 50 years old to be a diagnosis of established osteoporosis, even without densitometry. In patients with risk factors such as low body weight, smoking, or alcohol use, starting preventive treatment is recommended.

Conclusion: Teriparatide is an agonist of parathyroid hormone receptors and is a good option for selected cases. In a postmenopausal patient with low back pain and osteoporosis risk factors, fragility fracture should be considered in the differential diagnosis Keywords: "Fragility fracture", "Osteoporosis", "Teriparatide".

ID 1021 - Effect of long-term use of atorvastatin versus rosuvastatin on renal function and cardiometabolic parameters

Alexandra TOPA, Sergiu MATCOVSCHI, Natalia ZARBAILOV

Nicolae Testemitanu State University Of Medicine And Pharmacy, Chisinau, Moldova (République de)

Context: Hypertension is the leading modifiable cardiovascular risk factor and a major cause of morbidity. In XXX, 34.8% of adults are hypertensive, but 43.2% receive no antihypertensive therapy and only 13.4% achieve blood pressure (BP) control. Although behavioral, psychological and social determinants influence BP outcomes, primary care practice remains largely biomedical and contextual data from XXX are limited. This study addresses the gap by evaluating biopsychosocial determinants for BP control to inform personalized decision-making in XXX primary care.

Objectives: To characterize biopsychosocial profiles of hypertensive patients and identify determinants associated with BP control.

Methods: A cross-sectional study was conducted in XXX primary health care (Dec 2021–Mar 2024). Adults aged 18–75 years with confirmed hypertension were included; acute cardiovascular diseases, severe psychiatric illness, terminal disease, or inabilities to consent were excluded. Family doctors recruited participants from 26 Health Centres, ensuring national, regional, and urban–rural representation. Biopsychosocial assessment used validated tools: WHO STEPS (adapted), GAD-7, PHQ-9, and Hill-Bone Scale. Clinical measures included physical examination, medical history and recent lab data. Data were analyzed in PSPP v.2.0.0. using descriptive statistics and multivariable logistic regression (OR, 95% CI, $p<0.05$).

Results: Among 426 participants (mean age 60.9±9.7; 51.6% women), 26.5% achieved target BP, while 73.5% were uncontrolled. BP control did not differ by sex, age group, income, comorbidity burden, anxiety (p=0.622), or depression (p=0.794). Urban residence doubled the odds of BP control vs rural (OR=0.50, 95% CI 0.32–0.78; p=0.002). Controlled BP was associated with lower salt intake, avoiding added table salt, reduced sugary drink consumption (all p<0.001), active commuting (p=0.006), and alcohol reduction for health reasons (p=0.008). Adherence strongly differentiated groups: higher Hill-Bone scores (p=0.007) and fewer missed doses or refills (p<0.001–0.021).

Discussion: Evidence from primary care settings shows that psychosocial factors and adherence play a key role in hypertension control (Sandoval et al., 2018), and similar trends have been reported in XXX (Brînduşe et al., 2024).

Conclusion: Biopsychosocial profiling identified lifestyle behavior, treatment adherence and rural–urban differences as key determinants of BP control. Embedding structured biopsychosocial assessment into routine family practice may support personalized decisions and targeted interventions.

ID 1450 - Are we protecting our renal patients? Low penetration of SGLT2 inhibitors ina primary care cohort with objective renal damage

Anees ALYAFEI, Aysha HUSSEIN, Sara AL ABDULLA

Primary Health Care Corporation, Doha, Qatar

Context: Digital health technologies integrating biometric feedback and personalized coaching are increasingly utilized to manage non-communicable diseases (NCDs), yet their comparative efficacy remains unclear.

Objectives: To evaluate the effectiveness of digital interventions incorporating real-time biometric feedback and tailored coaching on clinical and behavioral outcomes in adults with lifestyle-related NCDs.

Methods: A systematic search was conducted in PubMed, Embase, Cochrane Library, and Web of Science up to April 2025. 17 studies (14 RCTs, and 3 non-RCTs) involving 3,931 adults (aged 18–84 years) with NCDs (e.g., diabetes, hypertension) that assessed interventions using biometric feedback (e.g., wearables) combined with personalized coaching were included. Primary outcomes were glycemic control (HbA1c), blood pressure (SBP, DBP), depressive symptoms, and body mass index (BMI). Secondary outcomes included physical activity, sleep quality, and medication adherence. Meta-analyses used random-effects models for pooled standardized mean differences (SMDs), with subgroup analyses by intervention duration. Risk of bias was assessed using the ROB 2.0 tool.

Results: Seventeen studies (n = 3,931 participants) were included. Digital interventions significantly improved HbA1c (SMD = −0.26), DBP (SMD = −0.14), and BMI (SMD = −0.52). SBP reduction was non-significant overall but significant in long-term subgroups (SMD = −0.24). Improvements were also observed in depression (SMD = −0.30), physical activity (SMD = +0.30), and sleep quality (SMD = +0.63). Subgroup analyses revealed duration-dependent effects for BMI and SBP. Publication bias appeared low for most outcomes.

Discussion: Digital interventions combining real-time biometric feedback with personalized coaching showed consistent benefits for glycemic control, blood pressure, BMI, and psychological well-being. Improvements in physical activity and sleep suggest broader lifestyle impacts. Duration-dependent effects indicate that longer interventions yield stronger cardiometabolic outcomes. These findings support integrating tailored digital tools into primary care to enhance NCD self-management. However, heterogeneity across studies and limited long-term evidence highlight the need for future trials evaluating sustainability, equity, and implementation in routine practice.

Conclusion: Digital interventions combining real-time biometric monitoring and personalized coaching exhibited consistent, moderate benefits across clinical and behavioral NCD outcomes. These findings support the integration of tailored digital tools into NCD self-management strategies. Future trials should assess long-term sustainability and equity.

Camps Blancs-Primary Care Center, Instituto Catalán De La Salud, Sant Boi De Llobregat., Barcelona, Espagne

Context: The doctor–patient relationship is a fundamental pillar of healthcare. It is based on effective communication, trust, and mutual respect—elements that are essential for understanding the patient's needs, establishing an appropriate diagnostic and therapeutic plan, and ensuring high-quality care.

Methods: However, achieving this relationship is not always easy. Language barriers, cultural differences, and specific beliefs about health and illness can lead to misunderstandings, complicate the process of taking a medical history, and affect both treatment adherence and health outcomes.

Originality: This situation is clearly evident in the health center where we work, located in XXX. This neighborhood, known as XXX during its construction, was created in 1968 to accommodate immigrants from rural areas and from southern XXX, offering them dignified housing. Over time, the demographic composition has not changed significantly, and today there is a high proportion of residents of foreign origin, with diverse languages, cultures, and beliefs. As a result, we frequently encounter a significant language barrier and certain cultural specificities that make communication challenging when these patients come to the family medicine consultation. These difficulties can compromise the understanding of the reason for consultation, the transmission of health information, and adherence to treatment.

Lessons learned and future implications: Given this reality, as healthcare professionals we must know and apply various techniques and tools that facilitate communication.

Discussion: Continuous training is essential for updating our knowledge, developing intercultural competencies, and improving our communication skills in an increasingly diverse environment. In this context, digital communication tools play a key supporting role. The use of assisted translation platforms, telephone or video interpretation services, multilingual health applications, and digital visual resources can significantly reduce language barriers.

Conclusion: Effective communication in multicultural healthcare promotes equity, fraternity, and liberty. By addressing language and cultural barriers, we ensure equal access to care (equity), build trust and mutual respect between patients and healthcare professionals (fraternity), and empower patients to make informed decisions about their health (liberty). Continuous training, cultural competence, and digital communication tools are key to achieving these values, enabling healthcare systems to serve diverse communities fairly, respectfully, and inclusively.

ID 59 - Profiles and care pathways at the XXX Women's Home : a descriptive retrospective study

Nolwenn VAN DER WINDT, Naïs CORSI

Université Clermont Auvergne, Clermont Ferrand, France

Context: Child abuse is responsible for clinical signs that are often little known, leading to an underestimation of violence. One billion children worldwide are victims of violence according to UN agencies.

Objectives: The objective of this study is to identify the clinical signs of abused children consulting in primary care.

Methods: A systematic review was conducted in the PubMed, Cochrane, PsycInfo, Embase, and Cinahl databases from 1996 to January 2024. The studies included focused on children aged 0 to 18 who were victims of abuse and consulting in primary care.

Results: Of the 3,811 articles found in the databases, 19 were included in the review. Signs of physical trauma included fractures, bruises, burns, genital and neurological injuries. Somatic symptoms in children may include abdominal pain, persistent non-specific symptoms, and atopic manifestations such as eczema or asthma. The psychological symptoms identified were depression, despair, and anxiety. Abuse is also associated with behavioral disorders (externalizing or internalizing behaviors) and developmental delays (language, learning, and social interaction disorders).

Discussion: Child abuse can appear in many different ways. That is why it is hard to identify in primary care. The studies included have limits: small and varied samples, different definitions of primary care. Many relied on self-reported data and some lacked complete information, which also reduced precision. Despite this, the results are consistent with previous publications showing links between abuse and physical injuries, psychological symptoms, somatic complaints, or developmental delays. Primary care remains a crucial place to detect these situations early, but practitioners may

struggle with doubts, emotional discomfort, and unfamiliarity with reporting procedures. More training and support would help them feel better equipped to act.

Conclusion: There are few articles studying the clinical signs of child victims of violence consulting in primary care. These children may present with various clinical signs (physical trauma, pain, atopy, psychological disorders, behavioral disorders, developmental delays) that highlight the importance of considering abuse.

ID 694 - Article title: Identifying clinical signs of child abuse in primary care : a systematic review

Raj THAKKAR

Primary Care Cardiovascular Society, High Wycombe, Royaume-Uni

Context: Chronic obstructive pulmonary disease (COPD) is associated with increased risk of cardiovascular diseases including atherosclerotic CVD (ASCVD), stroke, heart failure (HF) and atrial fibrillation (AF).(1) Patients with COPD may therefore be eligible for primary prevention of ASCVD by offering lipid lowering therapy (LLT).

Objectives: This real-world primary care-based service evaluation assessed the feasibility of offering LLT during a routine COPD review. It also considered the quantum of patients eligible for LLT, and LLT naive patients who accepted the offer of medicines to reduce their ASCVD risk.

Methods: After educating respiratory nurses, LLT naive patients with COPD were offered therapy during routine nurse-delivered COPD reviews. ASCVD risk was discussed with patients at the time of the review. Patients wanting LLT were directed either to the primary care pharmacist or GP for a prescription, or further discussion and prescription if mutually agreed. Patients were also assessed for undiagnosed AF and HF.

Results: Of the first 58 patients reviewed in the programme, 37 (64%) were already taking LLT. All 21 patients not taking LLT were offered therapies to reduce their lipids with a view to ASCVD risk reduction. 10 of the 21 patients were prescribed LLT, 9 declined LLT and 2 requested further blood testing. The opportunistic approach increased LLT prescribing in this cohort by 17%.

Discussion: A significant number of patients with COPD were already prescribed LLT. This would be expected given the shared risk factors with ASCVD. However, a proportion of individuals who, by virtue of having COPD, were for eligible LLT to reduce their elevated ASCVD risk.

Conclusion: Routine primary care-based COPD reviews are well placed to offer LLT to patients to potentially reduce the risk of atherosclerotic diseases. We advise routine proactive CVD risk reduction as standard practice during COPD reviews in the primary care setting.

(6) Resmed Clinical Engagement, Bales, Suisse
(7) Grenoble Alpes University, Grenoble, France

Context: Obstructive Sleep Apnea (OSA) is a prevalent yet underdiagnosed sleep disorder, contributing to substantial cardiometabolic and neurocognitive morbidity. Despite its public health importance, long-term projections for OSA in western Europe are limited, leaving future trends largely uncertain. The EU-5 countries, France, Germany, Italy, Spain, and the United Kingdom, face rising obesity rates and aging populations, all of which influence future OSA burden.

Objectives: To project the 30-year burden of OSA across EU-5 countries by estimating future prevalence, absolute case numbers, and severity distribution, and to quantify the drivers of burden growth to inform primary care planning and public-health strategy.

Methods: An open-cohort dynamic Markov model was developed as forecasting framework and applied to adults aged 30–69 years in the EU-5 from 2020 to 2050. Country-specific demographics (age,

sex, fertility), body mass index (BMI) distributions, and baseline OSA prevalence informed model initialization. OSA incidence and progression across apnea-hypopnea index (AHI) thresholds (≥5, ≥15, ≥30) were modeled using regression equations linking age, sex, and BMI to AHI progression. Outputs included OSA prevalence, absolute case counts, and mild, moderate and severe disease burden.

Results: Across the EU-5, OSA prevalence (AHI ≥5) is projected to increase from ~36% in 2020 to ~54% in 2050. Prevalence rises in all countries, with Italy and Spain showing the steepest proportional growth. Despite population contraction in Germany and Italy, absolute numbers of moderate-to-severe OSA cases (AHI ≥15) continue to rise, while France and the UK are projected to experience increases in both prevalence and total cases. Compared to mild and moderate OSA, severe OSA (AHI ≥30) is estimated to exhibit the most proportional growth across all countries.

Discussion: The projected rise in OSA across western Europe is driven predominantly by modifiable metabolic risk and an aging population. These trends highlight the central role that general practitioners will need to play in the early identification, risk stratification, and long-term management of OSA.

Conclusion: By 2050, more than half of EU-5 adults may have OSA. Scalable screening, diagnostic, and management strategies, anchored in primary care, are urgently needed, alongside coordinated obesity and cardiometabolic risk-reduction efforts across western Europe.

Corresponding author: Elroy Boers, elroy.boers@resmed.com

ID 658 - Medico-Economic Interest of POCUS in General Practice for First-Trimester Pregnancy Bleeding and Abdominal Pain

Capucine PAYRE [(1)], Mariela SKENDI [(1)] , Morgane MICHEL [(2)]

(1) Sorbonne Université, Paris, France
(2) Université Paris Cité, Paris, France

Context: Point-of-Care Ultrasound (POCUS) is increasingly utilized by general practitioners (GPs) to address specific clinical questions. A preliminary study (ECHO-MG) showed POCUS modifies diagnostic hypotheses, strengthens diagnostic certainty, and reduces the need for supplementary examinations, suggesting a potential for greater efficiency in the healthcare system.

Objectives: To evaluate the potential economic benefit of POCUS in managing first-trimester pregnancy bleeding and/or abdominal pain (a frequent and often anxiety-provoking consultation reason) by calculating and comparing the associated management costs with and without the use of POCUS.

Methods: This medico-economic study is a cost-minimization analysis, based on the assumption that management pathways with and without POCUS are clinically equivalent. Resource consumption data were derived from anonymized data collected via an online questionnaire from the observational, prospective, cross-sectional, and multicenter study (ECHO-MG), which was conducted in France between October 2023 and June 2024. Data were recorded before and after POCUS, detailing the indication, diagnostic hypotheses, and planned care pathway. The analysis was conducted from two perspectives: the National Health Insurance (NHI) and the societal perspective.

Results: The sample comprised 37 patients. From the NHI perspective, the total cost decreased from €2,735.35 before POCUS to €2,454.68 after POCUS, averaging a €7.59 saving per patient. From the societal perspective, costs decreased by an average of €14.43 per patient. Crucially, these cost differences were not statistically significant (Wilcoxon test for paired samples: $p = 0.23$ for NHI; $p = 0.32$ for societal).

Discussion: The observed cost reductions, while not statistically significant, suggest a trend towards economic efficiency. It is hypothesized that costs, particularly in the non-POCUS group, may have been underestimated. Furthermore, the lack of statistical significance is likely attributable to the limited statistical power resulting from the small sample size (n=37). POCUS streamlines the diagnostic process for this potentially urgent and anxiety-provoking condition, leading to resource optimization and higher satisfaction for both practitioners and patients.

Conclusion: The integration of POCUS into general practice potentially reduces the direct management costs for first-trimester pregnancy bleeding and/or abdominal pain from both the health insurance and societal perspectives, supporting POCUS as an efficient practice for optimizing the care pathway.

C.s.barrio Peral, Cartagena, Espagne

Context: Restless Legs Syndrome (RLS) is a common yet underdiagnosed neurological disorder characterized by disabling symptoms and a significant deterioration in quality of life. Approximately 2–3% of the population has moderate to severe manifestations, turning its management into a challenge in primary care settings. KEYWORDS Restless legs syndrome; primary care; quality of life; therapy.

Methods: We report the case of a 61-year-old male with bilateral radiculopathy and multiple spinal surgeries, who presented severe nocturnal symptoms including an uncontrollable urge to move his legs, intense paresthesias, and long-standing chronic insomnia. Following complementary diagnostic testing and assessment using the IRLS scale, our patient was diagnosed with severe RLS and received first-line pharmacological therapy—including benzodiazepines, anticonvulsants, and antidepressants—with minimal to no clinical response.

Originality: Based on international clinical guidelines and within a primary care setting, treatment was initiated with prolonged-release oxycodone/naloxone, an infrequently used therapy in this context but supported by evidence for refractory RLS. After several weeks of dose titration, our patient achieved marked clinical remission, along with solid improvement in sleep patterns.

Lessons learned and future implications: Assessment using the EuroQol-5D scale before and after treatment demonstrated a remarkable improvement in quality of life, evolving from severely impaired functioning to near-normal status. The treatment was well tolerated, with no relevant adverse effects reported. These findings support the use of opioid-based therapies—typically reserved as last-line options—in advanced cases.

Discussion: This case illustrates a complex presentation of RLS coexisting with somatosensory symptoms, chronic insomnia, and prolonged medication exposure, with limited response to first-line therapies. The eventual need for opioid therapy aligns with current evidence-based strategies for resistant RLS, particularly in patients with underlying structural pathology.

Conclusion: Primary care plays a key role in handling refractory RLS by applying evidence-based interventions. With appropriate monitoring, the oxycodone/naloxone combination may represent an effective therapeutic option. A proactive and multidisciplinary approach is essential to optimize the management of complex clinical scenarios.

Context: Prenatal care is a central strategy for reducing maternal and neonatal morbidity and mortality, and Brazil has undergone major structural and demographic changes in the last three decades, including declining fertility, reduced numbers of live births, and persistent regional inequalities in access and quality of prenatal care. The ratio between the number of prenatal consultations and live births represents a synthetic indicator of gestational follow-up intensity and is sensitive to changes in system organization, primary care expansion, financing, and socioeconomic disparities.

Objectives: To analyze temporal trends in the ratio of prenatal consultations to live births in all Brazilian federative units from 1994 to 2024, identifying inflection points and regional inequalities.

Methods: An ecological time-series study was conducted using secondary data from SINASC (Live Birth Information System) and SIA/SUS (Outpatient Information System of the Unified Health System), accessed via DATASUS, covering all 27 federative

units from 1994 to 2024. For each state-year, the ratio of prenatal consultations to live births (NCP/NV) was calculated. Descriptive analyses included means, standard deviations, and absolute and relative variations. Temporal trends were evaluated using Joinpoint Regression (version 5.2.0.0), estimating Annual Percent Change (APC) and Average Annual Percent Change (AAPC) with 95% confidence intervals and $p < 0.05$.

Results: Nationally, the NCP/NV ratio increased from 0.38 in 1994 to 1.45 in 2024 (+281.6%). Three national phases were identified: accelerated growth (1994–1998), sustained expansion (1998–2015), and sharp decline (2015–2020), followed by stabilization (2020–2024). States showed heterogeneous patterns: long-term increases in Mato Grosso, Maranhão, São Paulo, and Rio de Janeiro; declines in Alagoas, Amazonas, and Roraima; and marked inflection after 2013–2016 across the North and Northeast.

Discussion: The trends reflect interactions between structural advances in primary care—especially ESF expansion and Rede Cegonha—and vulnerabilities linked to fiscal austerity, reduced federal financing, and the COVID-19 pandemic, which disproportionately affected weaker health systems.

Conclusion: Despite national progress, Brazil exhibits persistent regional inequalities in prenatal care intensity, underscoring the need for stable financing, strengthened primary care teams, and territorially tailored strategies to ensure equitable and continuous prenatal follow-up.

Context: Obesity has reached unprecedented levels globally, becoming one of the main drivers of cardiometabolic disease in current practice. Its rising prevalence is associated with earlier onset of Type 2 Diabetes (T2D), dyslipidemia, hypertension, and sleep apnea. This case illustrates the profound health impact that substantial weight loss can achieve.

Methods: A 37-year-old male, ex-smoker, with probable childhood asthma, presented in 2017 with severe obesity (maximum 187 kg, BMI around 65 kg/m²), poorly controlled T2D (HbA1c 13.7 %), dyslipidemia, and severe sleep apnea (AHI 70/h). He required insulin therapy, CPAP and required multiple antihypertensive medications. He underwent bariatric surgery in 2019 and progressively reached 87 kg by 2024 (around 100 kg loss). Follow-up was shared between primary care, endocrinology, and pulmonology.

Originality: This case demonstrates how addressing obesity as a chronic disease can reverse several cardiovascular risk factors simultaneously. In an era where obesity shapes much of the cardiovascular morbidity profile, such results emphasize the value of structured management.

Lessons learned and future implications: The patient achieved T2D remission, marked improvement in lipid profile, and a significant reduction in sleep apnea severity (AHI 70/h → 18/h) allowing CPAP withdrawal. Blood pressure and respiratory symptoms normalized with deprescribing. These changes highlight the extensive systemic benefits of significant weight loss. Primary care is essential for early detection, long-term monitoring, and coordination of multidisciplinary management pathways.

Discussion: While bariatric surgery initiated rapid clinical improvement, sustained weight loss and preservation of cardiometabolic benefits depend largely on ongoing primary care follow-up. Reinforcement of lifestyle habits, psychological support, and timely medication adjustments are key to preventing relapse. Given the current obesity epidemic, primary care must act as the anchor of continuity, ensuring long-term stabilization and protection of achieved health gains.

Conclusion: Primary care plays a central role not only in identifying candidates for obesity treatment but also in maintaining and protecting the substantial health benefits derived from major weight loss. In this patient, the approximately 100 kg reduction produced a profound decrease in cardiovascular risk and a reversal of multiple chronic conditions. Ensuring that these gains persist over time is one of the most impactful contributions of primary care to long-term patient health.

ID 14 - Barriers and Enablers of Seeking Mental Health Services among Adult Saudi Residents with and without a Perceived Need - A Survey

Jiho CHOI, Tai Shun YEN

Department Of Family Medicine, Inha University College Of Medicine, Incheon, Corée (République de)

Context: The availability of glycosylated hemoglobin(HbA1c) measurement has been one of the major advances in diabetes care. Recently, HbA1c not only provides a reliable measure of diabetes but also predict disease related to insulin resistance such as hypertension, and heart disease. As the average life expectancy increases and people interest in the quality of life of individuals have started to pay much attention.

Objectives: This study was analyzed the relationship between HbA1c and Health Related Quality of Life(HQoL) from Korean adult age over 19.

Methods: We included 5,796 male and female who participated in the Korean National Health and Nutrition Examination Survey(KNHANES) from 2018. HbA1c level was separated by 6.0% in each group, The Euro quality of life-5 dimension(EQ-5D) questionnaire was used to measure HQoL. A multiple logistic regression analysis was performed to examine the association between HbA1c and HQoL.

Results: The EQ-5D index score of the lower than 6.0% HbA1c group was significantly lower than of the upper than 6.0% group. After adjusting for multiple covariates, the odds ratio (95% confidence interval, [CI]) for Anxiety/depression issues was 1.18 (95% CI, 1.017-1.365) in male and Self-care issues was 1.22 (95% CI, 1.004-1.472) in female; however, in other issues the difference was not statistically significant for male and female.

Discussion: Insulin resistance refers to a state in which insulin receptor action is reduced in the absence of insulin, and this phenomenon has been reported as a cardiovascular-independent risk factor, and the higher the insulin resistance, the lower the quality of life.

Conclusion: HbA1c was associated with reduced quality of life. It is important to control HbA1c levels to improve HQoL.

ID 887 - Burnout Among Slovenian General Practitioners: Emerging Patterns and Pathways to Prevention

Assunta MAIELLO, Francesco MONTANINO

Cfsmg Regione Campania, Napoli, Italie

Context: Within the framework of the Specific Training Course in General Practice/Family Medicine (CFSMG) of the Campania Region, the new educational program of the course—structured in accordance with DGRC no. 53 of 08.02.2024 - BURC no. 18 of 19.02.2024—was developed in alignment with the specific competencies of the discipline identified by WONCA (2022) and based on the need for an educational design grounded in these competencies, aimed at achieving “relevance” (Guilbert, 2002).

Methods: All activities within the Central Seminars, held at the Regional Educational Center located in So.Re.Sa. spa, were redesigned according to the Milestones model. This model enables trainees to progress through the four learning levels outlined in Miller’s pyramid (1990), particularly within the thematic areas of greatest epidemiological relevance for General Practice. To enhance teaching effectiveness, each instructor is supported by a Professional Support Figure (FPS), whose role is to participate in the lesson and provide preliminary consultation regarding lesson organization and the most effective interactive teaching methodologies.

Originality: Additionally, new modules using high-fidelity simulation with manikins were introduced, led by expert instructors and limited to a maximum of 25 participants per seminar.

Lessons learned and future implications: Trainee evaluation is conducted through two annual assessments: a training-progress test using MCQs, and an analysis of their personal portfolio, which contains tutor evaluations and a “competency simulation” session. This session is followed by feedback from the faculty board and tutors, and focuses on competencies such as: welcoming and managing patient needs, redefining health needs, the ability to integrate EBM and NBM, and the capacity to implement an efficient organizational model.

Discussion: A further aspect of the ongoing quality-improvement process involves training the trainers (General Practice tutors) through a structured regional training program that uses

interactive teaching and role-playing to help tutors develop greater mastery in promoting the specific competencies of the General Practitioner in trainees.

Conclusion: We believe that the training model developed in Campania could serve as a virtuous example of continuous improvement in specific training for general medicine.

ID 1002 - Clinical Simulation in Managing Anxiety Crisis in Primary Care Patients

Youngjae KIM [(1)] , Seonmee KIM [(2)]

(1) Kyobo Life Healthcare Center, Seoul, Corée (République de)
(2) Korea University Guro Hospital, Department Of Family Medicine, Seoul, Corée (République de)

Context: Although numerous studies examined the association between obesity and colorectal cancer, comparatively less research has focused on the relationship between weight change and physical activity.

Objectives: A research study was conducted to examine the association between weight change (based on Weight and Body Mass Index (BMI)) and cancer incidence, utilizing 10 years of nationwide health screening data from the National Health Insurance Service (NHIS).

Methods: This study used health check-up data from the National Health Insurance Service. Participants aged 20–79 years who underwent health check-ups between 2004 and 2007 and again 10 years later were included. Differences were analyzed by dividing the weight change into groups that increased or decreased by 5%, 5%–20%, and 20% or more.

Results: Among men, a 20% increase in body weight was significantly associated with a higher risk of colon cancer (hazard ratio [HR], 1.26; 95% confidence interval [CI], 1.05–1.52), even among those who exercised on at least 3 days a week. In contrast, women who had undergone a weight loss of more than 5%–20% of their body weight were found to have a significantly reduced risk of colon cancer (HR, 0.69; 95% CI, 0.50–0.93). However, women who reduced their exercise frequency from 3 or more days per week to less than 3 days per week experienced a weight gain of 20% or more, which was associated with a higher risk of developing colorectal cancer (HR, 1.82; 95% CI, 1.07–3.12)

Discussion: Previous research largely addressed the effects of weight gain and obesity; this study, in contrast, calculated the incidence risk resulting from weight loss. Nevertheless, additional analysis is required to account for differences in Socioeconomic Status (SES), dietary factors, and the presence of comorbidities (related diseases).

Conclusion: These findings highlight the association between recent increases in colon cancer incidence and weight management, emphasizing the importance of maintain a healthy weight in mitigating obesity-related cancer risk

ID 1673 - Evolution of professional burnout in family doctors from 2016 to 2025.

Mooyoung KIM

Seoul Metropolitan Bukbu Hospital, Seoul, Corée (République de)

Context: As Korea's population rapidly ages, primary care clinics are increasingly expected to contribute to community-integrated care, including home-visit medical services. However, how physicians understand these roles and what barriers they perceive in urban settings remain insufficiently explored.

Objectives: To compare awareness of community-integrated care and perceived barriers between primary care physicians with and without home-visit experience in Seoul.

Methods: A cross-sectional online survey was conducted among 400 primary care physicians. The questionnaire assessed demographic characteristics, participation in integrated-care programmes, Likert-scale (1–5) measures of awareness and service necessity, and perceived barriers. Physicians were categorised based on home-visit experience. Descriptive statistics were calculated, and Welch's t-tests were used to analyse between-group differences.

Results: Of the respondents, 111 (27.7%) had home-visit experience and 289 (72.3%) did not. Compared with non-experienced physicians, those with home-visit experience showed significantly higher scores for community-integrated care awareness (2.98 ± 1.34 vs 2.28 ± 1.14, $p < 0.001$),

perceived need for integrated care (3.86 ± 1.12 vs 3.43 ± 1.07, p = 0.001), perceived necessity of home-visit services (4.02 ± 1.10 vs 3.43 ± 1.17, p < 0.001) and perceived need for discharge management (3.83 ± 1.09 vs 3.46 ± 1.16, p = 0.004). Physicians without home-visit experience consistently rated barriers—medical-liability concerns, low reimbursement, administrative complexity, workforce shortages and training needs—higher than experienced physicians, suggesting that these obstacles may reflect unfamiliarity rather than actual service difficulty.

Discussion: The findings indicate that direct exposure to home-visit care strongly shapes physicians' attitudes toward community-integrated care. The heightened perception of barriers among non-experienced physicians aligns with international evidence that limited exposure increases perceived risk and decreases engagement. Enhancing reimbursement, simplifying administrative procedures and providing coordination support may reduce these concerns. Expanding opportunities for early participation and peer learning could help narrow perception gaps and promote willingness to engage in home-visit services.

Conclusion: Home-visit experience is associated with higher awareness of integrated care and lower perceived barriers among primary care physicians in Seoul. Policy efforts to expand home-visit services should prioritise improved reimbursement, streamlined processes and supportive coordination systems. Leveraging experienced clinicians as key drivers may facilitate broader adoption of community-integrated care models in metropolitan primary care.

(2) Hospital Universitario Severo Ochoa, Leganés, Espagne
(3) Semfyc, Barcelona, Espagne

Context: Traumatic brain injury (TBI) is a leading cause of death and disability worldwide, affecting millions each year and imposing substantial social and economic burdens. Its clinical presentation ranges from mild concussions to severe, life-threatening injuries. A comprehensive understanding of the biomechanical forces involved, global epidemiological trends, and the resulting spectrum of intracranial lesions is essential for improving acute management. Advances in neuroimaging—particularly computed tomography (CT)—and the growing development of blood-based biomarkers have the potential to refine diagnostic pathways and guide early therapeutic decisions.

Objectives: This literature review aims to systematically synthesize current evidence on (1) mechanisms and epidemiology of TBI, (2) patterns of structural brain injury, and (3) the diagnostic performance and clinical utility of CT imaging and emerging biomarkers in the acute evaluation of TBI.

Methods: A systematic search of PubMed, Scopus, and Web of Science was performed for studies published between 2010-2025. Eligible articles included observational studies, clinical trials, systematic reviews, and meta-analyses addressing TBI biomechanics, incidence, classification of lesions, CT findings, or biomarker assessment. Two reviewers independently conducted screening, data extraction, and quality appraisal using standardized tools. Discrepancies were resolved through consensus.

Results: The search identified a broad and heterogeneous body of evidence. Epidemiological data revealed significant global variation, with falls being the predominant cause of TBI among older adults, while traffic-related and sports-related injuries remained more common in younger individuals. CT imaging consistently demonstrated high accuracy for detecting clinically relevant intracranial lesions. Among emerging biomarkers, glial fibrillary acidic protein (GFAP) and ubiquitin C-terminal hydrolase L1 (UCH-L1) showed the strongest diagnostic value, particularly in mild TBI, where they correlated with intracranial abnormalities and helped reduce unnecessary CT utilization. Additional markers such as S100B and neurofilament light chain (NfL) exhibited promising but variable performance across studies.

Discussion: Despite growing evidence, differences in study design, assay platforms, and clinical thresholds limit biomarker standardization. Combining biomarkers with validated clinical decision rules may improve diagnostic precision and resource allocation.

Conclusion: Current literature highlights the central role of CT in acute TBI evaluation while emphasizing the emerging contribution of blood-based biomarkers. Further large-scale, harmonized studies are needed to support their integration into routine clinical practice.

ID 1861 - Suicide Attempts in Bipolar Disorder: An Emergency at the Frontline of Primary Care

Yong Soon PARK [(1)] , Keunjoong YOO [(1)], Hye Jin KIM [(2)]

(1) Department Of Family Medicine, Chuncheon Sacred Heart Hospital, Hallym University College Of Medicine, Chuncheon, Corée (République de)
(2) Institute Of New Frontier Research, Hallym University College Of Medicine, Chuncheon, Corée (République de)

Context: Maintaining health-related quality of life (HRQoL) is a fundamental goal of primary care for ageing populations. Handgrip strength is a simple, inexpensive measure of physiological reserve, yet it remains unclear how muscle strength and resistance exercise jointly influence perceived health in older adults in community settings.

Objectives: To examine sex-specific associations between muscle strength and optimal HRQoL, and to assess whether regular resistance exercise modifies these associations.

Methods: We analysed data from 4,782 community-dwelling adults aged 65–79 years who participated in the nationally representative Korea National Health and Nutrition Examination Survey (KNHANES). Optimal HRQoL was defined as an EQ-5D index score of 1.000. Muscle strength was assessed using maximal handgrip strength (HGS), relative HGS, and dynapenia based on Asian Working Group for Sarcopenia criteria. Sex-stratified multivariable logistic regression models were fitted, including interaction terms for regular resistance exercise (≥2 days/week).

Results: Higher muscle strength was independently associated with greater odds of optimal HRQoL in both sexes. Among men, this association was strongest in those not engaging in regular resistance exercise, with significant interactions for maximal HGS (interaction adjusted odds ratio [aOR] = 1.05, 95% CI 1.01–1.09; P = 0.020) and dynapenia (aOR = 0.37, 95% CI 0.16–0.89; P = 0.027). Among women, relative HGS showed the most consistent association with optimal HRQoL (aOR = 1.09, 95% CI 1.03–1.14; P = 0.002), irrespective of resistance exercise participation.

Discussion: These findings demonstrate sex- and activity-specific pathways linking muscle strength to perceived health. In older men, insufficient participation in resistance exercise may heighten vulnerability to the adverse effects of low strength. Women, in contrast, exhibit a more stable strength–HRQoL relationship across activity levels. These insights highlight the value of tailored functional assessment and behaviour-focused counselling in primary care.

Conclusion: Muscle strength is a key determinant of HRQoL in older adults, with clear variation by sex and resistance exercise participation. Incorporating handgrip strength assessment into routine primary care and promoting strength-focused activity—particularly among less active older men—may enhance functional independence and well-being in ageing populations.

ID 2057 - From muscle pain to major depression: A case highlighting the somatic presentation of depression in primary care

Adam GUCK, Katherine BERGS, Nelly YUEN, Marlen MENDEZ-GARCIA

Jps Health Network, Fort Worth, États-Unis

Context: Behavioral health training is a core element of primary care residency education, yet its scope and emphasis vary widely across programs. Estimates indicate that at least one in four visits involves a behavioral health concern, with another quarter requiring lifestyle or behavior change counseling, highlighting the importance of these competencies. Despite guidance from national organizations, no consensus exists on which behavioral health topics should be prioritized or how competency-based training should reflect this domain.

Objectives: To assess practicing and resident family physicians' perceived importance and self-reported comfort with core behavioral medicine competencies, with the aim of informing competency-based curriculum development.

Methods: A cross-sectional survey was administered online to family physicians within 10 years of residency graduation from family medicine training programs across the United States.

Participants rated the perceived importance and their level of comfort across common behavioral medicine domains, including assessment and management of mood and anxiety disorders, interviewing skills for mental health presentations, and health behavior change counseling.

Results: Participants consistently rated high need for training in common mood conditions, particularly depression and anxiety. Strong endorsement was observed for increased training in lifestyle counseling and support of health behavior change. Physicians emphasized the importance of developing more advanced overall interviewing skills for patients with mental health concerns. While patterns of priority were similar across levels of experience, early-career physicians reported lower overall comfort levels compared to their more experienced counterparts.

Discussion: Findings highlight consistent priorities for behavioral medicine training, espcially in mood and anxiety disorder management, lifestyle counseling, and interviewing skills. Lower comfort and higher frequency as reported by physicians suggests gaps in training readiness and variability across programs. Results emphasize the need for standardized and competency-based urriculca that emphasize practical skill development and clinical application within key areas of practice.

Conclusion: Clear priorities emerged for key behavioral medicine competencies. Enhancing training in mood disorders, health behavior change counseling, and mental health interviewing may improve preparedness for primary care practice. Strengthening competency-based behavioral medicine education could reduce comfort gaps among physicians and better align training with their needs as they enter clinical practice.

Corresponding author: Adam Guck, adamguck@my.unt.edu

ID 216 - Adapted Physical Activity in Eastern Occitanie : how awareness of nearby facilities promotes written Adapted Physical Activity prescriptions

Miyen CHUA [(1)] , Goh LAY HOON [(2)]

(1) Nanyang Technological University (ntu), Singapore, Singapour
(2) NUS Yong Loo Lin School of Medicine, Singapore, Singapour

Context: Healthier SG (HSG) aims to encourage patients to manage their chronic conditions with a designated family physician. This abstract hopes to evaluate if patients with chronic conditions are incentivised to enroll in HSG due to intrinsic factors (ie. prevalence of chronic conditions) and adjust for these results by considering extrinsic factors (ie. awareness, alternative healthcare options).

Objectives: The aim is to evaluate if HSG is reaching its target audience (ie. those with chronic conditions) and the potential causes if it fails to do so.

Methods: A cross-sectional survey of 116 Toa Payoh residents was conducted in October 2025. Data collected includes participants' attitudes towards health and awareness of relevant policies. Logistic regression and basic proportion is used in analysis.

Results: Interestingly, the number of chronic diseases is negatively correlated with HSG enrollment rates, with binary regression showing (OR=0.635, 95%CI=[0.440, 0.915], p-value=0.0148). As such, further analysis is done to evaluate the correlation between chronic conditions and other factors to explain this trend. There is no significant correlation between the number of chronic conditions and HSG awareness (OR=0.951, 95%CI=[0.760, 1.188], p-value=0.657). However, 67% of those with >4 chronic conditions mainly visit hospitals, 74% of those with 2-3 chronic conditions mainly visit polyclinics and 60% of those with 0-1 chronic conditions mainly visit polyclinics.

Discussion: HSG awareness, though important, does not explain why those with more chronic conditions have a lower HSG enrollment rate. However, extrinsic factors like alternative healthcare options may contribute as HSG only applies to polyclinics and GP clinics instead of hospitals. As such, considerations can be made to expand the scope of HSG to include hospitals to better aid patients with multiple comorbidities. However, this does not explain the higher takeup rate of 31% amongst those with 0-1 chronic conditions compared to 16% for those with 2-3 chronic conditions. Hence, research should be done on other intrinsic factors like perspectives towards HSG.

Conclusion: In conclusion, HSG enrollment rate is multifactorial and in-depth studies are needed to confirm the extent to which it is affected by each factor.

ID 508 - Association between inpatient cardiac rehabilitation and six-month smoking cessation among acute myocardial infarction smokers: a two-year cohort analysis

Minjung HAN, Joo-Hyun PARK

Korea University Ansan Hospital, Ansan, Corée (République de)

Context: The association between smoking and mortality in pancreatic cancer across different clinical stages remains uncertain.

Objectives: This study aimed to evaluate the association between smoking status and all-cause mortality in patients with pancreatic cancer and to examine whether this association varies by clinical stage.

Methods: This retrospective population-based cohort study used data from four nationwide South Korean registries. A total of 9,964 adults aged ≥30 years with newly diagnosed pancreatic cancer who had received a national health screening within one year before diagnosis between 2012 and 2017 were included. Smoking status was self-reported and categorized as current, former, or never smoker. All-cause mortality was analyzed using multivariable Cox proportional hazards models adjusted for sociodemographic, lifestyle, and clinical factors. Subgroup analyses were performed according to the Surveillance, Epidemiology, and End Results (SEER) stage classification.

Results: Current smoking was consistently associated with higher all-cause mortality across all clinical stages (overall aHR 1.15, 95% CI 1.07-1.22; stage-specific aHRs ranging from 1.09 to 1.34). This association was especially strong in localized and regional disease (localized: aHR 1.34, 95% CI 1.10-1.64; regional: aHR 1.19, 95% CI 1.09-1.30; distant: aHR 1.09, 95% CI 1.00-1.19). Tests for interaction by stage were not significant ($p > 0.05$). Former smoking was not associated with increased mortality (overall aHR 0.96, 95% CI 0.90-1.03).

Discussion: Current smoking was independently associated with higher mortality in patients with pancreatic cancer across all clinical stages, and this association was stronger in earlier stage disease.

Conclusion: Smoking cessation may contribute to improved survival outcomes in patients with pancreatic cancer, especially in earlier stages when long-term survival potential is higher.

(1) Cs La Calzada, Gijón, Espagne
(2) Cs Bertamiráns, Santiago De Compostela, Espagne
(3) Universidade De Santiago De Compostela, Santiago De Compostela, Espagne

Context: Thyroid hormones play a key role in metabolism and hematopoiesis. While clinical thyroid disease is well studied, the hematological impact of subclinical thyroid dysfunction is less understood, and existing findings are inconsistent. Early identification of subtle abnormalities may help anticipate progression to overt disease.

Objectives: The study aimed to analyze variations in hematological parameters among adults with subclinical hypothyroidism or subclinical hyperthyroidism in a general population.

Methods: A cross-sectional study was conducted using data from the AEGIS cohort in the rural municipality of A Estrada (Galicia, Spain). A stratified random sample included 1516 participants aged ≥18 years. After excluding individuals with known thyroid disease, abnormal T4 levels without diagnosis, or missing data, 1271 participants were classified as euthyroid, subclinical hypothyroid, or subclinical hyperthyroid according to standard TSH and free T4 thresholds. All participants completed a structured questionnaire covering demographics, lifestyle, comorbidities, and physical activity (IPAQ). Fasting blood samples were analyzed for thyroid function and hematological parameters. Statistical analysis included chi-square tests and sex-adjusted linear regression models.

Results: Thyroid disease prevalence was 9.43%, while subclinical dysfunction accounted for 6.8% (5.31% hypothyroidism; 1.49% hyperthyroidism). Subclinical hypothyroidism was more frequent in women (66.7%). Smoking status showed significant associations with thyroid function. Among hematological markers, only hematocrit was significantly lower in the subclinical hypothyroidism group. In sex-adjusted regression analyses, red blood cell count, hemoglobin, hematocrit, and platelet count increased with higher free T4 levels. Men showed higher values in red cell indices, while women had higher platelet counts. No meaningful

associations were found for leukocyte count, MCV, MCH, or MCHC.

Discussion: Findings confirm a low but notable prevalence of subclinical thyroid dysfunction, especially among women, consistent with prior epidemiological data. The hematological impact of subclinical disease appears modest, though the positive correlation between free T4 and several erythroid parameters aligns with known physiological effects of thyroid hormones on erythropoiesis.

Conclusion: Subclinical thyroid dysfunction is relatively common and exhibits sex-specific patterns. Hematocrit is the only hematological parameter significantly reduced in subclinical hypothyroidism, while erythroid and platelet indices rise with increasing free T4. These results may support early identification of subtle hematological changes in mild thyroid dysfunction.

ID 845 - Effectiveness of Structured Physical Exercise in Improving Knee Osteoarthritis Outcomes at a Primary-Care Wellness Center

Tina ZAVIDIĆ [(1)] , Ema DEJHALLA [(2)], Branislava POPOVIĆ [(1)], Đino LOVRINIĆ [(3)]

(1) University Of Rijeka, Rijeka, Croatie
(2) Medical Centre For Occupational Health Rijeka, Rijeka, Croatie
(3) Istrian Helath Centers, Pazin, Croatie

Context: Aortic stiffness, assessed by estimated pulse wave velocity (PWV), has recently been linked to knee osteoarthritis (KOA) independent of traditional cardiovascular risk factors and systemic inflammation. Novel oscillometric and ultrasound techniques have enabled non-invasive detection of vascular changes that may accompany osteoarthritic progression. Understanding whether vascular stiffness reflects KOA severity could improve risk stratification and management in primary care, particularly among postmenopausal women who represent a high-risk population.

Objectives: This study aimed to determine whether PWV can differentiate between mild (Kellgren–Lawrence [KL] 1–2) and severe KOA (KL 3–4) in primary care. Additionally, it examined whether disease severity corresponds to differences in proinflammatory status, metabolic dysregulation, and functional capacity.

Methods: A total of 225 postmenopausal women with KOA, diagnosed according to American College of Rheumatology criteria, were recruited. Exclusion criteria included autoimmune disease, hematological disorders, malignancy, neurological or psychiatric conditions, end-stage organ failure, and ongoing hormonal or anti-inflammatory therapy. All participants provided informed consent and underwent anthropometric assesment, peripheral blood sampling, BMI and SCORE2/SCORE2-OP calculation, blood pressure and PWV measurement using an oscillometric device. Functional capacity was evaluated using the 6-minute walk test, and physical activity was assessed with the International Physical Activity Questionnaire (IPAQ).

Results: PWV was significantly higher in women with severe KOA (KL 3–4: 10.53 m/s) compared with mild KOA (KL 1–2: 8.78 m/s; $p < 0.001$). A cut-off value of 8.4 m/s could distinguish mild from severe KOA (AUC 0.798, sensitivity 67.46%, specificity 76.92%, P = 0.001, measured with the Agedio device). Higher PWV correlated with older age, higher systolic blood pressure, increased waist circumference and waist-to-hip ratio, elevated fasting glucose and HbA1c, higher SCORE2/SCORE2-OP, serum uric acid, creatinine, and ESR, as well as lower eGFR. Functionally, greater stiffness was associated with severe pain, reduced 6-minute walk distance, total IPAQ score, and vigorous physical activity.

Discussion: PWV rises with KOA severity and parallels metabolic and inflammatory disturbances, suggesting a shared pathophysiological pathway involving vascular dysfunction, low-grade inflammation, and reduced mobility.

Conclusion: PWV represents a valuable, non-invasive marker for differentiating KOA severity and capturing broader inflammatory, metabolic, and functional impairment in postmenopausal women—without exposing patients to additional radiation.

ID 30 - Impact of a two-month community hospital rotation on PGY doctors' competencies in palliative care in Taiwan

Dagyeong LEE

Department Of Family Medicine, Hallym University Dongtan Sacred Heart Hospital, Hwaseong, Corée (République de)

Context: Low skeletal muscle mass is an established risk factor for adverse health outcomes, but its prognostic relevance in cancer remains insufficiently studied.

Objectives: We investigated the independent and combined effects of low muscle mass (LMM) and obesity on all-cause, cancer-specific, cardiovascular, and respiratory mortality in cancer patients.

Methods: This population-based cohort study included 635,867 cancer patients from the Cancer Public Library Database. LMM was defined as the lowest quartile on the appendicular skeletal muscle mass index (ASMI), estimated using a validated prediction equation. Obesity and abdominal obesity were defined as body mass index ≥25 kg/m² and waist circumference ≥90 cm in males and ≥85 cm in females, respectively. Patients were classified into four groups based on muscle mass and obesity status: normal muscle mass (NMM) without obesity, LMM without obesity, NMM with obesity, and LMM with obesity. Adjusted hazard ratios (HRs) and 95% confidence intervals (CIs) for mortality during follow up were calculated using Cox proportional hazards models.

Results: Compared with individuals in the highest ASMI quartile, those in the lowest quartile had significantly higher risks of all-cause (HR 1.25, 95% CI 1.23–1.27), cancer-specific (HR 1.21, 95% CI 1.19–1.23), cardiovascular (HR 1.49, 95% CI 1.36–1.64), and respiratory mortality (HR 2.26, 95% CI 1.99–2.56) during follow up. The association between LMM and higher mortality during follow up was more pronounced in early-stage cancer and older patients. Conversely, obesity alone was associated with lower mortality during follow up across outcomes: all-cause (HR 0.89, 95% CI 0.89–0.90), cancer-specific (HR 0.91, 95% CI 0.90-0.92), cardiovascular (HR 0.82, 95% CI 0.77–0.88), and respiratory mortality (HR 0.64, 95% CI 0.59–0.70).

Discussion: LMM was independently associated with increased mortality during follow up in cancer patients, regardless of obesity status. The adverse effect was amplified in those with sarcopenic obesity, but obesity alone showed a modest inverse association.

Conclusion: These findings highlight the clinical relevance of evaluating muscle mass and body composition in cancer prognosis.

ID 1337 - Primary care-led home palliative sedation for refractory seizure in a previously independent 94-year-old woman

Fakhrunnisa AKBAR

The Indus Hospital Karachi, Karachi, Pakistan

Context: In pregnancy, the practice of ingesting non-food items such as dirt, chalk and clay is referred to as pica, and it is a serious health risk both to the mother and the child. This behavior is usually seen in pregnant women and is associated with several complications, such as nutrition deficiency, anemia, and pregnancy-associated problems like preterm labor and low birth weight.

Objectives: To describe the extent of pica practices among pregnant women and its impact on maternal outcomes including anemia, preterm labor, and neonatal outcome including birth weight and Apgar scores.

Methods: This cross-sectional study was carried out at Indus Hospital and Health Network Karachi, Pakistan from January 2023 to June 2023. Self-administered questionnaires and hospital records of 300 pregnant women were used to obtain data. As screening criteria, the inclusion and exclusion criteria were defined, and the variables based on which the research would be conducted were identified.

Results: This study had a pica prevalence of 50%. Pica-practicing women had significantly low hemoglobin levels, high degrees of preterm labor, their neonates had low birth weight and low Apgar scores.

Discussion: This study emphasizes the significant negative impact of pica behaviors on the health of both mothers and newborns. The high prevalence of pica among pregnant women at Indus Hospital and Health Network Karachi, Pakistan, along with limited awareness about its risks, contributes to complications such as iron deficiency anemia, preterm labor, low birth weight, and low Apgar scores. These findings emphasize the importance of increased awareness and intervention. Healthcare professionals should regularly assess for pica during prenatal check-ups and provide pregnant women with information about the potential dangers associated with the condition while emphasizing the importance of a balanced diet. Due to the lack of comprehensive understanding regarding pica and its potential long-term consequences on both maternal and neonatal health, additional research is

necessary to gain insights into its root causes and establish effective preventive measures.

Conclusion: Pica behavior has been found to have negative consequences that affect the health of both the mother and the infant. Therefore, encouraging activities and additional testing during antenatal Care appointments are needed.

ID 39 - Association between Long-term Exposure to Air Pollutants and Thyroid Function

Amy MANTEN, Indra MELESSEN, Jelle HIMMELREICH, Eric MOLL VAN CHARANTE, Ralf HARSKAMP

Amsterdam Umc, Amsterdam, Pays-Bas

Context: Current telephone triage of chest pain in Dutch out-of-hours primary care (OOH-PC) is guided by protocols from the Netherlands Triage Standard (NTS), and has limited diagnostic accuracy. Clinical decision rules such as the Marburg Heart Score and INTERCHEST score may improve triage by providing better diagnostic discrimination than current NTS protocols.

Objectives: We evaluated the diagnostic accuracy of the MHS and INTERCHEST score for ACS or other major events in patients with chest pain contacting an OOH-PC facility, and compared their performance to the current triage protocol.

Methods: We conducted a prospective diagnostic accuracy study at a large regional OOH-PC facility in XXX, the Netherlands. Triage assistants asked study questions in addition to the NTS protocol to complete the MHS and INTERCHEST score. Performance was evaluated using C-statistics and diagnostic accuracy parameters regarding the occurrence of a major event (i.e. composite of all-cause mortality, and urgent cardiovascular and non-cardiovascular conditions) or acute coronary syndrome (ACS) within 6 weeks.

Results: A total of 1,254 eligible patients contacted the OOH-PC facility (median age 56.0 years, 57.9% female) between December 2022 and May 2023. Additional study questions were completed and informed consent obtained in 280 (22.3%) patients. Among these patients, a major event occurred in 36 (12.9%), including 13 (4.6%) ACS. For predicting major events, the MHS and INTERCHEST score showed C-statistics of 0.67 (95%-CI: 0.57-0.77) and 0.64 (95%-CI: 0.54-0.74), respectively, compared to 0.62 (95%-CI: 0.53-0.71) for the NTS protocol. At thresholds of ≥2 (MHS) and ≥1 (INTERCHEST), both scores showed higher point-estimates for specificity (MHS: 27.9%; INTERCHEST: 26.6%) compared to NTS (19.7%), but at the cost of lower sensitivity (MHS: 88.9%; INTERCHEST: 86.1%, vs NTS: 97.2%). None of the models showed significant discrimination for ACS.

Discussion: Our findings suggest that simple clinical decision rules may improve specificity, however, at the expense of reduced sensitivity, which limits their clinical utility for telephone triage of chest pain.

Conclusion: The MHS and INTERCHEST score have comparable, modest discriminative ability and diagnostic accuracy for major events compared to current protocols for telephone triage of acute chest pain in Dutch out-of-hours primary care.

ID 1098 - Association between air pollution and depression screening in XXX adults

Tânia GOMES, Ana Cremilda DURÃES, Tahydi VALLE

Usf São Vítor-Uls Braga, Braga, Portugal

Context: Chronic diarrhea is a frequent clinical problem, and determining its etiology can be challenging. While infectious and autoimmune causes are often explored, drug-induced enteropathies remain underrecognized despite their clinical relevance. Olmesartan, a widely used angiotensin II receptor blocker, has been increasingly associated with a sprue-like enteropathy that mimics celiac disease.

Methods: A 62-year-old man with hypertension, treated with amlodipine/olmesartan (5 mg/20 mg) for five years, presented to primary care with a six-month history of non-bloody, mucus-containing diarrhea and unintentional weight loss, without anorexia. Colonoscopy revealed intraepithelial lymphocytosis consistent with lymphocytic colitis, suggesting drug-induced lesions, celiac disease, or resolving acute colitis. Laboratory evaluation, including celiac antibodies and stool cultures, was negative. The patient was referred to Internal Medicine, where olmesartan was discontinued and further tests were performed. Three weeks after withdrawal, bowel habits normalized and weight gain was observed. Four months later, he remained asymptomatic, confirming olmesartan-induced enteropathy. Strengths of this case include thorough

diagnostic evaluation and complete clinical recovery after medication withdrawal; limitations include lack of histological follow-up.

Originality: This case adds to the growing recognition of olmesartan-induced enteropathy and reinforces the importance of considering drug-related causes in chronic diarrhea. Although similar cases have been described, awareness remains limited in clinical practice, leading to diagnostic delays. The present report contributes by emphasizing the reversible nature of the condition and the need for systematic medication review before extensive investigations.

Lessons learned and future implications: Clinicians should maintain a high index of suspicion for medication-related enteropathies in patients with unexplained chronic diarrhea. Early discontinuation of the offending drug can prevent unnecessary procedures and improve patient outcomes. Education and clinical guidelines should highlight olmesartan as a potential cause.

Discussion: Olmesartan enteropathy often mimics celiac disease histologically, with intraepithelial lymphocytosis or villous atrophy, but patients have negative serologies and fail to respond to a gluten-free diet. Other drugs, such as azathioprine, mycophenolate, methotrexate, neomycin, and colchicine, can cause similar lesions.

Conclusion: This case underscores the importance of considering olmesartan-induced enteropathy in patients with chronic diarrhea. Recognizing and discontinuing the causative drug leads to full recovery, highlighting the need for greater awareness of this reversible yet underdiagnosed condition.

(1) Faculté De Médecine De Montpellier-Nîmes, Vergèze, France
(2) Centre Hospitalo-Universitaire De Nîmes, Nîmes, France
(3) Faculté De Médecine De Montpellier-Nîmes, Bezouces, France

Context: In France, the prevalence of chronic diseases continues to rise, and physical inactivity is a major risk factor contributing to this trend. Physical activity, as a non-pharmacological intervention, is recognized for its ability to prevent and treat many chronic conditions. However, despite recommendations from the public authorities, written prescriptions for physical activity remain rare.

Objectives: We aimed to study whether the knowledge of a nearby Adapted Physical Activity (APA) facility promotes written prescriptions by general practitioners (GP) in the Eastern Occitanie region.

Methods: A cross-sectional survey was distributed via email to all GPs in Eastern Occitanie, using the mailing lists of the Conseil Départemental de l'Ordre des Médecins. The rate of written APA prescriptions over the previous 12 months was compared between physicians aware of an APA facility in their practice area and those who were not, using Chi-square tests and multivariate analysis. We used the https://occitanie-sport-sante.fr/ website to identify the presence of an APA facility in the GP's practice area.

Results: Of the 167 GPs who responded, 118 were included in the analysis. GPs aware of an APA facility in their practice area prescribed APA in writing seven times more frequently than those who were not. Eighty percent of respondents had an APA facility located within 5 km of their practice. No significant difference was found in the geographic distribution of APA facilities between prescribers and non-prescribers. In 18% of cases, no APA facility was listed within the practice area of GPs who reported being aware of such a facility in their territory.

Discussion: A lack of awareness of nearby APA facilities hinders the written prescription of physical activity by GPs. Two main limitations should be noted: the low response rate (5%), likely related to the email-based distribution method, and the presence of numerous unregistered APA facilities, as highlighted by our findings.

Conclusion: The results suggest that efforts should be made to improve the visibility of APA facilities among GPs, which could facilitate broader prescription of this non-drug therapy.

ID 151 - Pica Practices in Pregnant Women and Their Impact on Maternal and Neonatal Outcomes

Maram MEJRI

Department Of Emergency Medecine, Mahmoud Yacoub Center For Urgent Medical Assistance, Tunis, Tunis, Tunisie

Context: Acute alpha-chloralose intoxication remains a frequent cause of attempted suicide. Its main manifestations are neurological, ranging from mild symptoms such as tremors and mydriasis to severe conditions such as coma requiring mechanical ventilation.

Objectives: This study aimed to describe the epidemiological characteristics and clinical findings of patients consulting our emergency department (ED) for acute alpha-chloralose intoxication.

Methods: We conducted a retrospective, descriptive study in the ED of the Mahmoud Yacoub Center for Emergency Medical Assistance in Tunis over a period of 2 years (January 2023–December 2024). Data were analyzed from the records of patients consulting our ED for acute voluntary or accidental alpha-chloralose intoxication. The following variables were collected: demographic data, initial symptoms, physical examination findings, and management.

Results: A total of 50 patients were included, with a median age of 29.2 ± 9.27 years and a female predominance (70%). The majority of cases were intentional ingestions (95.9%), and only 4.1% were accidental. Twenty-two percent of the patients had a psychiatric history. Common symptoms included tremors (38%) and altered consciousness (33.3%). Notably, no cases of agitation or seizures were reported in our study. The median presumed ingested dose was 3g [3-5.5]. and the median delay to consultation was 2 hours [1-3]. Physical examination mainly revealed pupillary abnormalities, with mydriasis in 20% of cases and miosis in 8%. The median Glasgow Coma Scale score was 15 [8-15]. No abnormalities were noted on the rest of the examination, with a median heart rate of 92 beats per minute ± 17.5, SpO2 of 97%, systolic blood pressure of 123 ± 18.3 mmHg, diastolic blood pressure of 75.4 ± 11.8 mmHg, and a temperature of 37°C ± 0.4°C. Severe cases requiring intubation occurred in 44% of patients, who were subsequently admitted to the ICU. Twenty-six percent were transferred to the psychiatric ED. Discharge without transfer occurred in 24% of cases.

Conclusion: Alpha-chloralose intoxication was mainly voluntary and most frequently observed in young females. About half of the cases were severe, requiring mechanical ventilation.

ID 961 - Supporting Mothers Returning to Clinical Practice: A Practice-Based Reflection on NHS-Wide Experiences and Their Implications for General Practice

Ema DEJHALLA [1] , Tina ZAVIDIĆ [2]

(1) Medical Centre For Occupational Health Rijeka-Family Medicine Office, Rijeka, Croatie
(2) Istrian Health Centres, Lupoglav, Croatie

Context: Colonoscopy is a common procedure often coordinated through general practice and requires bowel preparation for adequate visualization. Although generally safe, bowel-cleansing regimens can occasionally cause serious electrolyte disturbances, particularly in elderly patients or those on diuretics. Awareness of these risks in primary care is essential for prevention and patient safety.

Methods: A 78-year-old woman developed severe symptomatic hyponatremia with a generalized tonic–clonic seizure after standard bowel preparation for colonoscopy. She consumed about four liters of water following a sodium picosulfate–based cleansing solution. On admission, her serum sodium was 117 mmol/L, confirming severe hypotonic hyponatremia. Other renal, hepatic, and endocrine causes were excluded. The episode was attributed to acute dilutional hyponatremia caused by excessive water intake, low solute load, bowel preparation, and chronic indapamide use. Careful correction with hypertonic saline led to full neurological recovery, and no further seizures occurred.

Originality: Although hyponatremia is an uncommon complication of bowel preparation, this case highlights the key role of general practitioners in identifying risk factors before colonoscopy. It shows how low solute intake, excessive water ingestion, and thiazide-like diuretic therapy can combine to cause acute hyponatremia. Even sodium picosulfate–based regimens, considered safe, may induce life-threatening electrolyte disturbances. The case adds to limited primary care literature by emphasizing medication review and individualized risk assessment.

Lessons learned and future implications: In general practice, thorough pre-procedure assessment in elderly or high-risk patients is essential. Physicians should provide clear fluid-intake advice, consider checking electrolytes, and temporarily stop diuretics when appropriate. Using lower-volume or isotonic regimens and improving communication between primary and specialist care can enhance safety.

Discussion: Bowel preparation–related hyponatremia is multifactorial, involving excess water intake, antidiuretic hormone activation, and drug effects. In family medicine, proactive medication review and patient education are vital to prevention.

Conclusion: Severe hyponatremia after bowel preparation, though rare, can cause seizures and neurological symptoms. Recognizing risk factors and providing tailored advice in general practice are key to safe colonoscopy preparation in elderly and comorbid patients.

Context: Sarcoidosis is a rare multisystem granulomatous disorder that often presents with non-specific symptoms, making diagnosis in primary care challenging. Early identification can prevent progression to pulmonary or systemic involvement. This reflection describes a diagnostic journey initiated in general practice that led to the confirmation of sarcoidosis through coordinated multidisciplinary collaboration.

Methods: A 32-year-old female presented with fatigue, arthralgia, and intermittent dry cough. Initial blood tests showed mild hypercalcaemia and raised ACE levels. Chest X-ray ordered by her GP revealed bilateral hilar shadowing. The GP referred her to respiratory medicine, where HRCT demonstrated perilymphatic nodularity consistent with sarcoidosis. Subsequent biopsy confirmed non-caseating granulomas. Throughout the process, the general practitioner coordinated communications between respiratory, rheumatology, and ophthalmology services, provided patient education, and monitored treatment response in the community.

Originality: This reflection highlights the pivotal role of the general practitioner in recognizing early, non-specific features of a systemic disease and ensuring timely investigation and referral. It demonstrates how continuity, accessible diagnostics, and holistic patient-centred care within primary care can expedite specialist evaluation and improve patient outcomes.

Lessons learned and future implications: Key lessons include maintaining vigilance for multisystem presentations, using structured baseline investigations (calcium, ACE, chest X-ray) in unexplained fatigue or arthralgia, and maintaining close communication with tertiary teams. The case reinforces the educational value of reflection in enhancing diagnostic reasoning and inter-service collaboration. Future implications include developing practice templates for unexplained inflammatory presentations and promoting GP-led follow-up protocols for stable sarcoidosis.

Discussion: Early recognition in general practice can significantly shorten the diagnostic delay in sarcoidosis, preventing unnecessary morbidity. This case underscores the importance of reflective practice, multidisciplinary teamwork, and continuity of care as core elements of high-quality family medicine.

Conclusion: Primary care physicians play a crucial role in the early detection and ongoing management of sarcoidosis. Structured reflection on such cases strengthens diagnostic acumen, fosters collaboration, and exemplifies the holistic ethos of general practice.

(2) Lille University, Lille, France

Context: Blood pressure measurement for the purpose of hypertension (HTN) screening is a routine procedure in family medicine practice.

Objectives: The objective of this study was to determine the appropriate frequency for hypertension screening in adults.

Methods: A systematic review of the literature was conducted in accordance with PRISMA guidelines. The databases PubMed, Embase, Cochrane CENTRAL, and LiSSa were searched in April 2024 using standardized search equations. The keywords were “hypertension” and “screening”. The terms “child”, “adolescent”, and “pulmonary hypertension” were used as exclusion criteria. The selection process was summarized in a flow diagram, and included studies were presented in tables. An update of the data was performed in July 2025.

Results: Four publications were included from the database search: two primary research articles and two guideline papers. An additional six guideline articles were included to supplement the data. The two primary research articles consisted of: - a cohort study assessing blood pressure variability over time to determine the appropriate screening frequency for hypertension; - a case-control study comparing the sensitivity and specificity of blood pressure measurement at each consultation versus annual measurement for hypertension diagnosis.

Discussion: There is limited primary research addressing the specific question of the appropriate frequency for hypertension screening. No study evaluating the impact of different screening frequencies on the incidence of hypertension-related complications was identified. These findings are consistent with a previous Cochrane Library review, which aimed to assess the effectiveness of various hypertension screening strategies in reducing hypertension-related morbidity and mortality, but found no eligible studies.

Conclusion: Current evidence suggests that: - screening for hypertension more than once a year has no proven benefit; - individuals at higher risk of complications (patients with cardiovascular risk factors, those of sub-Saharan African origin, or those with systolic BP ≥130 mmHg or diastolic BP ≥85 mmHg) should undergo annual screening; - individuals with normal blood pressure and no cardiovascular risk factors may be screened every 3 to 5 years. A prospective study comparing the incidence of hypertension-related complications among groups screened at different intervals would substantially strengthen the existing evidence base.

ID 438 - Perceptions of Community-Integrated Care and Determinants of Home-Visit Participation among Primary Care Physicians in Seoul: A Cross-Sectional Study

Jinseung KIM

4department Of Family Medicine, Busan Paik Hospital, Inje University College Of Medicine, Busan, Corée (République de)

Context: Obesity and overweight are increasingly recognized as contributors to cerebrovascular disease, including cerebral small vessel disease (SVD). Peak width of skeletonized mean diffusivity (PSMD), derived from diffusion tensor imaging (DTI), provides a sensitive and automated marker of microstructural white matter (WM) damage associated with SVD. However, the relationship between body mass index (BMI) and PSMD in neurologically healthy individuals remains unclear.

Objectives: To investigate whether people with overweight or obesity exhibit higher PSMD values—indicating greater SVD burden—compared with those of normal weight, using the World Health Organization (WHO) Asia-Pacific BMI classification.

Methods: We retrospectively analyzed data from 62 neurologically and medically healthy adults who underwent brain MRI with DTI. Participants were categorized as normal weight, overweight, or obese according to the WHO Asia-Pacific criteria. PSMD values were computed using a standardized automated pipeline based on tract-based spatial statistics. Group comparisons were performed using the Mann–Whitney U test. Associations between BMI and PSMD were examined using Spearman’s rank correlation and age-adjusted residual analyses.

Results: BMI was positively correlated with PSMD ($\rho = 0.42$, $p = 0.0007$), and the relationship remained significant after adjusting for age ($\rho = 0.38$, $p = 0.0021$). Participants with overweight (BMI ≥ 23.0 and < 25.0 kg/m²) showed significantly higher PSMD than those with normal weight ($2.24 \pm 0.22 \times 10^{-4}$ mm²/s vs $2.08 \pm 0.24 \times 10^{-4}$ mm²/s; $p = 0.0032$). When individuals with overweight and obesity were combined, this group also demonstrated elevated PSMD both before and after age adjustment ($p < 0.01$).

Discussion: These findings demonstrate that elevated BMI is associated with microstructural WM injury consistent with SVD, even at BMI levels classified as overweight in Asian populations. This suggests neurovascular vulnerability may occur

earlier along the BMI spectrum than previously recognized.

Conclusion: Higher BMI—including within the overweight range—was significantly associated with increased PSMD, reflecting early cerebral microvascular damage. PSMD may serve as a sensitive neuroimaging biomarker for detecting obesity-related white matter changes, underscoring the importance of early lifestyle and weight management strategies to preserve brain health.

Context: Strengthening health information systems to monitor antimicrobial utilisation (AU) is a core WHO AMR intervention for primary care. Leveraging electronic health records via dashboards enables timely AU surveillance. Strengthening health information systems to monitor antimicrobial utilisation (AU) is a core WHO AMR intervention for primary care. Leveraging electronic health records via dashboards enables timely AU surveillance.

Objectives: We describe the design and development of an AU dashboard to support an antimicrobial stewardship programme (ASP) across seven XXX in XXX for internal monitoring and external reporting.

Methods: The dashboard was co-designed with the ASP committee and XXX. Data came from the XXX AI platform integrating Epic electronic medical records. A daily 3:30 AM extract captured all encounters with prescribed antibiotics over a rolling 15-day window. Using Spotfire and Python, we implemented an ETL pipeline to: extract antibiotic orders; join medication tables to derive prescriber role, drug, route, and AWaRe class; map to natural units/strength and WHO defined daily dose (DDD); derive diagnoses/indications from same-day case notes via rule-based regex against a clinician-validated codebook; and join patient demographics (age, sex, race). AU metrics included DDD per 1,000 visits and counts by drug/class and prescriber. No predictive modelling was used; missing/erroneous source data were not imputed.

Results: The dashboard enabled near real-time AU monitoring (≤24-hour latency) with flexible filtering by clinic, prescriber, day of week, demographics, diagnosis/indication, and antimicrobial class/type, dose, duration, and frequency. Key views tracked the last 7 days: total medications, total prescriptions, and sum of DDD, alongside DDD per 1,000 visits. Operational performance improved markedly, reducing data preparation time from >6 hours to <10 minutes. The system supported external reporting to the AMR Coordinating Office and timely trend analyses to evaluate ASP interventions.

Discussion: Future work includes internal validation, external benchmarking, incorporation of cost analytics, and evaluation of subsequent ASP interventions.

Conclusion: This AU dashboard improved the accuracy, efficiency, and timeliness of AU reporting and visualization.

ID 2150 - Socioeconomic vulnerability and prenatal care provision in São Paulo State, Brazil: a spatiotemporal analysis

Shengying LING, Li WANG, Lina WU, Chao MENG

Renji Hospital, Shanghai Jiaotong University School Of Medicine, Shanghai, Chine

Context: The global population is experiencing increase in aging and rise in chronic diseases, among which falls represent a significant concern. Falls are the primary cause of injury-related mortality among older adults in XXX, leading to physical and psychological harm and economic burden. Existing research indicates that older adults with hypertension are at a heightened risk of falls, however, there is a paucity of data from communities in XXX. This study aims to fill this research gap.

Objectives: The study aims to describe the incidence of falls and identify associated risk factors among community-dwelling elderly patients with hypertension in XXX. The findings are intended to inform strategies for community management and intervention.

Methods: Study involved 703 hypertensive patients aged 65 and older from four communities in XXX. Fall was defined as having experienced at least one fall in the preceding three months. Sociodemographic characteristics, behavior and lifestyle factors, and medical history were collected. Univariate and logistic regression analyses were employed.

Results: 13.5% individuals reported fall within the preceding three months. It revealed significant associations between falls and factors such as age, marital status, duration of hypertension, smoking habits, polypharmacy, and comorbidities. Further analysis identified age (OR=2.970), extended duration of hypertension (OR=2.159), and the presence of comorbidities (OR=4.818) as significant independent risk factors.

Discussion: The observed fall incidence rate underscores the importance of this issue as a public health concern. The risk factors identified in this study are consistent with existing literature. Advanced age and the presence of comorbidities contribute to increased frailty, while a longer duration of hypertension may reflect greater physiological decline. Additionally, being unmarried or widowed, which may suggest reduced social support, lack of physical activity, and polypharmacy were also associated with a heightened risk of falls, highlighting the multifactorial nature of this issue. The role of community primary care is vital in the prevention of falls.

Conclusion: Falls among elderly hypertensive patients residing in the community are affected by a multitude of factors. It is imperative for community healthcare providers to formulate comprehensive and targeted preventive strategies that address these modifiable risks with the aim of reducing falls and enhancing overall well-being.

ID 911 - Screening examinations for adolescents aged 12-15 in a rural village

Youn HUH

Uijeongbu Eulji Medical Center, Gyeonggi-Do, Corée (République de)

Context: Metabolic dysfunction-associated steatotic liver disease (MASLD), previously referred to as non-alcoholic fatty liver disease (NAFLD), is the most common cause of chronic liver disease. MASLD is characterized by the presence of hepatic steatosis in conjunction with metabolic syndrome, without significant alcohol consumption. It is strongly associated with liver-related conditions such as cirrhosis, hepatic failure, and hepatocellular carcinoma, as well as with extrahepatic diseases. Depression is a depressed mood or loss of interest in activities and the most common psychologic disorder.6 It is estimated that approximately 300 million people worldwide affected depression.This disease is associated with the incident risk of CVDs, and metabolic diseases, such as obesity and diabetes mellitus.

Objectives: There were limited studies examing the associations between depression and metabolic dysfunction-associated steatotic liver disease (MASLD) among young adults. The present study investigated these associations in Korean young adults.

Methods: This is a cross-sectional study of Korean adults aged 19–44 years who participated in the Korea National Health and Nutritional Examination Survey in even-numbered years from 2014 to 2022. Depression was divided into two (no and depression) and four (normal, mild, moderate, and severe) groups using Patient Health Questionnaire-9 (PHQ-9). We analyzed odds ratios (ORs) and 95% confidence intervals (CIs) using multivariable logistic regression analysis to investigate the associations between depression and MASLD.

Results: Among 7831 participants, the proportions of MASLD were 23.8% in participants without depression and 33.9% in those with depression, respectively. Compared to young adults without depression, the OR for MASLD in those with depression was increased by 2.0 times (OR: 2.02) after adjusting confound factors. Compared to young adults with normal, the ORs for MASLD were at 1.96 for moderate and 2.45 for severe in young adults (p for trend <0.01).

Discussion: Young adults aged 19—44 years with depression were significantly associated with an increased risk of MASLD compared to these without depression. Moderate and severe depression were also associated with significantly associated with increased ORs of MASLD.

Conclusion: The present study demonstrated that more severe depression was associated with increased MASLD among young adults. It is

necessary to screen and manage for MASLD among young adults with depression.

Context: Unmet healthcare needs reflect critical gaps in accessing essential services, where individuals either do not receive needed care or face barriers to obtaining it. Despite XXX's universal health insurance coverage through the Health Insurance Fund (97% of population), significant health inequalities persist due to demographic, socioeconomic, and geographical factors. Understanding the relationship between sick leave and healthcare access is crucial for improving health system responsiveness and reducing health disparities.

Objectives: This study examines the relationship between sick leave duration and unmet healthcare needs among XXX's working-age population, identifying key barriers to healthcare access and population groups at highest risk.

Methods: A cross-sectional study analyzed data from 4,652 employed participants aged 18-65. The investigation focused on patterns of unmet healthcare needs and their association with sick leave duration. Chi-square tests examined associations between categorical variables, while binary logistic regression identified independent predictors of unmet healthcare needs, controlling for sociodemographic factors, health status, and social support.

Results: Overall, 12% of participants reported unmet healthcare needs in the previous year. Significantly higher rates (40.8%) were observed among those on long-term sick leave exceeding 30 days. Women demonstrated higher odds of unmet needs compared to men (OR=1.594, 95%CI: 1.283-1.980). Poor self-perceived health was the strongest predictor (OR=9.167, 95%CI: 5.427-15.483). Key barriers included extended waiting times, geographical distance, and financial constraints. Regional variations revealed fewer unmet needs in XXX compared to other regions. Weak social support networks correlated with increased unmet healthcare needs.

Discussion: Extended sick leave significantly impacts healthcare access, particularly affecting individuals with poor self-perceived health and women. The findings suggest that current healthcare system barriers disproportionately affect vulnerable populations. Regional disparities highlight the need for improved healthcare infrastructure outside the capital. The strong association between social support and healthcare access underscores the importance of comprehensive support systems.

Conclusion: This study identifies significant healthcare access disparities among XXX employees, particularly those on extended sick leave. Findings can inform targeted policy interventions to reduce waiting times, improve geographical accessibility, address financial barriers, and strengthen social support networks. Enhancing healthcare system responsiveness for vulnerable populations is essential for achieving health equity in XXX.

ID 1501 - Factors Influencing Jaundice Follow-up Rates in a Multi-Ethnic Asian Population: A Cross-Sectional Study

Sinead MURRAY

Irish College Of General Practice, Cork, Irlande

Context: Osteoporosis is a common, underdiagnosed condition associated with increased morbidity, mortality, and healthcare costs. Early identification of high-risk patients can reduce fracture incidence. Current guidelines recommend routine fracture risk assessment (FRAX) in women over 65, men over 75 and adults with osteoporosis risk factors including glucocorticoid use, family history, smoking, and diabetes. This practice reflection aims to measure compliance with evidence-based osteoporosis management in adults at risk of fracture and implement improvements in a single centre in Ireland.

Methods: A prospective chart review of 100 patients aged ≥50 attending in July 2025 was conducted. Data includes FRAX score documentation within 12 months, number of risk factors for osteoporosis, bone densomitry scan, charted diagnoses of osteopenia/osteoporosis, and initiation and monitoring of medications.

Originality: While most osteoporosis data in Ireland come from hospital studies, this audit focuses specifically on primary care, where at-risk patients are first seen. The integration of FRAX into the IT system and linkage with chronic disease reviews represents an innovative, actionable approach that can be scaled to other practices.

Lessons learned and future implications: This audit demonstrates a gap between international guidelines and actual practice. It underscores a need for a systemic screening process for osteoporosis. Re- audit in early 2026 will assess the effectiveness of implementing fracture assessment to routine health reviews, and incorporating frax as an auto-populated phrase on GP IT systems. This may provide a framework to be adapted to other practices.

Discussion: The results of first cycle audit demonstrate; no patient included had a documented fracture assessment. Of the 100 patients, 76 meet criteria for fracture assessment based on age and comorbidities. 24 patients had a previous DEXA; of those, 11 have osteoporosis, 12 osteopenia, and 1 had a normal scan. All patients on treatment for osteoporosis had up to date medications review.

Conclusion: While management and monitoring of diagnosed osteoporosis were appropriate, systematic case finding was lacking. Planned interventions including staff education and IT changes aim to embed fracture risk assessment into routine care. These measures are expected to improve identification and treatment of osteoporosis, ultimately reducing fracture rates and healthcare costs. Re-audit in 2026 will evaluate the impact of these changes.

ID 2053 - Beyond the Rash: Tinea Corporis Mimicking a Sexually Transmitted Infection in an Adolescent Male

Eugenie LEQUES

Universite Grenoble Alpes, Grenoble, France

Context: Gender-based violence (GBV) is a pervasive public health concern with enduring physical, psychological and social consequences. General practitioners (GPs) are often the first point of contact for victims-survivors and play a key role in identification, support and referral. One-stop centres such as the Maison des Femmes de XXX (MdFG) offer integrated, trauma-informed care models that may inform primary care practices.

Objectives: The primary objective was to describe the sociodemographic characteristics, health status, and violence exposure of patients attending the MdFG. Secondary objectives included exploratory analyses of associations between patient characteristics, violence exposure and patterns of care use.

Methods: This retrospective cross-sectional study included all adults (≥18 years) who received an initial in-person evaluation at the MdFG between November 2022 and April 2023 and did not opt out. Data were extracted from medical and administrative records up until April 2024.

Results: Data from 112 female participants were analysed. Most were of reproductive age, with one or more children, socioeconomically vulnerable, professionally inactive and single. Comorbidities were frequent: psychiatric (88.4%), somatic (78.6%), gynaecological (67%), and social (40.2%). Nearly all participants reported past GBV exposure (94.6%), with 48.2% disclosing ongoing violence, primarily in intimate or familial contexts. PTSD and moderate-to-severe depression affected 90% and 76%, respectively. Median follow-up was 336 days. Frequent interventions included GP consultations (69.6%), psychoeducation (59.8%) and physiotherapy (47.3%). Psychiatric follow-up and pharmacological treatment were limited.

Discussion: Participants presented with high levels of socioeconomic vulnerability, poly-victimisation and associated psychiatric and somatic comorbidities. Such results are in line with descriptive studies of one-stop centres across the world. Notably, depression and PTSD were highly prevalent while access to specialised psychiatric care remained limited.

Conclusion: Victims-survivors of GBV present with complex, overlapping health and social needs. This study highlights the essential role of GPs and the relevance of multidisciplinary, trauma-informed care models to enhance primary care responses to GBV.

Kiheon LEE [(1)] , Hyang Ki CHO [(2)], Sang Woo PARK [(3)], Sang Min PARK [(2)]

(1) Department Of Family Medicine, Seoul National University Bundang Hospital, Seongnam, Corée (République de)
(2) Department Of Family Medicine, Seoul National University Hospital, Seoul, Corée (République de)
(3) Department Of Biomedical Sciences, Seoul National University College Of Medicine, Seoul, Corée (République de)

Context: Both diabetes mellitus and smoking are major determinants of cardiovascular disease (CVD), and individuals with diabetes who continue smoking face substantially elevated cardiovascular risk. Heated tobacco products (HTPs) and electronic cigarettes (ECs) have recently emerged as alternatives to conventional combustible cigarettes (CCs), but evidence regarding their cardiovascular effects in diabetic populations remains limited.

Objectives: To assess whether switching from CCs to HTPs and/or ECs is associated with changes in CVD risk among adults with type 2 diabetes.

Methods: Using the Korean National Health Insurance Service database, we identified 267,928 individuals aged 40 years or older newly diagnosed with diabetes between 2010 and 2016. Smoking behaviors, including the use of CCs, HTPs, and ECs, were assessed by two standardized health screenings: the first within two years after diagnosis and the second in 2019–2020. Incident CVD, defined as hospitalization for ≥2 days or death due to coronary heart disease, myocardial infarction, or stroke (ICD-10 I20–I25, I60–I69), was identified through claims records. Multivariable Cox proportional hazards models estimated adjusted hazard ratios (aHRs) and 95% confidence intervals (CIs) for CVD outcomes according to smoking behavior transitions.

Results: Among 62,960 baseline CC smokers, those who switched to HTPs and/or ECs showed a modest, nonsignificant reduction in overall CVD risk (aHR = 0.78; 95% CI, 0.59–1.03), while dual users exhibited a similar trend (aHR = 0.86; 95% CI, 0.73–1.01) compared with continued CC smokers. Participants who quit all tobacco products had a significant risk reduction (aHR = 0.81; 95% CI, 0.74–0.88). When quitters were the reference, persistent CC use—but not HTP/EC use—was associated with higher CVD risk (aHR = 1.24; 95% CI, 1.13–1.36). Risk reduction was more pronounced for stroke (aHR = 0.56; 95% CI, 0.35–0.91).

Discussion: Switching from CCs to HTPs or ECs may partially mitigate CVD risk in adults with diabetes, particularly for stroke. However, these alternatives do not replicate the cardiovascular protection of complete cessation. Further longitudinal studies are needed to confirm durability and assess potential interactions with emerging antidiabetic therapies.

Conclusion: Switching from CCs to HTPs and/or ECs was linked to attenuated CVD risk compared with sustained CC use, but complete cessation remains the optimal recommendation.

Jinho PARK

Seoul National University Hospital, Seoul, Corée (République de)

Context: Despite the high burden of air pollutants in East Asia, the association between air pollutant exposures and thyroid function in the general population is inconclusive.

Objectives: This study aimed to investigate the association between annual exposure to air pollutants and thyroid function in Korean adults.

Methods: This study included a total of 16,193 participants without a prior diagnosis of thyroid disease. The annual average concentrations of five air pollutants, including particulate matter (PM2.5 and PM10), nitrogen dioxide (NO2), sulfur dioxide (SO2), and carbon monoxide (CO), were estimated using hourly measurements from nationwide monitoring stations. These measurements were linked to each participant's residential address and averaged over the 365 days preceding the date of thyroid function testing, including serum thyroid-stimulating hormone (TSH) and free thyroxine (FT4).

Results: Exposure to all air pollutants, including PM2.5, PM10, NO2, SO2, and CO, was positively associated with TSH levels and negatively associated with FT4 levels (all $p < 0.05$). The interquartile range increases in annual average concentrations of all air pollutants significantly increase the odds of being in the highest quartile of TSH and the lowest quartile of FT4 (all $p < 0.05$), respectively. The annual average

concentrations of air pollutants were significantly associated with low FT4 levels, whereas no significant associations were observed with elevated TSH levels (i.e., above the 95th percentile). In particular, among air pollutants, interquartile range increases in PM10 and SO2 concentration in the adjusted model demonstrated the highest odds ratio for the low FT4 group (odds ratio [OR] = 1.41; 95% confidence interval [CI] = 1.27–1.56), and this was higher in female (OR = 1.51; 95% CI = 1.31–1.74) than in male (OR = 1.44; 95% CI = 1.22–1.71).

Discussion: In this large population-based cohort study, we observed consistent associations between annual air pollutant exposure and thyroid hormone levels.

Conclusion: Annual exposure to air pollutants was positively associated with TSH and negatively associated with FT4 levels. Furthermore, higher annual air pollutant exposures were significantly associated with increased odds of low FT4 levels. The effect size was bigger in females than in males and further intervention study warranted.

ID 2084 - Coaching of interprofessional team practices to integrate physician assistants in XXX primary care within the project “Physician Assistants meet primary care” (PAAM)

Ya-Hui NIEN [(1)] , Liang Hao HSU [(2)], Ting-Fang CHIU [(1)]

(1) Department Of Education And Research, Taipei City Hospital, Taipei, Taïwan
(2) Division Of Occupational Medicine, Taipei, Taïwan

Context: In Taiwan, postgraduate year (PGY) training requires doctors to complete a two-month community hospital rotation, which includes exposure to long-term care and palliative medicine. Educational interventions during this period usually consist of lectures, ward observations, and home visits focusing on end-of-life care. However, evidence on the measurable learning outcomes of such programs in Taiwan remains limited.

Objectives: To evaluate the impact of a structured community-based curriculum, including palliative care teaching and home visits, on PGY doctors’ self-perceived knowledge and competencies in palliative care.

Methods: We conducted a pre–post study among PGY doctors in a community hospital rotation. A structured questionnaire covering seven domains of palliative care competencies (e.g., empathy, breaking bad news, symptom control) was administered at the beginning and the end of the two-month training. Scores were measured on a 10-point Likert scale. Paired t-tests were performed to assess differences between pre- and post-test scores.

Results: A total of 1,208 paired responses were analyzed. Significant improvements were observed across all seven domains: 1.Adequate training in palliative care: pre 5.42 vs. post 8.02 ($p < 0.001$) 2.Breaking bad news: pre 6.48 vs. post 8.18 ($p < 0.001$) 3.Guiding patients’ emotional responses: pre 6.09 vs. post 7.97 ($p < 0.001$) 4.Expressing empathy: pre 7.26 vs. post 8.50 ($p < 0.001$) 5.Discussing treatment options: pre 7.02 vs. post 8.32 ($p < 0.001$) 6.Managing end-of-life pain: pre 6.55 vs. post 8.18 ($p < 0.001$) 7.Guiding patients and families at end of life: pre 6.32 vs. post 8.04 ($p < 0.001$) All improvements were highly statistically significant ($p < 0.001$). The largest gain was in perceived adequacy of training (+2.6 points).

Discussion: The findings demonstrate that a structured community-based rotation substantially enhanced PGY doctors’ confidence and self-assessed competencies in palliative care. Compared with previous local studies in nursing and medical education, our data provide large-scale evidence in the PGY context.

Conclusion: A two-month community hospital rotation, including lectures and home visits on palliative care, significantly improved PGY doctors’ competencies across multiple domains. These results support strengthening palliative care training in postgraduate medical education and may inform curriculum development in Taiwan and similar settings.

ID 1409 - Mobile Application to Support Informal Caregivers of Patients with Alzheimer's Disease Context

Praveena MAHALINGAM

No, London, Royaume-Uni

Context: Cervical cancer remains a leading cause of morbidity and mortality among women globally. Women living with HIV (WLWH) are a sixfold increased risk compared to the general population, with an estimated 5% of all cervical cancer cases attributable to HIV World Health Organization. NICE

guidelines recommend more frequent (annual) screening within this group.

Objectives: Aim: to explore how primary care can enhance cervical screening uptake among this vulnerable group.

Methods: A retrospective audit was conducted using the database to identify HIV-positive women aged 25–64 registered between 2020 and 2023 (n=38). Data on coding accuracy, recall intervals, and reminder notifications were reviewed. Interventions included: Tailored Communication: Developing sensitive and appropriate materials to address diverse patient needs. Staff Training: Enhancing understanding of the challenges faced and the importance of personalised care. Patient Education: Providing information on the elevated cervical cancer risk and benefits of regular screening.

Results: Initial coding accuracy was 84%, but only 40% received annual screenings. Barriers included: - Systemic Factors: Inconsistent recall intervals and reminder notifications. - Interpersonal Factors: Healthcare providers reduced awareness about specific screening needs for WLWH. - Individual Factors: Patients' limited understanding of the importance of regular screening / non-engagement.

Discussion: A systematic review identified WLWH face barriers to cervical cancer screening, including lack of knowledge, fear and limited access to services. These challenges are compounded by healthcare system limitations and cultural factors. Addressing these barriers through targeted interventions is crucial to improving screening uptake and reducing disparities. Implementing integrated care models that include primary care services has been shown to enhance screening rates. To help mitigate these barriers, recommendations include: - Updating recall systems to clearly differentiate between patients requiring annual versus three-year screening intervals. - Providing training and clear guidance to healthcare professionals - implementing automatic alerts to patients' phone or addresses - Offering consultations to discuss reasons for non-engagement if possible.

Conclusion: This audit highlights the important role of primary care in promoting equity and humanism in healthcare. By addressing systemic, interpersonal, and individual barriers, providers can significantly improve cervical screening uptake among WLWH and contribute to the global effort to reduce cervical cancer as a public health problem.

Ruhi KHAN

King Khaled Eye Specialist Hospital, Riyadh, Arabie Saoudite

Context: This study examines the perceived need, barriers, and enablers of accessing mental health services among adult Saudi residents .

Objectives: To present the barriers, perceptions, and attitudes in accessing mental health services (MHS) among adult Saudi residents.

Methods: In this 2025 cross-sectional survey, a closed-ended questionnaire was used to understand awareness, attitudes, practices, perceived barriers, and enablers for seeking MHS. The determinants of the perceived need for MHS were compared with those of those who did not perceive a need for MHS.

Results: Our survey included 502 adults. The rate of availing and perceived need for MHS among surveyed adult participants was 17.7% (95% CI 14.2; 21.2) and 37.8% (95% CI 33.6; 42.1), respectively. The MHS need was significantly higher among Saudi participants compared to non-Saudi participants. [OR = 2.66, 95% CI 1.8-3.9, P <0.001]. Confidentiality (49%), lower cost (42.4%), and accessibility (43.8%) were leading enablers. The perceived challenges were accessibility and affordability, level of comfort, and effectiveness of MHS. The enablers (P = 0.84) and challenges (P = 0.53) were not significantly different among those with and without perceived need for MHS. The age group of 26 to 35 (P <0.001), Saudi participants (P <0.001), highly educated (P =0.002), and employed (P = 0.04) were associated with perceived need for MHS. Age group was the only significant predictor of MHS need.

Discussion: This study found a 20% gap between perceived need and use of mental health services (MHS) among Saudi adults, with confidentiality, access, and affordability seen as key enablers. Stigma, reputation, and employment concerns were major barriers. Saudis reported higher perceived need than non-Saudis, though barriers and enablers were similar across groups. Younger adults (25–35) were more likely to seek MHS. Findings highlight the need for culturally sensitive promotion, community and tele-MHS, and policies aligned with Vision 2030.

Conclusion: The gap between perceived need and MHS availing among adults is substantial. The '26 to 35' age group seems to be more vulnerable to MH issues needing interventions. The identified barriers and enablers could help in strengthening MHS for adults, mainly in the study area.

ID 409 - Sex-specific associations between muscle strength, resistance exercise, and health-related quality of life in older Korean adults

Meng-Che TSAI, Jansen Marcos CAMBIA, Chih-Ting LEE

National Cheng Kung University Hospital, Tainan, Taïwan

Context: Although regular physical activity is typically associated with enhanced well-being, the excessive and compulsive patterns of exercise characteristic of exercise addiction (EA), characterized by compulsive engagement in excessive physical activity, may paradoxically be associated with a decline in perceived well-being over time. A remarkable increase in the frequency and intensity of exercise across populations in different countries has been observed in recent years, but little is known in Asian contexts.

Objectives: We aimed to examine the prevalence of EA and its psychobehavioral correlates, combining the results of cross-sectional data from Taiwan, Malaysia, and India.

Methods: We assessed EA using the Exercise Addiction Inventory (EAI), with scores ≥24 indicating risk. General well-being was evaluated using the WHO-5 Well-Being Index and perceived healthiness. Psychological distress was assessed via the Hospital Anxiety and Depression Scale, while body image was assessed via the Muscle Dysmorphic Disorder Inventory (MDDI) and Drive for Leanness Scale (DLS). Eating behaviors were evaluated via the Eating Disorder Examination Questionnaire (EDEQ) and the Muscularity-Oriented Eating Test (MOET). Pearson correlation analyses and adjusted multivariate regression were performed to explore the relationship to EA. Pooled correlation and beta coefficients with 95% confidence intervals (CI) were reported.

Results: Among 2,680 participants, the pooled prevalence of EA was 11%. The highest risk was observed in India (15%), followed by Taiwan (10%) and Malaysia (9%). The adjusted pooled-bivariate model showed positive correlations between EAI and MDDI (estimate=0.39; 95% CI=0.22–0.54) and MOET (estimate=0.41; 95% CI=0.20–0.58). The pooled multivariate analysis identified positive associations with EAI for WHO-5, perceived healthiness, MDDI-functional impairment, DLS, EDEQ, and SCOFF, while MDDI-appearance intolerance and EDEQ-shape concern were negatively associated with EAI. At-risk EA was linked to well-being, psychological distress, body image concerns, and eating disorders.

Discussion: The main findings indicate that EA is not uncommon in these surveyed countries, with a varied prevalence of around 9-15%. Besides, we found a positive correlation between EA and psychological and behavioral factors such as perceived well-being, psychological distress, body image concerns, and eating disorders.

Conclusion: Considering the non-negligible prevalence and adverse impacts of EA, screening may aid early identification, especially in those with psychobehavioral issues.

(7) Flinders University, Adelaide,, Australie

Context: Chronic insomnia (more than three months duration) is a common and significant health problem which impacts negatively on mental and physical health, quality of life, and is associated with increased healthcare utilisation costs. Cognitive behavioural therapy for insomnia (CBTi) is an effective non-drug intervention. General practitioners commonly manage patients with insomnia but lack the time and referral options to either provide or refer patients for CBTi. These issues are compounded in rural and regional areas where mental health professionals such as psychologists are in short supply. In this context, use of sedative/hypnotic medications that can cause dependence and have adverse effects is common. Use of digital CBTi may be an option for providing low cost and accessible treatment but there is a need for evidence on effectiveness and whether clinician support and follow-up is needed.

Objectives: The study aims to compare two methods of delivering digital CBTi for chronic insomnia in primary care, with usual care (sleep hygiene advice).

Methods: The research plan has been co-designed with consumers and representatives of professional associations. In a three-arm cluster randomised controlled trial we compare the effectiveness and cost effectiveness of; 1) self-guided digital CBTi (access to an interactive digital CBTi program without GP support), 2) clinician-guided digital CBTi (digital CBTi + individualised onboarding and follow-up support from GPs), and 3) augmented usual care control (sleep hygiene advice, provided digitally).

Results: Patient outcomes assessed will include insomnia severity, depression, and use of sedative/hypnotic medication. A process evaluation will explore experience of the interventions from the perspectives of consumers and health professionals.

Discussion: The poster presentation will describe the intervention and study design. To date 33 GPs from 24 rural and regional general practices have agreed to take part in the study. The first block of 6 practices will be randomised in early 2026.

Conclusion: The study will explore whether digital CBTi is acceptable to people living in regional and rural locations, whether it is more effective than digital sleep hygiene advice, and the extent to which GP involvement increases uptake and effectiveness.

(1) Mayne Professor And Head, General Practice Clinical Unit, Medical School, The University Of Queensland, Brisbane, Australie
(2) Associate Professor, General Practice Clinical Unit, Medical School, The University Of Queensland, Brisbane, Australie
(3) Lecturer, Discipline Of Occupational Therapy, School Of Health Sciences And Social Work, Griffith University, Gold Coast, Australie
(4) Occupational Therapist, Occupational Therapy Driving Assessment & Rehabilitation Service, Princess Alexandra Hospital, Metro South Hospital And Health Service,, Brisbane, Australie

Context: Family doctors are often tasked with assessing fitness to drive in older drivers. As the population ages there are more older drivers. With age cognitive, motor and sensory function can decline potentially affecting fitness to drive. Assessing fitness to drive is important for protecting public safety. Yet some family doctors are not comfortable assessing fitness to

drive citing concern to maintain relationships and about the impact that driving cessation can have on an older person's wellbeing and independence, and poor access to on-road driving assessments. An objective measure could help to both inform clinical judgement and support maintaining relationships. We developed the 3-Domains screening toolkit that tests across the three functional domains essential for driving using tests that are feasible in general practice: sensory (Snellen visual acuity), motor (functional reach), and cognitive (road signs recognition test). The toolkit uses as online calculator to generate a predictive score that is the likelihood an older driver would pass a specialist occupational therapist driving assessment (%) based on

Objectives: To improve accuracy of the toolkit predictive equation.

Methods: Validation study in specialist Occupational Therapy Driving Assessment and Rehabilitation Service. Participants are older drivers referred by their family doctor for driving assessment including on-road driving test. Data includes demographics, visual acuity, functional reach, road signs recognition, Trail Making Test B, Rapid Pace Walk Test, Montreal Cognitive Assessment, Adelaide Driving Self-efficacy scale, previous incidents, and assessment outcome. Data analysis: Predictive validity will be displayed with absolute numbers and percentages. A receiver operating characteristic (ROC) curve will be produced, and the area under the ROC curve calculated. Driving assessment outcome will be dichotomized into pass/fail categories with "conditional" merged with "fail".

Results: Data collection is ongoing.

Discussion: Older driver medical assessment sometimes requires family doctors to balance their responsibility to the older driver against their responsibility to protect public safety.

Conclusion: The 3-Domains screening toolkit could be used to support older driver medical assessment, informing clinical judgement and supporting communication about the need for further on-road testing and to plan for eventual driving cessation.

(3) Prince Sultan Cardiac Center, Kfsh, Buraydah, Buraydah, Arabie Saoudite

Context: Left ventricular hypertrophy (LVH) is a common cardiovascular abnormality in type 2 diabetes mellitus (T2DM) patients. Its predictors within Middle Eastern populations are not well documented. This study aimed to determine the prevalence and independent predictors of LVH among patients with T2DM in Saudi Arabia.

Methods: A retrospective cross-sectional analysis of clinical experience was performed at a tertiary centre of diabetes in Saudi Arabia. Medical records of 625 adults with T2DM who underwent echocardiography were reviewed.

Originality: Demographic characteristics, comorbidities, diabetes duration, BMI, and glycemic control were collected. LVH prevalence was determined and comparisons between patients with and without LVH were performed. Multivariable logistic regression analysis for independent predictors.

Lessons learned and future implications: There were a mean age of 65.7 ± 11.4 years, of which 53.4 percent were male. Hypertension was present in 79% of participants and 78.2% had diabetes over 15 years. Most patients had uncontrolled HbA1c (77.6%). Obesity was the most prevalent BMI category (37.1%).

Discussion: LVH was detected in 23.4% of patients. It showed that male gender had significant relationship with LVH ($p = 0.002$). There were no significant differences for LVH vs non-LVH groups in age, hypertension, duration of diabetes, BMI and glycemic control. Overall

in our adjusted model, male gender continued to be the sole independent predictor of LVH (OR 1.71; 95% CI: 1.16–2.54; p = 0.007). No other independent variables predicted LVH.

Conclusion: In this Saudi retrospective cohort, LVH was prevalent in nearly one-quarter of patients with T2DM. Male gender was the only independent predictor of LVH, underscoring the need for targeted cardiovascular screening in this subgroup. These findings contribute region-specific evidence to the understanding of diabetic cardiac complications. Keywords Bariatric surgery, Hypoglycemia, machine learning

ID 1460- "Mirror Mirror on the Wall" Situs Inversus Totalis and Alpha Thalassemia in a 51 year old female: A Case Report

Öznur KÜBRA ODABAŞ

Ccupational Health Unit, Ankara Provincial Directorate Of Health, Ankara, Türkiye

Context: hyroid disorders are common in the general population; however, data on thyroid ultrasound findings obtained in primary care settings remain scarce. Ultrasound is increasingly used by primary care physicians, yet evidence regarding its role in evaluating thyroid structure alongside thyroid function in asymptomatic adults is limited.

Objectives: To evaluate thyroid ultrasound findings and thyroid function test results in a healthy adult population undergoing routine health screening in a primary care setting

Methods: This prospective observational study will include adult individuals aged 35–65 years undergoing periodic occupational health examinations with no thyroid-related symptoms at presentation. Thyroid ultrasound examinations will be performed by a primary care physician experienced in point-of-care ultrasound. Thyroid structure, including gland volume, echogenicity, and presence of nodules, will be recorded. Thyroid function tests (thyroid-stimulating hormone, free thyroxine, and free triiodothyronine) will be obtained concurrently. Demographic characteristics, medical history, current medications, and relevant lifestyle factors will be documented. Ultrasound findings identified in primary care will be referred to radiology for confirmation when clinically indicated. Associations between ultrasound findings and thyroid function parameters will be analyzed using descriptive statistical methods

Results: The study aims to describe the prevalence and characteristics of thyroid ultrasound findings in an asymptomatic adult population and their relationship with thyroid function test results in primary care. It is anticipated that structural thyroid abnormalities may be detected in individuals with normal laboratory findings.

Discussion: This study addresses an important evidence gap regarding thyroid ultrasound use in primary care. Evaluating thyroid structure alongside biochemical function may improve understanding of subclinical thyroid alterations in healthy adults.

Conclusion: Prospective assessment of thyroid ultrasound findings combined with thyroid function testing in primary care may provide valuable insights into thyroid health in asymptomatic populations and inform future screening strategies. Keywords (MeSH) : Primary Health Care; Thyroid Diseases; Ultrasonography; Screening

ID 1672- "Therapeutic Disobedience as an Act of Humanism

Marcos HERKENHOFF

Universidade Do Estado Do Rio De Janeiro, Rio De Janeiro, Brésil

Context: Health certification for sick leave is an important task in the daily work of physicians in the Primary Health Care setting in Brazil and worldwide.Health certification for sick leave is an important task in the daily work of physicians in the Primary Health Care setting in Brazil and worldwide.

Objectives: This work aims to discuss about he role family physicians play in the process of health certification for sick leave in the primary

health care setting in Brazil, by reviewing Brazilian and international publications and the regulations of the Federal Council of Medicine of Brazil (CFM) on this topic, in order to contribute to reflection on this issue in the Brazilian context and to propose ways to improve this task in practice.

Methods: This work employs a narrative literature review methodology conducted inside the Virtual Health Library platform, that includes multiple international databases such as LILACS, Medline, Arca, among others. The research used the meSH terms "Health Certificate" and "Sick leave", and selected international and brazilian publications inside the topic. Another part of the work included the regulation research inside the federal medical council portal, in order to find revelant norms on this topic issued by the brazilian concil. Finally, gray literature was included, such as governmental publications and the main brazilian Family Medicine textbooks.

Results: The reseach was able to select twelve articles, from wich only one brazilian paper, two from other latin american countries, and the other nine papers from european countries. The results demonstrate that the topic, understudied in Brazilian journals, is a relevant theme on the agenda of European countries and contextualizes the discussion within the scenario of welfare states.

Discussion: The study discusses the particularities of the role of the primary health care physician in Brazil, the technical component of disability assessment and the federal concil regulations.

Conclusion: It is concluded that the topic demands more studies in the Brazilian context, as it is a complex task of social relevance, whose improvement depends on intersectoral articulation, the articulation of the health care network, and a training process for professionals working in primary health care.

ID 971- "Trashcan junkie" to Faculty Chair: how to turn life-threatening negatives into career-affirming positives

Camila Cristina DE OLIVEIRA RODRIGUES, Márcio Cristiano DE MELO, Naila Albertina DE OLIVEIRA, Ivana Daniela CESAR, Zeliete LINHARES LEITE ZAMBON, Ana Cristina WIZIACK ZAGO

Faculdade São Leopoldo Mandic Araras, Araras, Brésil

Context: Primary Health Care (PHC) is central to medical education in Brazil, emphasizing early, supervised student engagement in community care. In private schools outside major cities, such as São Leopoldo Mandic de Araras, PHC integrates teaching, services, and community needs. Yet, how ambulatory production reflects activities for early training remains unclear.

Objectives: To identify and analyze ambulatory care procedures recorded in DATASUS that align with supervised practice of medical students in the first six semesters, considering the PHC curriculum (PHC I–VI), national guidelines, and SUS policies.

Methods: An ecological time-series study was conducted using secondary data from the Brazilian Outpatient Information System (SIA/SUS) for São Paulo between 2008 and 2024. Procedures compatible with supervised undergraduate practice were grouped into formative axes: health education activities; physical and integrative practices; educational home visits; basic nutritional assessment; collective oral health actions; workers' health education; patient reception; and total ambulatory production. Annual rates per 10,000 inhabitants were calculated using official population estimates. Joinpoint regression was applied to procedures with continuous data to estimate Annual Percent Change (APC) and identify trend inflection points.

Results: Selected procedures represented a broad spectrum of PHC activities aligned with early medical training. Home visits by mid-level professionals showed the highest rates, increasing from 8,670.4 per 10,000 inhabitants in 2008 to 10,422.2 in 2024, underscoring territorial and longitudinal care as a learning environment. Anthropometric assessment rose

until 2017 (3,956.4), declined during COVID-19, and partially recovered by 2024 (2,437.6). Group educational activities declined significantly (global APC = −11.1%; p<0.001), with sharp reduction between 2017 and 2020. Integrative practices and oral health actions became more frequent from the late 2010s onward.

Discussion: Ambulatory PHC production reflects service delivery and systemic changes. Educational and integrative activities proved more vulnerable to disruptions than home visits and anthropometric assessment, which may affect PHC-based curricula and student exposure to community-oriented practices.

Conclusion: Aligning medical education, SUS policies, and health information systems is essential to strengthen teaching–service integration and sustain community-oriented training. These findings highlight the need for resilient strategies to preserve formative activities during systemic challenges.

Faculty São Leopoldo Mandic, Araras, Brésil

Context: Cervical cancer screening through the Papanicolaou test is a core preventive action in primary health care and a central responsibility of Family and Community Medicine. In Brazil, screening performance reflects the territorial organisation of services, workforce availability, and continuity of care. Medical schools influence local health systems by training physicians, supporting service provision, and strengthening integration between education and primary care networks. However, few studies explore how the spatial distribution of medical schools relates to regional performance of preventive services, particularly cervical cancer screening.

Objectives: Marked territorial inequalities persist in cervical cancer screening coverage across São Paulo State. Understanding whether regions hosting medical schools demonstrate different screening patterns may inform workforce planning and health policy strategies to strengthen primary care systems.

Methods: We conducted an ecological spatiotemporal study including all 645 municipalities. Annual screening rates were calculated using secondary national data and aggregated by DRS. Medical schools were identified through administrative records and spatially linked to DRS. We used GIS to map spatial patterns and compared trends descriptively between DRS with and without medical schools.

Results: Screening rates displayed substantial spatial heterogeneity across São Paulo State between 2015 and 2024. DRS hosting medical schools comprised 29 regional units and concentrated mainly in urbanized and economically dynamic regions. These DRS consistently showed higher screening rates and greater temporal stability, including smaller declines during the COVID-19 pandemic. In contrast, DRS without medical schools exhibited wider variability and sharper reductions in screening activity. Regions sustaining higher screening intensity frequently overlapped with DRS that concentrate medical education institutions.

Discussion: The findings suggest that medical schools strengthen regional primary care capacity by improving workforce availability, supporting preventive actions, and fostering closer integration between education and service delivery. From a Family and Community Medicine perspective, medical education institutions appear to function as territorial anchors that enhance continuity of care and resilience of preventive services.

Conclusion: Integrating medical education planning with regional health policies may reduce territorial inequalities and strengthen cervical cancer screening performance within primary health care systems.

Infectious Diseases Department / Cdr Oran Hiv-Sti, Oran, Algérie

Context: Neurological or neuromeningeal manifestations are common during HIV infection.The diagnosis must be rapid because the patient's life may be at risk.

Methods: This is a retrospective descriptive study conducted at the HIV/AIDS/STI Reference Center in Oran, based on the medical records of patients followed for HIV infection between 2022 and 2025. HIV serology was confirmed in all patients. Analysis of encephalitic and paraclinical clinical signs was performed during the patients' hospitalization.

Originality: Demonstrate the frequency of neurological or neuromeningeal manifestations in HIV-infected patients in correlation with the degree of immunosuppression, to describe the epidemiological and clinical profile, and the evolution under treatment.

Lessons learned and future implications: We collected data from 160 patients living with HIV followed at the CDR, 44 of whom presented with neuro-meningeal manifestations, representing a prevalence of 27.5%. The age range was from 25 to 54 years. Clinical signs observed included: subacute headaches (72.73%); altered mental status (13.64%); seizures (11.36%); and balance disorders (9.1%). Diagnosed opportunistic infections included: cerebral toxoplasmosis (25%), tuberculous meningoencephalitis (20.45%), cryptococcal meningitis (22.73%), LEPM4 (9.1%), cerebral lymphoma (13.63%), and listeriosis (9.1%). Diagnostic methods relied on epidemiological and clinical findings, imaging (CT/MRI), lumbar puncture results, CSF PCR, CSF parasitology, and laboratory tests. More than half of the patients had a CD4 count <50/mm^3 and a high HIV viral load. Appropriate treatment for each neuro-meningeal manifestation was prescribed as soon as the diagnosis was made; antiretroviral therapy was initiated on average 20 days after the onset of opportunistic infection. The mortality rate was 27.27%.

Discussion: Neuro-meningeal involvement is a serious condition affecting people of all ages living with HIV. The clinical presentation varies depending on the type of opportunistic infection affecting the brain. These infections are common in cases of severe immunosuppression, and the prognosis is guarded despite antiretroviral therapy.

Conclusion: Neuromeningeal manifestations are a significant cause of morbidity and mortality during HIV infection. Early diagnosis followed by appropriate treatment of any opportunistic brain infection and effective antiretroviral therapy allows for better management of these manifestations.

Infectious Diseases Department, Oran University Hospital / Infectious Emergency Unit, Oran, Algérie

Context: Rabies-prone bites are a public health problem.The WHO: 59,000 people die from rabies each year worldwide.The human rabies, a deadly and endemic disease in our country, where 11 rabies deaths were reported in 2021.

Methods: A retrospective descriptive study of patient records from 2017 to 2025 presenting to the infectious disease emergency department following bites and/or scratches. Inclusion criteria: all patients presenting with one or more bites and/or scratches posing a risk of rabies. The management of all patients was in accordance with the ministerial guidelines concerning rabies risk.

Originality: Reporting cases of bites or scratches that pose a risk of rabies in patients

presenting to the infectious disease emergency department, and the importance of urgent care.

Lessons learned and future implications: The study collected 590 cases of bites and scratches that were recorded and reported, with a male predominance (79.34%) and a sex ratio of 3.84, primarily affecting young adults between 14 and 35 years old. 82% of the injuries were superficial. Among the biting animals, dogs were the most frequently implicated (74.25%), followed by cats (14.38%) and rats (11.37%). Stray animals were the most common victims (67%). The summer-autumn nighttime period (July to November) is the most conducive to animal aggression. The most frequently affected body parts among victims were: Hand (35%), Forearm (24%), Leg (19%), Face (9%), Neck (6%), Foot (5%), and other (2%). Diagnosed in the infectious disease emergency department, treatment was rapid, consisting of first aid and antibiotics. 92% received serovaccination, 8% received vaccination alone, and 90% received tetanus prophylaxis. Surgery was performed on 14 patients. Monitoring of the vaccination process was maintained.

Discussion: Compared to a study conducted in Africa (Abidjan, Ivory Coast, 2011): The exposed victims are predominantly male (79.34%) / Study: 57.40%. The affected age group varies, as in the African study. Dogs are the most frequently implicated animal (75.35%) / Study: (92.1%). Unvaccinated animals (89.85%) / Study: 87.2%. Post-exposure prophylaxis received by 100% of patients / Study: 50%

Conclusion: Despite the efforts made by the authorities in providing care, animal bites and scratches have become a very frequent reason for emergency room visits.

ID 1579- : Stigma and Social Vulnerability as Barriers to Integrated Care: The Importance of Family Medicine in the Context of Chemical Dependency

Rui Diogo RODRIGUES, Alice AVANZO, Beatriz MACHADO, Joana RAMINHOS, Ana PÓVOA, Natacha MURINELLO, Diogo TAVARES, Marlene CALISTO

Usf Carcavelos, Uls Lisboa Ocidental, Cascais, Portugal

Context: Chronic information dispersion regarding healthcare resources and community partnerships is a major barrier to efficiency in Primary Care. Fragmented data across institutional emails, static lists, and outdated websites hinders timely patient guidance and imposes a heavy administrative burden on healthcare teams.

Methods: Over a three-month period, a systematic mapping of resources was conducted through a review of institutional communications and direct engagement with local authorities, community associations, and pharmacies. Data were structured into an analytical matrix including service categories, eligibility criteria, referral protocols, costs, and locations. This repository was integrated into a natural language interface (LLM), allowing doctors, nurses, and administrative staff to query the database using plain language. The system provides instantaneous, structured answers to practical queries, such as: "List all psychology consultations available in the area", "Where can a patient measure blood pressure locally and at what cost?", or "What are the eligibility criteria for low-cost dental care?". The interface simulates an interaction with an intelligent, locally-curated resource guide.

Originality: To develop and implement a dynamic consultation interface based on a Large Language Model (LLM) to centralise and streamline access to local community and healthcare resource data for a Primary Care multi-professional team.

Lessons learned and future implications: Organisational literacy is a cornerstone of integrated care. By reducing the latency between identifying a patient's need and locating the appropriate resource (e.g., psychology services, pharmaceutical care, or

social activities), this tool minimises clinical inertia and enhances the precision of professional recommendations at the point of care.

Discussion: The tool effectively mitigated information compartmentalisation within the unit. It is anticipated that democratising access to this knowledge will allow administrative staff to take a more active role in social and logistical navigation in the future. This task-shifting potential could significantly release clinical time for doctors and nurses, allowing them to focus on diagnostic complexity and direct disease management.

Conclusion: The implementation of this AI-driven decision-support interface strengthens the professional-patient relationship by ensuring faster, evidence-based responses. In the long term, the ease of navigating resources translates into a direct benefit for the patient, who receives more efficient access to the health and social support systems available in their community.

ID 2186- ''Liberty, Equity, Fraternity'' in Practice: A Gamified Workshop on Adaptive Leadership Styles in Primary Care

Bernadette LENARTOWICZ

None, Warsaw

Context: Selective serotonin reuptake inhibitors, such as paroxetine, are widely used for major depressive disorder and social anxiety disorder. Although generally safe, SSRI discontinuation or tapering can rarely precipitate a withdrawal syndrome that includes autonomic dysregulation, anxiety exacerbation, and, in susceptible individuals, significant hypertensive crises. Heavy alcohol consumption during tapering further amplifies risk through sympathetic activation, dehydration, and potential pharmacokinetic interactions. This case illustrates the intersection of psychiatric treatment, substance use, and acute hypertension in primary care.

Methods: A 43-year-old male with long-standing major depressive disorder and social anxiety disorder treated with paroxetine 10 mg daily presented during medication tapering with severe hypertension (200/100 mmHg) at a psychiatric clinic. Initial captopril 12.5 mg reduced blood pressure (BP) to 190/90 mmHg, but the patient refused emergency services. Later that day in family practice, BP was 190/90 mmHg with HR102/min and oxygen saturation 98%. No symptoms were reported; ECG showed sinus tachycardia without ischaemic changes. The patient disclosed consuming 750 ml of whiskey the previous night. Nitrendipine 20 mg lowered BP to 180/90 mmHg. Hospital referral was declined.

Originality: This case uniquely demonstrates a severe hypertensive crisis triggered by the combination of low-dose paroxetine tapering and acute heavy alcohol intake in an otherwise asymptomatic patient with psychiatric comorbidity and stage-one obesity. The rapid onset, absence of end-organ symptoms, and patient refusal of acute hospitalisation highlight challenges in managing acute cardiovascular complications during psychiatric medication adjustment in ambulatory settings.

Lessons learned and future implications: Early recognition of SSRI withdrawal and alcohol-related sympathetic surge enables prompt outpatient management with antihypertensive polytherapy and electrolyte support. Lifestyle intervention combined with nephroprotective multidrug regimens can achieve rapid BP normalisation without excessive HR reduction.

Discussion: Acute hypertension during SSRI tapering may be exacerbated by alcohol-induced catecholamine release and volume shifts. Fixed-dose combination antihypertensives with nephroprotective properties, alongside aggressive lifestyle modification, offer effective and tolerable control in motivated patients.

Conclusion: Initiation of triple antihypertensive therapy (hydrochlorothiazide/ARB/calcium channel antagonist), beta-blocker titration adjustment, electrolyte replacement, and strict DASH diet with alcohol abstinence rapidly normalised BP, reduced weight, and improved

cholesterol. This integrated approach successfully managed a potentially life-threatening hypertensive crisis in an outpatient psychiatric-primary care interface.

Rachid CHOUKRI

College National De Medecine Gerale Et De Famille, Rabat, Maroc

Context: On the verge of expanding its Universal Health Coverage (UHC), Morocco faces an urgent need to strengthen primary healthcare through a family medicine training program. With no family medicine departments in the nine national universities, the Master's program in Family and Community Health at the National School of Public Health in Rabat offers a promising interim solution, proven effective at the ten operational Family and Community Health Centers.

Objectives: Graduates of this Master's program offered by the National School of Public Health (ENSP) are trained to: - Assess health needs at the family and community level - Plan and implement preventive and health promotion initiatives - Coordinate care within a family medicine and primary care framework - Analyze health data and propose targeted solutions - Conduct applied research to improve healthcare services This program aligns with Morocco's National Health Strategy (Health Plan 2025) and aims to strengthen family medicine and primary care as the cornerstone of the health system, while developing specialized training tailored to population needs.

Methods: -Literature review and desk work - Interviews with training program coordinators - Visit to a community medicine center (in Casablanca)

Results: -The Master's program is comprehensive, combining theoretical courses with practical immersion in health centers and local hospitals. -Supporting the doctors and staff in charge of these health centers through around sixty training sessions enables them to perform their tasks with confidence and ease. - The evaluation report highlights the viability of the project and its potential for replication at other sites.

Discussion: Private sector general practitioners, aware of the existence of this Master's program, wish for it to be adapted to the conditions of practice in private clinics.

Conclusion: Strengthening primary healthcare in Morocco is a "must" to achieve Universal Health Coverage (CUS)

(1) Uppsala University - Uppsala (Sweden), Uppsala, Suède
(2) Region Uppsala, Uppsala, Suède
(3) Uppsala University, Uppsala, Suède

Context: Evidence from several European countries, including recent target trial emulation and qualitative work, shows that improving continuity, coordination, and patient experience can reduce avoidable hospital use and strengthen patients' sense of safety. Yet many primary care teams lack practical tools to translate this knowledge into everyday practice and system-level change.

Objectives: Describe key challenges and inequities in the care of older people with multimorbidity in their own context, linked to the themes of Liberty, Equality and Fraternity. Identify a small set of feasible process measures (e.g. continuity, follow-up, care planning) and outcome measures (e.g. perceived safety, avoidable hospital use) relevant to their primary care setting. Draft a simple, context-specific improvement plan for older people with multimorbidity, including roles for patients, primary care teams, and other sectors. Share and reflect on strategies for interprofessional and cross-sector collaboration (Fraternity) that respect patient

autonomy (Liberty) and promote fair access and outcomes (Equality).

Teaching method and workshop: Methods: Short presentations, small-group work, structured discussion, and real-world examples from participating countries. Proposed schedule (90 minutes): Brief presentation of key evidence on multimorbid older adults: continuity, avoidable hos

Expected outcomes: Have a clearer understanding of how the themes of Liberty, Equality, and Fraternity can be operationalized in everyday care for older people with multimorbidity. Gain concrete examples of process and outcome indicators (clinical, organizational, and

Conclusion: Caring for older people with multimorbidity is a shared European challenge that sits at the heart of family medicine. By systematically applying the principles of Liberty, Equality, and Fraternity, primary care teams can redesign local systems to improve continuity, perceived safety, and the appropriateness of hospital use. This interactive workshop will help participants translate evidence and policy into practical, measurable changes in their own contexts, and foster ongoing dialogue and collaboration across countries.

Antonio EGIDOS, Daniel GONZÁLEZ TOBIAS, Elke HERRANZ ALMIRALL, Laura CARRASCOSA

Cap Gòtic, Barcelona, Espagne

Context: Herpes simplex virus (HSV) and varicella zoster virus (VZV) are higly prevalent pathogens that establish lifelong latency and can reactivate, causing significant morbidity, especially in immunocompromised and older adults. Nevertheless, the differentiation of these two entities can be challenging specially when they present as atypical forms.

Methods: A 46-year-old male with medical history of aortic mechanical valve, hypertension and chronic alcoholic liver disease attends General Practitioner (GP) consultation for itchy skin lesions in the cervical region. After history taking and the explanation of the course of the symptoms, VZV is the suspected diagnoses. However, the lack of pain and non-metameric distribution of the lesions in the right cervical region, make a young GP doubt. Culture samples are taken and antiviral treatment is not prescribed due to several days evolution, with a symptomatic approach. Days after, with a positive result for HSV and after a literature revision, the case is diagnosed as atypical presentation of HSV, a rare but important form of HSV infection.

Originality: Dermatology is sometimes the big feared and forgetted subject for the young GP, due to its' difficulty and the lack of experience. A rare form of presentation of a common dermatological condition is an interesting way of addressing this topic.

Lessons learned and future implications: Most common and diseases that we are most used to see in our consultations can sometimes be the more challenging. Unusual presentations, strange responses to treatment or unkown facets of this disease can betray the confidence with whom we usually adress these topics. . .

Antonio EGIDOS, Daniel GONZÁLEZ TOBIAS, Elke HERRANZ ALMIRALL, Laura CARRASCOSA

Cap Gòtic, Barcelona, Espagne

Context: Contact lens use is a major risk factor for sight-threatening ocular pathology, particularly microbial keratitis, which can lead to permanent vision loss or require corneal transplantation if not promptly treated. The pathogenesis involves disruption of corneal barrier function, increased susceptibility to infection by bacteria (notably Pseudomonas aeruginosa), fungi, and Acanthamoeba, and induction of chronic inflammation and metabolic impairment in the corneal epithelium. The high prevalence of poor lens

hygiene and risky behaviors among wearers underscores the need for meticulous care and regular professional oversight to prevent these serious complications.

Methods: A 43-year-old male with personality disorder as only as only medical history attends to a urgent demand consultation at a General Practitioner Centre in Barcelona. The reason for consultation is red and painful eye. After brief history taking and ocular inspection, several severe and urgens pathologies are considered under the differential diagnosis (uveitis, foreign body, corneal erosion or ulcer, etc). The patient referred use of contact lenses but denied the use in the previous week. Once the ocular exam was performed, contact lenses in both eyes were found. After fluoresceine tinction of the painful eye, superficial pitting and unique corneal ulcer was diagnosed. The patient was referred to Oftalmology Emergency Care Centre for treatment.

Originality: Oftalmology is often an unknown and feared topic in General Practitioner consultation. Nevertheless, with some clear concepts and minimum clinical exploration and procedures, a strong presumption of diagnosis can be issued.

Lessons learned and future implications: A methodic history taking, physical examination and high level of suspicion, is critical in low-resources environments such as a General Practitioner consultation. Furthermore, when it comes to less known topics, a orderly way of working is critical. . .

Veronica MIRANDOLA, Giulia SAVASTANO

Asugi, Trieste, Italie

Context: Nowadays, General Practitioner (GP) have to face the progressive aging of the population. Due to that, GP have to deal with increasingly complex therapeutic decision-making in ultra-nonagenarian patients with advanced peripheral arterial disease (PAD). Extreme frailty and multiple comorbidities often lead to a conservative management approach. This study analyzes the effectiveness and sustainability of revascularization in this specific age group.

Objectives: The aim of the study was to consider the impact of minimal invasive surgery in nonagerian patients with PAD.

Methods: We have reviewed nonagenarian patients with PAD (Rutherford category 4-5-6) underwent to revascularization with minimally invasive approach between 2019 and 2024. Preoperative evaluation of cognitive impairment and Activities of Daily Living (ADL) were performed. The primary outcome were technical success of the procedure and 30-days, 6 month and one year mortality. The secondary outcomes were intra-hospital morbidity, limb savage and ADL manteinance.

Results: 48 patients were prospectively enrolled and retrospectively analyzed. The technical success was 97.7%. 30-days mortality was 9.3%. Kaplan-Maier analysis showed an overall 6 month survival of 70%, and 1 year survival rate of 55%. Medical complications were 12.5% (4 patients with acute kidney injury; 2 patients acute coronary syndrome). 1 patient required major amputation. 79% preserved or improved the ADL after hospitalization .

Discussion: During the previous years lower limb revascularizations in nonagerian patients with PAD was not considered due to its high peri-operative risk. Due to that, nonagerian patients usually underwent to major amputation. Mini- invasive techniques development allowes lower limb savege in selected nonagerian patients. The results of the study confirmed a relative low rate of 30-days mortality with an high technical success. Futhermore, results showed the maintenance of ADL and mental ability after hospitalization.

Conclusion: In order to avoid major amputation and preserve a good autonomy and quality of life, mini-invasive revascularization should be considered in nonagenarian patients with PAD.

Mesva, Univaq, L'aquila, Italie

Context: Cardiac amyloidosis is an underrecognized cause of heart failure, particularly in patients with preserved ejection fraction (HFpEF). Its clinical presentation is often subtle and overlaps with more common cardiovascular conditions, leading to delayed or missed diagnosis. Primary care physicians may play a key role in early identification through recognition of characteristic clinical and laboratory “red flags”.

Objectives: To evaluate the prevalence of clinical and laboratory features suggestive of cardiac amyloidosis in a population followed in general practice and to assess the occurrence of confirmed diagnoses within this setting.

Methods: A retrospective observational analysis was performed on 4,407 patients followed by general practitioners in L’Aquila and Avezzano (Italy) in May 2025. The presence of the following conditions was assessed: HFpEF, aortic stenosis, carpal tunnel syndrome, peripheral neuropathy, persistently elevated troponin levels, and ventricular hypertrophy.

Results: The mean age of the study population was 62.6 ± 8.4 years, and 54.9% were female. The most frequently observed conditions were left ventricular hypertrophy (4.15%), carpal tunnel syndrome (2.83%), persistently elevated troponin levels (2.06%), HFpEF (1.52%), peripheral neuropathy (0.42%), and aortic stenosis (0.03%). Two patients (0.03%) received a confirmed diagnosis of wild-type transthyretin cardiac amyloidosis.

Discussion: Although the prevalence of confirmed cardiac amyloidosis was low, multiple patients exhibited clinical features commonly associated with the disease. The coexistence of these findings in a primary care population highlights the potential for underdiagnosis and suggests that systematic evaluation of red flags may improve case detection outside specialized centers.

Conclusion: Despite being classified as a rare disease, cardiac amyloidosis can be encountered in general practice. Increased awareness and recognition of suggestive clinical and laboratory features by general

practitioners may facilitate earlier diagnosis and more timely referral, enabling access to disease-modifying therapies.

ID 63- "Medical, or Not Medical, That is the Question" A workshop to explore what it means for GP's to heal, care, and support.

Dimitrios VASILAKIS, Stavros SPANOUDIS, Christina ARCHONTAKI, Martha KARYDA, Ilias Viktor TSIRIGAS, Nikiforos TRIANTOULIS, Pantelitsa KOURI

Health Care Center Of Agia Varvara, Heraklion, Grèce

Context: Social isolation among older adults is a growing challenge in rural primary healthcare. Standard, time-limited consultations often fail to capture psychosocial needs, loss of dignity, and reduced social participation. Person-centered, community-based approaches are needed to address aging more holistically. Oral history offers a narrative-based tool grounded in active listening.

Methods: The intervention was conducted in Vasilies, a rural community of approximately 1,000 residents in the Heraklion region of Crete. Ten older adults participated voluntarily. Oral history was used as both a qualitative research method and a community-based intervention. Structured and semi-structured interviews were held in non-clinical settings, focusing on life trajectories, social roles, and experiences of aging. Narratives revealed psychosocial and social determinants of health rarely identified in routine medical practice. Insights informed locally relevant community responses.

Originality: This case integrates oral history into rural primary care as both an intervention and a diagnostic tool, positioning older adults as active contributors to community life.

Lessons learned and future implications: Oral history proved empowering and ethically meaningful. Future applications should include appropriate training, follow-up, and mixed-method evaluation.

Discussion: This experience demonstrates that oral history can bridge the gap between clinical care and community life, revealing dimensions of health that are otherwise overlooked. By aligning healthcare practice with narrative meaning-making, primary care can move toward a more holistic and dignified model of aging care. Additionally, the community benefits through the preservation of collective memory and intergenerational knowledge transfer.

Conclusion: Oral history is a feasible, complementary tool that supports a dignified, person-centered approach to aging and community health in rural primary care, while also enabling targeted community-level interventions that address social determinants of health and, consequently, contribute to improved population health.

Antonio EGIDOS, Daniel GONZÁLEZ TOBUAS, Elke HERRANZ ALMIRALL, Laura CARRASCOSA

Cap Gòtic, Barcelona, Espagne

Context: In a society with a growing concern on the autonomy of the patients – specially elderly patients – and in which the confidence and physician-patient relationship is being doubted due to artificial intelligence and tele-medicine, restoring this confidence and relationship is a major issue for general practitioners. Thus, standarized and conscious use of verbal consent before the medical care at a nurse home is a good strategy to respect patient autonomy, establish a confidance relationship and respect ethical principles in medical care.

Objectives: Assess the degree of well-being obtained and the gain of confidence in the general practitioner in nursing homes patients by implementing the regular use of verbal consent before the medical care.

Methods: An uncontrolled before-after study is performed with nursing homes' patients from

our neighborhood. Interested, mentally not impaired and physically capable patients are selected, and a satisfaction and well-being questionnaire is performed after the verbal consented medical care at the nursing home.

Results: This study is already ongoing, and the results will be available by the time of Wonca 2026 conference.

Discussion: Assessment of patients' well-being and patient autonomy enhancement is a poorly addressed topic in medical literature, although the vital importance of the issue. Thus we perform a study to asses the importance and impact of this topic.

Conclusion: This study is already ongoing, and the conclusions will be available by the time of Wonca 2026 conference.

ID 313- "Unprofessional feelings" – a qualitative study of general practitioner survivors' experiences, when working with people who use domestic and family violence

Maria Alyssa DULATRE, Girlie RELLERA

Southern Isabela Medical Center, Santiago City, Philippines

Context: Acute neuromuscular weakness in adolescents is uncommon but potentially life-threatening. Guillain-Barré syndrome (GBS), an immune-mediated neuropathy often following infection, requires early recognition and coordinated care. In primary care settings, family physicians are frequently the first point of contact, placing them in a critical position to identify red flags and initiate timely referral while addressing psychosocial impact.

Methods: This practice-based case report describes a 17-year-old female who presented with rapidly progressive, symmetrical ascending weakness following a recent upper respiratory tract infection. Initial assessment in a family medicine outpatient clinic included a comprehensive neurologic examination, family assessment, and counseling. Key findings were flaccid paralysis, absent deep tendon reflexes, preserved sensation, and evolving functional dependence. The patient was promptly referred for inpatient care, where diagnostic work-up confirmed Guillain-Barré syndrome and intravenous immunoglobulin therapy was initiated. Ongoing management involved rehabilitation, adolescent medicine support, and structured family meetings. Functional recovery and caregiver burden were monitored longitudinally.

Originality: While GBS is well described neurologically, this case emphasizes the family-centered role of the family physician in early detection, care coordination, counseling, and continuity beyond hospital discharge. Integrating clinical vigilance with family assessment tools and patient-centered counseling highlights an often underreported dimension of GBS management in adolescents.

Lessons learned and future implications: Early suspicion of GBS in primary care can significantly alter outcomes. Addressing emotional distress, family dynamics, and uncertainty alongside biomedical care reduced anxiety and improved engagement with rehabilitation. Family-centered counseling should be integrated early in acute neurologic illnesses.

Discussion: This case underscores the importance of recognizing ascending paralysis as a medical emergency and illustrates how family medicine bridges acute care, specialty referral, and long-term recovery. Adolescents face unique psychosocial vulnerabilities that warrant deliberate attention.

Conclusion: Family physicians play a pivotal role in the early recognition and holistic management of Guillain-Barré syndrome. Timely referral, coordinated multidisciplinary care, and sustained family engagement can preserve function, dignity, and hope during recovery. MeSH Keywords: Guillain-Barré Syndrome; Acute Flaccid Paralysis; Adolescent Health; Primary Health Care; Rehabilitation

Context: Family physicians educate their patients, peers, residents, students and other health professionals. Research reveals that teaching does not imply recipients have acquired the necessary knowledge. In order for family physicians to enhance the impact of their education, they need to be equipped with the knowledge and skills related to adult learning where facilitation methods are used instead of the standard techniques.

Objectives: Building on our extensive experience in both developed and developing countries, this workshop aims to equip the audience with the knowledge and skills needed to apply facilitation methods to foster adult learning.

Teaching method and workshop: Using facilitation techniques, we will take the participants on an adult learning journey to discover adult learning and its importance, understand the difference between facilitation and traditional techniques, devise learning outcomes rather than object

Expected outcomes: By the end of the workshop, the participants will be able to explain the concept of adult learning, differentiate between facilitation and traditional education, apply facilitation techniques to common scenarios in family practice.

Conclusion: Globalisation and access to technology have changed how we learn and acquire knowledge. Adapting to those new changes are essential for family physicians who are keen to make a difference through education.

ID 1978- A 12-week Randomized Double-Blind Clinical Trial, Evaluating the Effect of Lithospermum erythrorhizon (Gromwell) Root Extract on Skeletal Muscle Function in Adults over 50 Years of Age

Melike AKCAKAYA, Umut GOK

Izmir City Hospital, Izmir, Türkiye

Context: Cancer-related nausea and vomiting are among the most distressing symptoms in palliative-care patients, severely impairing quality of life and oral intake. In terminal gastric cancer, multifactorial mechanisms often render symptoms refractory. In patients with metoclopramide allergy, the limitation of standard antiemetic options further complicates symptom management.

Methods: A 40-year-old woman with asthma and signet-ring cell gastric carcinoma was admitted to a family physician–led palliative care unit because of severe vomiting and complete loss of oral intake. Her quality of life had deteriorated. She also had dyspnea and abdominal distension. Laboratory tests were hemoglobin 9.9 g/dL, creatinine 2.84 mg/dL, sodium 132 mmol/L, and CRP 28 mg/L. Imaging revealed pleural effusion and ascites. Pleural catheter placement and paracentesis were performed. Acute kidney injury was considered post-renal and resolved after drainage and supportive care. Despite granisetron, proton pump inhibitors, and antacid therapy, nausea and vomiting persisted. Metoclopramide could not be used because of allergy.

Originality: After renal function normalized and infection markers were closely monitored, a short course of methylprednisolone was started, and olanzapine was added. Although olanzapine is mainly known for anxiolytic and antipsychotic effects, it is effective in nausea and vomiting through dopaminergic, serotonergic, and histaminergic pathways. This combination resulted in rapid and complete resolution of vomiting. Oral intake was restored, and the patient was able to eat her favorite foods during the final period of her life.

Lessons learned and future implications: In terminal cancer patients with refractory nausea and vomiting, short-term corticosteroids

combined with olanzapine may be considered when infection parameters and organ function are carefully monitored. Olanzapine may also reduce cancer-related anxiety, providing dual benefit. Early control of ascites and pleural effusion improves antiemetic response.

Discussion: Previous studies report that olanzapine is effective in refractory nausea and vomiting in palliative and oncology settings. Corticosteroids have also been shown to enhance symptom control by reducing inflammation and visceral edema. The clinical response in this case is consistent with the existing literature.

Conclusion: In this terminal gastric cancer case, refractory nausea unresponsive to standard therapy was successfully controlled with olanzapine and short-course methylprednisolone. Individualized pharmacological treatment in palliative care supports comfort, dignity, and humanity at the end of life.

(5) Aldoar Family Health Unit, Porto, Portugal

Context: Lifestyle Medicine (LM) has emerged as a key response to the growing burden of non-communicable diseases and the need for prevention-focused, person-centred healthcare. Its emphasis on behavioural and environmental determinants of health aligns with the core principles of Family Medicine (FM). However, the role of LM within FM remains a contested issue. Questions persist as to whether LM should be considered an intrinsic component of FM practice, a formally recognised competency across medical specialties, or a transversal field linking clinical care, public health, and community action. Across Europe, variation in training structures, healthcare systems, and service delivery models reinforces the need for a shared strategic vision regarding LM integration in FM.

Objectives: • Critically reflect on the current and potential role of LM within FM. • Identify key perceptions, barriers, opportunities, and risks related to the integration of LM into routine FM practice. • Compare and appraise different models for positioning LM, including core discipline, accredited competency, and cross-sector approach. • Contribute to the development of preliminary recommendations to support professional training, service organisation, and policy development.

Teaching method and workshop: The workshop will adopt an interactive approach, combining brief expert input with facilitated small-group work and plenary discussion. A structured SWOT analysis will support reflection and peer exchange, while moderated debate will foster synthesis and

Expected outcomes: Participants will gain clearer insight into the positioning of LM within FM, increased awareness of implementation challenges and enablers, and a shared understanding of future strategic options. The workshop will produce initial, practice-informed recomm

Conclusion: This workshop seeks to align perspectives, stimulate constructive dialogue, and contribute to the development of a coherent and forward-looking strategic vision for the integration of LM within FM.

ID 1014- A Look at Neglected Populations: Health Education in the Context of Migration and People in Situations of Vulnerability

Biljana PRPA

Department Of Family Medicine, Public Health Institution "primary Health Care Center Doboj", Banja Luka, Bosnie-Herzégovine

Context: Lung, colorectal, breast, cervical, and prostate cancers are the most common malignancies globally, in Europe, and in Republika Srpska. Reducing their morbidity and mortality is a priority in public health. Key strategies include health promotion, early detection, risk factor reduction, and timely treatment initiation. Primary healthcare plays a critical role in implementing preventive measures and screening programs.

Objectives: This study aims to implement preventive measures in primary healthcare, detect malignant diseases early, initiate treatment promptly, and reduce mortality and morbidity through continuous preventive examinations.

Methods: From January 1, 2021, to July 1, 2025, eight family medicine teams systematically invited healthy patients from specific age groups via telephone for preventive mammography, Pap tests, and fecal occult blood tests (FOBT). Participation rates, abnormal findings, and confirmed cancer cases were recorded. The study evaluated adherence to screening recommendations and identified detected malignancies.

Results: Mammography: Of 2,803 eligible women, 1,186 were screened. 23 abnormal findings were detected, including 9 confirmed breast cancer cases. Pap tests: Of 4,525 eligible women, 1,986 were screened. 8 abnormal findings were recorded, including 1 confirmed cervical cancer case. FOBT: Of 6,416 eligible patients, 890 screenings were conducted. 152 abnormal results were identified, 27 patients underwent colonoscopy, and 7 colorectal cancers were confirmed.

Discussion: Organized preventive examinations in primary healthcare have demonstrated their crucial role in early detection of breast, cervical, and colorectal cancers. Participation varied across screening tests, with the highest uptake for Pap tests (approximately 44%), for mammography (around 43%), and lowest for FOBT (about 14%), reflecting barriers such as test perception, fear, or logistical challenges. Early detection enables more effective treatment and improves treatment outcomes. These results underscore the essential role of family medicine teams in conducting continuous and systematic preventive examinations and highlight the need for patient education and reminders to increase participation in prevention programs.

Conclusion: The treatment of malignant disease is multidisciplinary, but preventive examinations form the cornerstone of care. Therefore, it is essential to strengthen the role of primary healthcare in conducting continuous preventive examinations and early symptom recognition, in order to detect the disease at a stage when treatment is most effective.

ID 1347- A Lump On The Run - Can We Spot A Sarcoma In The Jungle?

Giovanna GARCIA GARDINI, Arthur MONTEIRO MARQUES MELLO, Luiza KANADANI CAMPOS DA SILVA, Stefan VILGES DE OLIVEIRA

Faculty Of Medicine Of The Federal University Of Uberlandia, Uberlândia, Brésil

Context: Visceral Leishmaniasis (VL) is a zoonotic disease that may progress to severe clinical forms with high lethality. In the XXX, Leishmania infantum is the main etiological agent. Immunosuppression caused by Human Immunodeficiency Virus (HIV) infection compromises cellular immunity and is associated with increased treatment failure, relapse, and mortality, making VL - HIV coinfection a major public health concern in endemic urban areas such as XXX, XXX, XXX.

Objectives: To characterize reported cases of VL - HIV coinfection in XXX between 2015 and 2024, analyze its impact on VL-related mortality, and summarize evidence-based interventions to improve outcomes in coinfected individuals

Methods: A quantitative and descriptive epidemiological study was conducted using secondary data from the Mortality Information System and the Notifiable Diseases Information System (SINAN) between 2015 and 2024. Sociodemographic variables, HIV coinfection, and mortality were analyzed. A literature review was performed in PubMed and SciELO using the terms "Visceral Leishmaniasis and HIV" combined with "Intervention," "Treatment," or "Prevention."

Results: Between 2015 and 2024, 1,496 cases of Visceral Leishmaniasis were reported in XXX, of which 421 (28.14%) occurred in individuals coinfected with HIV. Coinfected patients accounted for 39.02% of all VL-related deaths. Most coinfected cases (85%) and deaths (78%) occurred among males, with the highest mortality observed in individuals aged 40-59 years. The literature review identified four main intervention axes: optimization of pharmacological treatment, improvement of early and parasitological diagnosis, prediction of treatment failure and relapse using antigen detection tools, and implementation of secondary prophylaxis in high-risk patients.

Discussion: The proportion of VL-HIV coinfection observed in XXX is consistent with other endemic regions and confirms the association between HIV infection and increased VL lethality. Evidence supports liposomal amphotericin B as the preferred treatment for coinfected patients. Diagnostic limitations in HIV-infected individuals highlight the importance of parasitological methods and emerging antigen-based tests. Secondary prophylaxis and adherence to antiretroviral therapy are key strategies to reduce relapse and mortality.

Conclusion: VL-HIV coinfection significantly contributes to VL mortality in XXX. Strengthening early diagnosis, optimizing treatment, implementing prognostic tools for relapse prediction, and adopting secondary prophylaxis may reduce mortality and disease burden.

ID 1277- A national learning community to improve antibiotic prescribing in out-of-hours general practice

Bernadette LENARTOWICZ

None, Warsaw, Pologne

Context: Graves' disease, the leading cause of hyperthyroidism, often overlaps with menopausal transition in women over 50. This coexistence intensifies vasomotor symptoms such as hot flashes and excessive sweating while promoting cardiovascular instability, including hypertension and altered nocturnal blood pressure patterns. Thyroid dysfunction elevates systolic blood pressure and vascular stiffness, while menopause exacerbates risks through estrogen decline and autonomic changes. This case highlights diagnostic and therapeutic challenges in managing these overlapping conditions in primary care.

Methods: A 52-year-old postmenopausal woman presented with a history of Graves' disease treated with thiamazole, accompanied by persistent hot flashes and profuse sweating. She reported recent home blood pressure (BP) spikes—afternoon readings around 150/95 mmHg and morning values near 140/90 mmHg—despite normal clinic measurements (<140/90 mmHg) and heart rates ≤80 bpm without palpitations. Echocardiography showed left atrial wall thickening and ventricular hypertrophy, indicating early left ventricular hypertrophy likely from long-standing undiagnosed hypertension. Thyroid tests confirmed ongoing Graves' activity. Prior attempts to stop thiamazole caused TSH suppression and worsened BP fluctuations. Ambulatory monitoring confirmed episodic spikes.

Originality: This case is noteworthy for illustrating the complex interplay between active Graves' disease, persistent postmenopausal vasomotor symptoms, and masked/white-coat-normal hypertension with home spikes and early echocardiographic evidence of target-organ damage (LVH), where standard attempts to withdraw antithyroid therapy provoked BP instability.

Lessons learned and future implications: This case distinctively features masked hypertension with preserved heart rate in a postmenopausal patient with active Graves' disease. Antithyroid drug withdrawal triggered rebound hyperthyroidism and BP instability despite lacking typical sympathetic symptoms. Early echocardiographic evidence of target-organ damage emphasises the subtle cardiovascular consequences of combined endocrine and menopausal influences.

Discussion: The case illustrates that antithyroid monotherapy may inadequately address cardiovascular effects when hyperthyroidism coincides with menopause. Evening angiotensin receptor blocker administration provides consistent 24-hour control, complementing thyroid management and mitigating risks in this population.

Conclusion: Starting telmisartan 40 mg nightly with low-dose thiamazole 5 mg daily rapidly normalised BP, resolved spikes within weeks. This dual-therapy model offers a safe, practical framework for similar complex presentations in family medicine.

ID 429- A Neglected Disease in a Neglected Community: Cutaneous Leishmaniasis in Ngäbe-Buglé Children

Maéva BARDIN

Dermg, Nice, France

Context: The World Health Organization indicates benefits of art for human health. Multiple approaches are used around the world with psychological, behavioral and social effects, helping both preventing and treating fields. Public policies aim to promote the devlopment of artistic and cultural events in the health care systems.

Objectives: Describe the effects of collective artistic workshop involving patients and healthcare professionals.

Methods: We conducted a qualitative study based on the model of research-intervention. We collected the feedback of the participants in a collective mural painting involving patients and caregivers (also with patient's families). The artistic workshop was supervised by a professional artist. After, we conducted individual interviews with participants according to a previous guide. Each participant gave his consent and anonymity has been respected. We get the autorizations from ethical local comity and the CNIL.

Results: Health benefits have been reported, with both mental and physical therapeutic effects. Creativity and imagination is a way of expression. The workshop gave birth to a fraternal impulse, sharing and social cohesion. It leads to the improvement of relaxation and well-being. This artistic collective experience reduced the anxiety relative to care, it helps patients to relativize and better accept the disease. It rise the quality of live at work for healthcare professionals. The workshop increased the self-esteem and the self-confidence of participants. It place humanity in the center of the care relationship.

Discussion: This workshop shows many positive impacts due to the strenght of the human relationship between participants. The collective creative project involving both patients and heath care professionals and promotes the empowerment by active participation. The collective creative experience allowed self-transcendence thanks to the sublimated energy. The approach combining art and care fits into this notion of global health that consider the person as a whole with their values and experiences. The approach by empathy in the "patient-doctor relationship" without hierachy leads to a true therapeutic alliance.

Conclusion: This study shows that collective artistic workshop helps to creat a better relationship in care. Patients could improve their experience of the disease thanks to artistic expression. It could inspire other projects using art into heathcare.

ID 1971- A new initiative for long waiting time : The review from Family Medicine Orthopaedic Clinic

Aliki TRAIANOU, Katie BROWN, Ula CHETTY

University Of Glasgow, Glasgow, Royaume-Uni

Context: Higher attainment at university is linked with attendance at timetabled teaching sessions. Understanding student motivations and priorities in learning is crucial to enhancing engagement. During the COVID-19 pandemic, education systems worldwide transitioned to online platforms with little preparation. At University of Glasgow virtual tutorials using pre-recorded GP consultations were developed, evaluated positively, and formally integrated into the curriculum. Over the last 2 years attendance at these sessions has been poor. Last year many students failed the written exam and low performance was linked with attendance at timetabled teaching sessions. This study aimed to understand the cause of low attendance and whether the pedagogy and structure of the tutorials was still engaging and appropriate in the post-pandemic era.

Methods: A mixed-methods approach was used, including questionnaires, using Likert scales to assess student attitudes towards online and in-person learning with follow-up focus groups to explore in-depth perceptions about the effectiveness of pedagogical approaches and factors influencing approaches in the post-COVID era.

Originality: This offers a review of the pedagogy of online GP teaching in a UK university and how understanding students educational needs can be used to address curriculum redesign to improve long term attendance.

Lessons learned and future implications: Medical students have competing demands on their time and often take strategic approaches to learning aiming to achieve optimum grades through effective time management and selective study. Self-efficacy and autonomy experienced during remote learning influenced preferences, reducing perceived necessity for live attendance Actively involving students in the creation of learning materials and incorporating student feedback could improve attendance and engagement through building a sense of ownership.

Discussion: The pandemic acted as a catalyst for rapid development in online learning methods and this transition highlighted both opportunities and challenges. While it has offered flexibility, some students have found it difficult to engage with. Online learning has a place in medical curriculums especially when modern day teaching needs to engage large numbers of students from diverse backgrounds with differing needs.

Conclusion: The adoption of innovative educational delivery styles and collaborative efforts between educators and students will be essential in shaping the future of medical education in the post-pandemic era.

ID 1677- A Novel Machine Learning–Based Model to Support Shared Decision-Making for Early Identification of Esophageal Variceal Bleeding Risk in Primary Care Patients With Non–Cancer-Related Cirrhosis

Dinis BRITO [(1)], Ana Rita Magalhães MAGALHÃES [(2)]

(1) Life And Health Sciences Research Institute (icvs), School Of Medicine, University Of Minho, Icvs/3bs, Pt Government Associate Laboratory, Braga, Portugai;b 7 Fontes Family Health Unit, Unidade Local De Saúde De Braga, Braga, Portugal, Braga, Portugal
(2) School Of Medicine; University Of Minho,, Braga, Portugal

Context: Primary Health Care (PHC) is the main point of contact between users and the healthcare system, making the assessment of the quality and performance of its Functional Units (FUs) essential. As respiratory disease management is part of their routine activity, it is relevant to examine how organisational characteristics influence this practice.

Objectives: To assess how the different characteristics of each FU affect their performance in managing respiratory diseases in mainland Portugal, by analyzing several clinical governance tools available on the BI-CSP® platform: the “Global Performance Index”

(IDG_IPDA), the subarea "Disease Management – Respiratory System Diseases," and its associated indicators.

Methods: A cross-sectional observational study was conducted using public data extracted from the BI-CSP® platform, covering 940 FU (USF-B and UCSP) across all Regional Health Administrations (ARS). Indicators analyzed included COPD and asthma follow-up, influenza vaccination coverage, hospitalization rates, and diagnostic proportions. Descriptive statistics, correlation analyses, multiple linear regressions, and multivariate tests (Wilks' Lambda) were applied.

Results: USF-B units, those with medical residents, and those with a higher number of physicians demonstrated better performance across the evaluated indicators. The IDG_IPDA proved to be a statistically significant predictor in nearly all models. The regions defined by the former ARS also exerted a statistically significant influence on the outcomes. Conversely, hospitalizations due to pneumonia and asthma were not explained by the organizational variables included in the analysis.

Discussion: Performance in respiratory disease management is associated with the organizational model, the presence of medical residents, physician staffing levels, and the regional context. Strategies aimed at strengthening the USF-B model, enhancing clinical training, and promoting regional equity may improve care outcomes. The cross-sectional nature of the data used prevents the establishment of causal relationships between the organisational characteristics of the UF and the outcomes obtained. Although statistically significant associations are identified, it is not possible to determine with certainty whether these variables were the direct cause of the variations in performance indicators.

Conclusion: The performance of FU in the management of chronic respiratory diseases in PHC in Portugal is significantly associated with several organisational characteristics, such as pay-for-performance schemes, which may influence priorities in terms of public investment.

(5) Aldoar Family Health Unit, Porto, Portugal

Context: Lifestyle Medicine (LM) is strongly recommended by leading international organisations, including WHO, ADA, and AHA, for the prevention and management of chronic diseases. Despite robust evidence, many family doctors report difficulties integrating structured lifestyle interventions into routine consultations. These challenges stem from time constraints, limited practical tools, uncertainty about how to initiate interventions, and insufficient knowledge and experience, which ultimately undermine confidence. This workshop provides a simple, operational framework—grounded in recognised guidelines—to support the effective and realistic use of LM within everyday primary care practice.

Objectives: Understand key international LM recommendations relevant to primary care. Identify practical, stepwise strategies for integrating lifestyle interventions into time-limited consultations. Apply evidence-based approaches to motivational counselling and behavioural change monitoring. Analyse real clinical cases to understand intervention pathways and recognise achievable outcomes.

Teaching method and workshop: A highly interactive format combining short conceptual inputs, facilitated small-group discussions, analysis of real patient cases, practical communication exercises, and collaborative

reflection. Structured tools and checklists will be introduced to supp

Expected outcomes: Participants will gain concrete skills to integrate LM into brief consultations, operationalise evidence-based recommendations, and tailor interventions to individual patient contexts. They are expected to leave equipped to apply strategies that improve a

Conclusion: This workshop offers a pragmatic, evidence-based, and highly transferable approach to strengthening the role of primary care in chronic disease prevention and management through Lifestyle Medicine.

ID 769- A Purple Finger Seen in the Family Medicine Setting

Luigi CECCARONI, Mario CALÒ

Ausl Romagna, Cesena, Italie

Context: Injection therapy is a widely adopted intervention in the management of musculoskeletal and inflammatory disorders within primary care. Traditionally performed using blind techniques based on anatomical landmarks, these procedures are increasingly supported by point-of-care ultrasound. The growing availability of portable ultrasound devices has expanded their potential role in General Practice, offering new opportunities to improve diagnostic accuracy and therapeutic precision.

Methods: This work is based on a narrative review of the scientific literature, including clinical guidelines, comparative studies, and case series addressing blind and ultrasound-guided injection techniques. Published evidence was integrated with clinical experience in General Practice to evaluate feasibility, safety, effectiveness, and applicability in routine Primary Care settings.

Originality: This study specifically focuses on the implementation of ultrasound-guided injection therapy in General Practice, a setting traditionally underrepresented in interventional musculoskeletal research. It highlights the role of the General Practitioner not only as a referrer but also as an active provider of image-guided procedures.

Lessons learned and future implications: Ultrasound guidance consistently improves needle placement accuracy, reduces procedural complications, and enhances patient confidence. However, successful implementation requires structured training, access to appropriate technology, and organisational support. Future integration may redefine the scope of procedural skills in Primary Care.

Discussion: Compared with blind techniques, ultrasound-guided injections demonstrate superior clinical outcomes, particularly in anatomically complex or previously treated sites. While blind approaches remain effective in selected cases, ultrasound guidance provides added value in terms of safety and therapeutic efficacy.

Conclusion: Injection therapy remains a cornerstone of musculoskeletal care in General Practice. Ultrasound-guided techniques represent an important advancement, enabling General Practitioners to deliver safer, more precise, and patient-centred care. With adequate training and resources, their integration into Primary Care has the potential to significantly improve clinical outcomes and optimise healthcare delivery

ID 1585- A revolution from within: Liberty, equality, fraternity- needed now more than ever

Aslinur OZMEN [(1)], Emirhan OZMEN [(2)], Ismail KASIM [(3)], Ebru UĞRAŞ [(1)]

(1) Department of Family Medicine, Ankara Yıldırım Beyazıt University Faculty of Medicine, Ankara, Türkiye
(2) Department of Computer Engineering, Hacettepe University, Ankara, Türkiye
(3) Department of Family Medicine, Ankara Bilkent City Hospital, Ankara, Türkiye

Context: Atherosclerotic cardiovascular disease (ASCVD) is a major cause of death in Türkiye and worldwide. Because it progresses silently, early risk prediction is critical. Current risk

scoring systems are based on standard factors and may overlook metabolic problems and insulin resistance. New data suggest that novel metabolic markers and machine learning, particularly in primary care settings, can help better predict risk.

Objectives: This research sought to create a better model for predicting the risk of ASCVD in men aged 40–65. It did this by including new factors related to metabolism and insulin resistance and by testing how well machine learning models could predict risk. The study checked if including HbA1c, TSH, SPISE, and AIP, along with standard risk factors, made the prediction of ASCVD risk more accurate.

Methods: This case–control study looked at 350 men between 40 and 65 years old who visited the Family Medicine clinic at Ankara Bilkent City Hospital. Of the participants, 175 had ASCVD and 175 served as controls. Lifestyle and laboratory data were collected, and predictive modeling was conducted using ROC analysis and machine learning algorithms, including SVM, decision trees, and random forest models.

Results: Older age, family history, obesity, high systolic blood pressure, high triglycerides, low HDL-Cholestrol (HDL-C) and high HbA1c were associated with atherosclerotic cardiovascular disease. ROC analysis showed that AIP and SPISE better discriminated cases from those with normal lipid markers. The Support Vector Machine (SVM) model had the best among machine learning algorithms.

Discussion: The study results suggest that metabolic and insulin resistance factors greatly improve ASCVD risk prediction compared to standard risk factors. The strong performance of SPISE and AIP shows they are clinically relevant for early risk classification. Machine learning models, specifically SVM, showed better discrimination by assessing many interacting variables at once, which addresses some limits of standard scoring systems.

Conclusion: Incorporating novel metabolic markers such as SPISE, AIP, HbA1c, triglycerides, physical activity level, and smoking exposure into machine learning–based models significantly improves ASCVD risk prediction. The SVM model showed high accuracy and discriminatory power, suggesting strong potential for personalized, data-driven ASCVD risk assessment tools that can be effectively integrated into primary care practice.

ID 1454- A routine case of chest pain?

May FIANI, Abdelhak EL HAOUARI

Dmg, Amiens, France

Context: In France, the 2016 health system modernization law recognized adapted physical activity (APA) as a therapy in its own right. For PWD, despite the possible APA prescription by the general practitioner, access to sports practice remains a real challenge, due to persistent social, cultural and material obstacles. What are the effects of APA in PWD aged 18 to 59 found in the literature?

Objectives: Mapping in the literature the effects of APA for PWD aged 18 to 59 years.

Methods: A double-blind scoping review was carried out using Rayyan software. She queried six databases (PubMed, Cochrane, Embase, Scopus, SportDiscus et Web of Science) on the concepts of disability and physical activity, from 2020 to 2025, for the population aged 18 to 59.

Results: Out of 9749 articles, 57 of them were included. The main effects observed were to improving the quality of life among people with disabilities. In short, it acts on several levels: • Physical (reduction of pain, better mobility), • Psychological (well-being, vitality), • Social (inclusion, interactions), • Functional (autonomy in activities of daily living).

Discussion: Strength: Prisma ScR criteria respected. Limitations: heterogeneity of studies, the under-representation of certain pathologies and the lack of standardization of assessment tools limit comparability. This review highlights the richness and diversity of APA interventions, confirming its essential role for the health, autonomy and quality of life of PWD.

Conclusion: Despite the growing development of adapted sport encouraged by public authorities, APA remains insufficiently implemented. This review confirms the role of APA in improving the overall health of PWD, as well as improving their quality of life. The APA must therefore be promoted by general practitioners, and society must allow PWD to access it both in supporting the deployment of activity proposals, assistance with transport and the accessibility of structures. PWDs need access to common rights and full citizenship. The APA is one of them. An assessment of the specific needs of PWD to practice APA would be relevant.

ID 439- A Seven-Year Journey of Prevention: Integrating Physical and Mental Health in an Evolving Employee Wellness Program (2019–2025)

Maor LEWIS, Zacay GALIA, Falah NOGA, Albukrek DOV, Heymann ANTHONY

Meuhedet Health Services, Tel Aviv, Israël

Context: Managing diabetes in frail patients is complex due to varying clinical factors. The optimal HbA1c target for each level of frailty remains unclear. Existing thresholds are based on expert opinion, but evidence guiding individualized targets by frailty severity is limited.

Objectives: 1. What is the association between diabetes control and mortality among community-dwelling frail older adults. 2. What is the optimal HbA1c target for each level of frailty.

Methods: A retrospective cohort study of patients aged ≥75 with type 2 diabetes, insured by Meuhedet Health Services (MHS), from 2015 to 2022. Inclusion required continuous enrollment in MHS, ≥2 years of medical history, ≥2 HbA1c values ≥6.5%, and at least one antidiabetic prescription. Exclusions were type 1 diabetes, missing recent HbA1c, and conditions affecting HbA1c reliability (e.g., G6PD deficiency, anemia, splenectomy). HbA1c category was defined using the most recent value in the year prior to cohort entry; frailty was assessed using a validated index based on ≥2 years of records. Follow-up began at age 75 and continued until death or December 31, 2024. The primary outcome was all-cause mortality. Analyses will be stratified by frailty level to explore the association between glycemic control and mortality across frailty categories. Statistical analysis included Cox proportional hazards models with HbA1c categorized as <7% (reference), 7–7.9%, and ≥8%, adjusting for age, sex, SES, diabetes duration, and insulin use. Effect modification by frailty was assessed using interaction terms and penalized splines. Kaplan-Meier curves and subgroup/sensitivity analyses were also performed.

Results: No results yet.

Discussion: No results yet.

Conclusion: No results yet.

ID 119- A Study on Factors Affecting the Quality of Life of Elderly Cancer Survivors

Tamara SINOŽIĆ [(1)], Juraj SINOŽIĆ [(2)], Ema RALIĆ [(2)]

(1) Assistant Professor, Mošćenička Draga, Croatie
(2) Medical Student, Rijeka, Croatie

Context: To present a case of a patient with dermatological changes occurring one month after a tourist trip to Zanzibar, and to outline the diagnostic and therapeutic procedures undertaken by the family physician and dermatologist for the confirmation and treatment of the parasitic disease Larva migrans.

Methods: A 54-year-old female presented to the family physician with skin changes on the right sole, accompanied by pruritus. She was afebrile and did not report any systemic symptoms. The patient had a medical history of Hashimoto's thyroiditis and was being treated with levothyroxine. Upon inquiry, she reported traveling to Zanzibar a month prior, where she had walked barefoot on sandy beaches.

Originality: A review of the literature was conducted focusing on dermatological conditions associated with travel to Zanzibar

and the surrounding East African region. The findings support cutaneous larva migrans as a common travel-related parasitic dermatosis linked to barefoot exposure on sandy beaches and are consistent with the clinical presentation in our patient.

Lessons learned and future implications: A detailed travel history is essential for recognizing travel-related dermatological conditions and enables early suspicion of parasitic infections such as cutaneous larva migrans. Awareness of region-specific diseases, supported by literature review, allows timely referral and effective treatment, leading to complete patient recovery.

Discussion: Upon initial examination by the family physician, a small papule was observed, which developed into a moving erythematous serpentine lesion. The blood count was normal. Based on the epidemiological history and clinical findings, a working diagnosis of Larva migrans was made. The patient was referred for further diagnostic and therapeutic procedures to the dermatology department of the clinical hospital center. Subsequent diagnostic tests confirmed the diagnosis, and the patient was prescribed Albendazole 400 mg (to be taken with a fatty meal) once daily for three days. After completing the treatment, the skin lesion resolved completely without any residual effects.

Conclusion: A thorough medical history, appropriate knowledge of travel medicine, and a review of the relevant literature provide valuable guidance for family physician in diagnostic and therapeutic decision-making. In the presented case, this approach enabled timely diagnosis and successful treatment of parasitic disease Larva migrans

ID 2073- A Study on General Practitioners' Knowledge, Awareness and Current Management Status of Mild Cognitive Impairment

Daniela PETRAGLIA [(1)] , Mariacristina ARBASI [(1)], Mauro MORETTO [(1)], Matteo CARUSONE [(1)], Elena QUARANTELLI [(1)], Marco CUPARDO [(2)]

(1) Simg, Piacenza, Italie
(2) Simg, Bologna, Italie

Context: In last few years Italy has faced ad increase in Emergency Department (ED) admissions, mostly for non-urgent conditions: although institutions often attribute this trend to perceived General Practice's (GP) inefficiency, evidence remains scarce.

Objectives: This study analyses inappropriate ED visits, quantifying the proportion of patients bypassing GP consultation and evaluating the GP's effectiveness as a gatekeeper for emergency services' access.

Methods: This descriptive observational study examined 300 ED admissions among patients of four GPs in Piacenza, Italy. For each case, we recorded: mode of referral (self-referral vs. GP-mediated or specialist-mediated access), prior contact with GP, triage code and clinical inappropriateness (feasibility of management within Primary Care). Data were analysed using absolute frequencies and proportions.

Results: Most patients (84%, n=251) did not consult their GPs before accessing to the ED and 87% (n=261) were self-referred, occasionally even after prior medical consultation with their GPs. Among the 234 self-referred visits without GP contact, only 43% (n=100) were deemed clinically appropriate, compared to 79% (n=34) of the 43 visits filtered by the attending physician. While minor triage codes accounted for 67% (n=200) of cases, clinical judgment determined that only 51% (n=154) of total visits were inappropriate. Notably, only 2% (n=5) of self-presentations followed a lack of response from the GP; among these, 3 cases were assigned "major" triage codes suggesting time-dependent conditions.

Discussion: Approximately half of ED accesses are clinically unnecessary and manageable within a Primary Care setting. High ED utilization is primarily driven by patient self-initiative rather than GP unresponsiveness, which accounted for a negligible fraction of self-refferals. Conversely, when General Practice performs a gatekeeping role, ED utilization is more frequently appropriate. Minor triage codes not always correspond to

inappropriateness of access according to clinical judgment (it is standard practice to assign minor codes to obstetric or orthopedic conditions requiring urgent instrumental diagnostics).

Conclusion: The patient's tendency to bypass the GP's gatekeeping function, rather than a presumed inefficiency of General Practice is the primary driver of ED overcrowding from non-acute presentations. Lack of GP responsiveness is a misconception. Study limitations include: small sample size and potential confirmation bias.

ID 206- A Visual Narrative of Inequality: Analyzing Paternalism and Social Determinants in 19th-Century Medical Art

Romario HENRIQUE DA SILVA [(1)], Manoel Vieira De MIRANDA NETO [(2)]

(1) Albert Einstein Israelite College Of Health Sciences, São Paulo, Brésil
(2) University Of São Paulo, São Paulo, Brésil

Context: Advanced practice nursing roles are promoted internationally to improve access and quality in primary health care (PHC). In Brazil, nurses in PHC already perform autonomous clinical work, but the extent to which their consultations include activities aligned with advanced practice remains unclear.

Objectives: To analyze indicators of advanced clinical activities within nurses' routine PHC consultations; to identify which activities are most and least frequent; and to inform implementation through a strategic guide.

Methods: Descriptive exploratory quantitative study using secondary data from a multicenter database of recorded nursing consultations in three Basic Health Units (Unidades Básicas de Saúde, UBS) in Brazilian municipalities. Eighteen nurses were included. Seventy three consultations were analyzed using a structured instrument based on seven International Council of Nurses clinical activities for advanced practice. These activities were prescribing medicines, ordering tests, indicating treatments, making clinical diagnoses, holding responsibility for a patient panel, referring and counter referring, and being recognized as a first point of contact. Frequencies and proportions were calculated. Associations between consultation type and selected activities were tested with significance set at $p<0.05$.

Results: Most nurses were women (72.2%). Consultations were mainly in women's health (75.3%), followed by older people's health (12.3%). Activities related to first contact and responsibility for a patient panel were frequent, reflecting core nursing work in PHC. Activities requiring higher clinical complexity showed limited occurrence and varied by consultation type. There was a statistically significant association between consultation type and prescription being absent versus performed ($p=0.0013$). When restricted to women's health consultations, this association was not significant ($p=0.1798$). Similar patterns were observed for ordering tests ($p=0.0515$) and documenting clinical diagnosis ($p=0.7408$).

Discussion: The findings suggest that Brazilian PHC nurses consistently deliver longitudinal, first contact care, but advanced clinical decision making tasks such as prescribing, test ordering, diagnosis documentation, and counter referral are not yet routine across consultation types. Local protocols, training, and governance may influence this variability.

Conclusion: Indicators of advanced practice are present but uneven. Strengthening regulation, education, and service protocols may support safer expansion of advanced clinical activities beyond women's health and increase equity in access to PHC services.

Jagiellonian University Medical College, Krakow, Pologne

Context: Family physicians in Poland increasingly encounter patients who speak neither Polish nor English. This study aims to identify the main challenges, coping strategies, and support needs among primary care physicians when communicating with these patients.

Objectives: To identify the types of language bariers Polish primary care physicians face.

Methods: A cross-sectional survey is being distributed to family physicians working in primary care across Poland. Data collection began in September 2025 and is ongoing. The questionnaire assesses encounter frequency, perceived communication problems, languages involved, current coping strategies, available resources, and desired support. Preliminary results are presented here.

Results: Preliminary data include 19 respondents, predominantly female (79%), family medicine specialists (74%), and practicing in cities >100,000 population (63%), with a mean age of 48.6 years. 32% reported frequent (weekly or daily) encounters with non-Polish/English speaking patients. For questions on languages encountered, challenges, coping strategies, and support needs, respondents could select multiple options. Ukrainian was identified as the most common language barrier (100%), followed by Russian (47%) and Vietnamese (37%). The most frequently reported problems were difficulty obtaining a thorough history (53%), uncertainty about patient understanding (53%), and difficulty explaining medical advice (47%). 26% of surveyors reported concerns about increased medical error risk. Coping strategies relied predominantly on improvised solutions: family members as interpreters (89%) and smartphone translation applications (84%), with many respondents using both approaches. 68% reported having no dedicated translation resources in their practice. 63% considered current institutional support inadequate, and 21% had experienced situations where lack of professional interpretation potentially endangered patient safety. Priority needs included improved technology support for translation applications (63%) and funded access to professional interpreters (58%).

Discussion: Preliminary findings indicate that language barriers may represent a common everyday challenge in Polish primary care. Early data suggest physicians rely on improvised solutions while lacking dedicated resources.

Conclusion: Final results will determine the scope of these challenges and whether systemic support — including interpreter services, translation technology, and collaborative networks are needed to ensure effective practice and equitable access to care.

ID 2171- About a case" Bilateral papilla edema in adulthood focused from Primary Care"

Line RIQUEL, Emeline LEGUENNEC

Ufr Santé, Saint-Pierre, Réunion

Context: The university degree “meditation and therapeutic relationship” exists at the University in France since 2020. It is a theoretical and practical training of three types of meditation: mindfulness, full- presence and yoga. The health benefits of meditation have been scientifically demonstrated. This study aimed at describing the contributions of this degree for the participants, on a personal level and on a professional level within their therapeutic relationship.The university diploma program consisted of lectures and workshops to learn how to lead meditation sessions of these approaches.

Objectives: The main objective was to report on the benefits of University Diploma (DU) in “Meditation and Care Relationship” to participants, from both a personal perspective and from the perspective of care relationship. Secondary objectives wanted to evaluate the strengths and weaknesses of this university degree and consider initial training.

Methods: This is a qualitative study on 17 participants of this university degree,with data collection by individual semi-directed interviews and analysis by grounded theory.

Results: The participants have acquired ways to reduce stress and work on their emotions. They

developed qualities of attention, presence, empathy and communication, that improved the quality of doctor- patient relationship.The personal benefits were: increased perceptual abilities,action on attention, concentration, memory and non-judgment; pride, self-esteem, and self-confidence.On a professional level, they experienced an increase in empathy,.new skills for stress management and experimenting with a new caregiver role: they identify the real dimension of care relationship applied in the biopsychosocial notion of health.This learning experience also allowed them to improve their teaching methods.

Discussion: The university degree “meditation and therapeutic relationship” had a positive impact on the participants, on a personal and professional level. Such training is to be encouraged within universities during medical studies.This corresponds to what is written in the literature, but this university diploma is completely original because it informs us on the specific contributions of each approach.

Conclusion: The diploma " meditation and therapeutic relationship " talks about the concept of " patient-centered approach". It is part of non-pharmacological interventions.An initial training to healthcare professionals could be proposed.. Keywords university degree, medical studies, meditation, mindfulness, full- presence, yoga, therapeutic relationship, doctor- patient relationship

ID 1763- Acceptability and feasibility of an evaluation table to assess the competency of general medicine interns during ambulatory rotations in XXX.

Lília Pacheco ALMEIDA, Mariana Raposo FERREIRA, Bruno TAVARES, Felipe VENTURA, Daniela LIMA

Centro De Saude Da Ribeira Grande, Ribeira Grande, Portugal

Context: Cervical cancer screening is an effective strategy to reduce morbidity and mortality. However, participation rates remain suboptimal in many populations, despite organised screening programmes. Primary care plays a key role in implementing population-based screening and addressing barriers to participation. Mass screening initiatives conducted in primary care settings provide an opportunity to evaluate real-world adherence and to explore factors influencing women’s decisions to participate or not.

Objectives: To assess adherence to cervical cancer screening and to identify facilitators and barriers to participation among eligible women during a mass screening initiative in a primary care setting.

Methods: An observational cross-sectional study is being conducted during a cervical cancer mass screening initiative implemented in a primary care unit. Eligible women, according to national screening recommendations, are actively invited to participate. Screening uptake is registered, and data are collected using a structured questionnaire. Variables include sociodemographic characteristics, previous screening history, knowledge about cervical cancer screening, perceived benefits and perceived barriers. Data collection is ongoing at the time of abstract submission.

Results: Data analysis will describe screening adherence rates and identify the main facilitators and barriers associated with participation and non-participation. Associations between selected sociodemographic and clinical variables and screening uptake will be explored. Preliminary and final results will be presented at the conference.

Discussion: Understanding facilitators and barriers to cervical cancer screening in a primary care setting can inform strategies to increase participation and reduce inequities. Active involvement of family doctors, targeted education, and addressing modifiable barriers are key elements to improve adherence. Mass screening initiatives also provide an opportunity to assess population-level behaviour and inform future preventive programmes.

Conclusion: Mass cervical cancer screening in primary care is effective not only for early detection but also for identifying modifiable barriers to participation. Insights from this

initiative can support tailored interventions to enhance adherence and equity in preventive healthcare, reinforcing the central role of family doctors in promoting women's health.

Antonio Augusto FARIA CASTRO, Gabriela RODRIGUES GARCIA, Henrique CARVALHO GOES, Daniela SILVEIRA, Michele Cristina DE SOUSA PEDROSO

São Leopoldo Mandic Araras, Araras, Brésil

Context: Maternal mortality is defined as the death of a woman related to pregnancy or childbirth, caused by direct complications, such as hemorrhage and hypertension, or indirect complications related to pre-existing diseases aggravated by pregnancy. Studying these causes is essential to improve care and reduce maternal deaths in the city of São Paulo.

Objectives: To describe the socioeconomic profile of maternal deaths and the maternal mortality ratio by type of obstetric cause in the city of São Paulo, from 2013 to 2023.

Methods: This is an ecological, descriptive, and quantitative epidemiological study using data from the Mortality Information System (SIM) and the Live Birth Information System of São Paulo (2013–2023). Sociodemographic data of maternal deaths were included: age group, education, marital status, place of occurrence, and cause of death. To calculate the maternal mortality ratio by cause of death, the number of live births in São Paulo was used, stratified by year. The specific maternal mortality ratio by type of cause was used to construct the time series graph.

Results: Maternal deaths in the municipality of São Paulo in the period from 2013 to 2023* occurred predominantly in women aged 30 to 39 years (48.49%), white (46.99%), single (55.21%), took place in hospitals (96.06%), and were due to direct obstetric causes (50.92%). The maternal mortality ratio due to direct causes was higher from 2013 to 2019 and from mid-2021 to 2023. From 2019 to early 2021, the predominant obstetric cause was indirect. Throughout the period, the unspecified obstetric maternal mortality ratio was the lowest among the causes; however, it increased in 2020, similar to the indirect causes.

Discussion: Advanced maternal age and single status indicate social vulnerability and increased risk. The predominance of in-hospital direct causes suggests failures in emergency care. The shift to indirect causes reflects the impact of COVID-19 mortality and health system overload.

Conclusion: Maternal mortality in São Paulo between 2013 and 2023 highlights social inequalities and weaknesses in women's health care. The predominance of direct causes and the oscillation during the pandemic reinforce the importance of public policies that guarantee access, quality, and equity in care, especially in prenatal care and childbirth.

ID 1387- Acral fibrokeratoma: recognizing a rare but treatable skin lesion

Fariba YADOLAHI

Faculty Of Medicine, Zahedan University Of Medical Sciences, Zahedan, Iran (République islamique d')

Context: Patients with cancer may be at increased risk of fractures. Fractures result in morbidity and mortality and reduced quality of life. Addressing the morbidity and mortality of cancer is an important public health concern. This is the first study the risk of fracture in patients with various types of cancer in the southeast of Iran.

Objectives: The Study aims to investigate the associations of cancer diagnoses with the risk of fractures among individuals with cancer compared with the fracture risk among adults without a history of cancer.

Methods: We performed a study using population-level healthcare administrative databases from the southern province of Iran, from January 2014 to December 2024. Diagnoses were identified through the Iran

Cancer Registry. In individuals with cancer who were more recently diagnosed (<5 years since diagnosis) or who had chemotherapy.

Results: This study included 18722 individuals with cancer (mean [SD] age, 66.9 [6.2] years; [79.1%] female) and 16,357 noncancer individuals (mean [SD] age, 67.3[8.3] years; [83.6%] female). An increased risk of fractures, within the first year after diagnosis, was seen in patients with primary bone cancer (OR_3.42, 95% CI: 1.33_7.06), multiple myeloma (R_4.91, 95% CI: 2.81_8.12), metastases to the bone (OR_5.178, 95% CI:3.49_6.99), metastases to other organs than bone (OR_1.91, 95% CI: 1.61_2.18), lung cancer (OR_1.90, 95% CI: 1.51_2.38), and cancer of the liver, gall bladder and pancreas (2.14, 95% CI: 1.39_3.21), cancer of the breast (2.23, 95% CI: 1.41_3.22). In patients with prostate cancer, an increase in fracture risk was observed over time within the first year after diagnosis.

Discussion: This study showed fractures associated with various cancers in patients with cancer and significantly affects bone health. The findings of our study are concordant with prior studies demonstrating an increased fracture risk in patients with solid cancers.

Conclusion: Education of patients, lifestyle modification can improve patient outcomes. This may have implications for which patients should be selected for prevention against fractures. Patients with cancer are at modest risk of fractures compared to non-cancer controls, particularly for breast, prostate, and multiple myeloma.

ID 1576- Actinomycosis : A Forgotten Chronic Infection About 22 cases in Tunisia

Lou RICHELLE, Anne-Marie OFFERMANS, Vincent HUBERLAND

Département De Médecine Générale De L'université Libre De Bruxelles, Brussels, Belgique

Context: Domestic violence (DV), due to its high prevalence and associated morbidity, constitutes a major public health concern. As frontline healthcare providers, general practitionners (GPs) play a pivotal role in the identification of DV and must be adequately trained to deliver appropriate medical and psychological care to direct and indirect victims, as well as to perpetrators. The XXX from XXX has developed well-established expertise in this domain, as evidenced by several peer-reviewed publications, academic theses, clinical guidelines, and the ongoing delivery of Continuing Medical Education programs focused on domestic violence for primary care professionals.

Objectives: To strengthen the capacity of primary healthcare professionals to detect violence at an early stage and to ensure appropriate biopsychosocial support for individuals concerned.

Teaching method and workshop: The professional stance and the nature of the relationship established with the patient are key determinants in both the disclosure of violence and the development of sustainable change in situations involving violence. Grounded in active learning pedagog

Expected outcomes: To strengthen participants' clinical awareness and to provide them with evidence-based professional attitudes and clinical tools, from the first patient encounter through to appropriate biopsychosocial approach

Conclusion: This workshop aims to enhance participants' skills in managing DV, a widespread but frequently underscreened problem, which is often inadequately addressed by GPs, resulting in both patient revictimization and iatrogenic medicalization.

ID 1015- Actionable Awareness as a Predictor of Preventive-Care Uptake: Analysis of a Literacy Threshold in Singapore Rental-Flat Residents

Pemra CÖBEK UNALAN, Buğu USANMA KOBAN, Afranur SENTÜRK

Marmara University School Of Medicine Department Of Family Medicine, İstanbul, Türkiye

Context: The use of artificial intelligence (AI) in healthcare both enhances patients' quality of life and reduces the workload of healthcare professionals.

Objectives: To determine the extent to which physicians, midwives, and nurses working in primary care utilize AI tools, as well as to assess their levels of AI literacy, AI-related anxiety, and attitudes toward AI-based healthcare services.

Methods: This descriptive, observational research design consisted of a total of 337 participants, including 170 physicians and 167 midwives/nurses, were selected using simple random sampling. Data were collected through face-to-face interviews between July 25 and August 22, 2025. The data collection instruments included the Participant Information and AI Use Form, the Meta Artificial Intelligence Literacy Scale (MAILS), the Artificial Intelligence Anxiety Scale, and the General Attitude Toward Artificial Intelligence in Health Services Scale. Data were analyzed using SPSS 27.0 and the PROCESS macro version 4.2. Independent Samples t-Test, ANOVA, Pearson Correlation Analysis, and Mediation Analysis were used, with a statistical significance level set at $p<0.05$.

Results: Results revealed that the most common professional uses were for reading resources and translation, while the use of virtual assistants, automated reporting, and triage applications remained limited. The main concerns reported by participants included data privacy, lack of trust in AI, insufficient legal regulations, and integration difficulties. Overall AI literacy levels were below average, with the highest competence in using AI tools and the lowest in developing new AI applications. AI anxiety levels were moderate, with ethical concerns and fear of job loss being the most prominent.

Discussion: Attitudes toward AI were generally moderate, with positive attitudes being more prevalent. Physicians demonstrated higher AI literacy than midwives and nurses, while younger participants scored higher than older ones. Women exhibited higher levels of AI-related anxiety. Mediation analysis indicated that AI anxiety partially mediated the effect of AI literacy on attitudes; as AI literacy increased, anxiety levels decreased, leading to more positive attitudes toward AI use in healthcare.

Conclusion: In conclusion, enhancing the AI awareness and literacy levels of primary healthcare professionals may reduce their concerns regarding data privacy and security, strengthen their willingness to integrate AI technologies into clinical practice.

ID 622- Active Arterial Mid-Gut Bleeding Identified in the Prehospital Setting: A Case Enabling Timely Specialized Management

Hubert MAISONNEUVE [1] , Racha ONAISI [2], Christine PIETREMENT [3]

(1) Primary Care Institute-University Of Geneva, Geneva, Suisse
(2) Department Of General Practice-University Of Bordeaux, Bordeaux, France
(3) Faculty Of Medicine Reims-University Of Champagne Ardenne, Reims, France

Context: Numerous residents suffer from stress, anxiety, which may be acutely exacerbated by stressful situations such as being on call. When confronted with uncertainty situations, residents experience a mismatch between their theoretical knowledge and their clinical reasoning skills. In a previous study we observed high levels of cognitive weariness and anxiety in residents being on call in the paediatric emergency department, and the reduction of their cognitive weariness by training clinician-educators in the supervision of clinical reasoning.

Objectives: We sought to inform the findings of our previous research by exploring in depth the experience of on-call residents in the paediatric emergency department, including: the factors that impact their well-being, and how supervision of their clinical reasoning might change it.

Methods: We performed a qualitative study using semi-structured interviews. We interviewed medical residents who were on call in the emergency department, mentored by

supervisors who had received specific training in the supervision of clinical reasoning.

Results: The findings revealed two opposing profiles of how residents experience being on call and having their clinical reasoning supervised. First, there were those who expressed marked discomfort, characterized by anxiety, a strong need for supervision, a fear of being judged by the supervisor, and a major impact of physical fatigue. Residents with this profile seem to be at risk of developing burnout. The second profile expressed little unease, had a sense of self-efficacy, a feeling of personal competence, a high level of self-confidence, greater tolerance of uncertainty, and little difficulty with making decisions.

Discussion: Clinical experience alone may not linearly move residents from basic to advanced reasoning. Targeted supervision techniques can identify these difficulties and provide remediation strategies. In emergency departments, lack of experience and few operational scripts hinder non-analytical reasoning, requiring systematic data analysis and high working-memory capacity. The study links working-memory load to cognitive fatigue, a burnout component, and suggests that improving reasoning scripts could reduce anxiety and burnout.

Conclusion: Supervision of clinical reasoning based on questioning techniques seems to participate to promote development towards second profile, with greater tolerance of uncertainty, ease with decision-making, and a reinforced sense of belonging to a team.

(1) Department Of Family Medicine, Izmir City Hospital, Izmir, Türkiye
(2) Department Of Family Medicine, Dokuz Eylul University Faculty Of Medicine, Izmir, Türkiye

Context: Effective communication is the cornerstone of Family Medicine. Studies show that patients forget up to 80% of medical information provided verbally. Visual aids significantly improve health literacy and adherence; however, many General Practitioners (GPs) hesitate to use visuals due to a lack of artistic skill or time constraints. The rapid emergence of Generative AI (e.g., DALL-E, Midjourney) offers a novel solution, but it also raises questions regarding accuracy, ethics, and the human element of the consultation.

Objectives: This interactive workshop aims to empower GPs to visualize complex medical conditions using two distinct approaches: traditional "napkin sketches" and modern "AI prompting." Participants will: Learn to simplify complex pathophysiology into basic, hand-drawn schematics (analog). Acquire skills in "Prompt Engineering" to generate instant, personalized patient education visuals using AI tools (digital). Critically evaluate the risks (e.g., anatomical hallucinations) and benefits of AI versus the empathy of hand-drawn explanations.

Teaching method and workshop: The session will follow a "Compare and Contrast" structure (60 mins): Introduction (5 min) Part 1 (15 mins): The Pen (Analog): Participants will be challenged to draw a specific condition (e.g., Heart Failure mechanisms) using simple geometric shapes. The

Expected outcomes: By the end of this workshop, participants will have an expanded toolkit for patient communication. They will leave with the confidence to use simple sketches for immediate explanation and the technical know-how to utilize AI tools responsibly for creating

Conclusion: The key takeaway is the importance of choosing the right method at the right time, balancing human warmth and clarity with the ethical use of technology in clinical communication.

Context: Despite rapid artificial intelligence integration in healthcare, family physicians receive inadequate training to critically evaluate and safely apply AI-based clinical tools. Studies show strong physician interest but limited confidence and skills, leaving primary care providers unable to assess AI tool validity, understand performance metrics, or identify potential biases.

Objectives: To evaluate the effectiveness of a structured continuing professional development course in improving family physicians' knowledge, attitudes, and self-efficacy regarding artificial intelligence and machine learning applications in primary care.

Methods: Pre-post intervention study of Israeli family physicians enrolled in a two-day course (November 27-28, 2025). The curriculum covered: machine learning fundamentals (supervised/unsupervised learning, overfitting, AUC, calibration, neural networks), large language models in medicine, hands-on predictive modeling demonstrations, and critical appraisal of AI clinical prediction studies. Three questionnaires assessed: (1) ML knowledge (7 multiple-choice questions on overfitting, calibration, supervised learning, LLM mechanisms); (2) attitudes toward AI across 11 clinical scenarios (4-point Likert); (3) self-efficacy in AI-assisted decision-making (adapted validated scale, 4-point Likert). Paired t-tests and Wilcoxon signed-rank tests were used ($p<0.05$).

Results: Of 62 enrolled physicians, 40 completed pre-intervention and 27 completed both assessments (67.5% completion rate). Significant knowledge improvement was observed (pre: 0.51, post: 0.71; 39% increase; $p<0.001$). No significant changes in attitudes (pre: 2.40, post: 2.39; $p=0.93$) or self-efficacy (pre: 3.30, post: 3.36; $p=0.14$). High baseline attitudes and self-efficacy scores suggest potential ceiling effects.

Discussion: This study demonstrates that a multi-modal AI literacy course significantly improves family physicians' foundational machine learning knowledge. The 39% improvement shows complex technical concepts can be effectively taught to practicing physicians without computational backgrounds. Unchanged attitudes and self-efficacy, despite high baseline scores, may reflect existing positive AI perceptions among self-selected participants rather than intervention ineffectiveness. The limited sample size (n=27) warrants validation in larger cohorts.

Conclusion: A focused continuing professional development intervention effectively enhances family physicians' AI literacy, providing essential skills to critically evaluate AI-based clinical tools. This evidence-based approach demonstrates feasibility for integration into primary care professional development programs, addressing a critical gap in physician preparedness for AI-augmented practice.

ID 810- Acute focal bacterial nephritis in elderly patients

Rodica Sorina POP, Andreea Cristina MACOVEI, Aida PUIA

University Of Medicine And Pharmacy Iuliu Hatieganu, Cluj Napoca, Roumanie

Context: Psycho-emotional disorders are present in approximately one third of patients with heart failure (HF). When not adequately recognized, these conditions may lead to cardiac decompensation, the occurrence of acute coronary syndromes, reduced treatment adherence, and the relapse into or adoption of unhealthy lifestyle.

Objectives: The aim of this study was to identify the presence of anxiety and depression in patients with heart failure and to determine the factors associated with the development of psycho-emotional disorders in this population.

Methods: This observational study was conducted in five family medicine practices over a three-month period (January–March

2024). Adult patients with heart failure confirmed by a cardiologist were enrolled. Patients with a prior diagnosis of psychiatric disorders were excluded. Demographic data and information regarding the clinical stage of heart failure were collected. Anxiety and depression were assessed using the Hospital Anxiety and Depression Scale (HADS).

Results: The study sample included 103 participants, with a mean age of 71.17 ± 11.62 years. Clinical signs of depression were identified in 32.04% of patients, while anxiety symptoms were present in 26.21%. A statistically significant correlation was found between heart failure severity and anxiety and depression scores ($p = 0.007$ and $p = 0.009$, respectively). The number of family physician visits for heart failure related issues was significantly correlated with mean depression scores ($p = 0.003$), mean anxiety scores ($p = 0.001$), and heart failure severity ($p < 0.0001$). Factors associated with psycho-emotional disorders included older age ($p < 0.0001$), female sex ($p = 0.003$; $p = 0.002$), lower educational level ($p = 0.016$), and loneliness following the loss of a life partner ($p = 0.005$).

Discussion: A holistic approach to patients with heart failure requires the identification of risk factors for psycho-emotional disorders, their timely diagnosis, and appropriate referral for specialist care, alongside cardiovascular pharmacological treatment.

Conclusion: The family physician plays a crucial role in the objective identification of anxiety and depression in patients with heart failure. Routine heart failure follow-up consultations represent an important opportunity for the assessment of psycho-emotional disorders in cardiac patients.

ID 821- Acute Neurological Collapse in a Patient With Undisclosed Neurodegenerative Disease: A Case Highlighting the Importance of Accurate and Comprehensive Medical History in Primary Care

Mabrouk IMEN, Imen KETATA, Raja GALAI

Emargency Department Of Ibn Jazzar Kairouin, Monastir, Tunisie

Context: Scorpion envenomation is a major public health problem and a frequent reason for emergency consultation, particularly during the summer season. In Tunisia, the Primary Health Care Directorate (DSSB) reports approximately 30,000 scorpion stings per year, of which 1–2% evolve into severe forms.

Objectives: The objective of this study is to describe the epidemiological and clinical characteristics of scorpion envenomation cases managed in the Emergency Department of Ibn Jazzar Hospital in Kairouan.

Methods: This is a retrospective descriptive study involving 47 patients admitted to the emergency department for scorpion envenomation between May 1st, 2022 and September 31st, 2023.Inclusion criteria:Patients aged 18 years or older,Presenting to the emergency department for confirmed scorpion sting.Exclusion criteria:Patients presenting in cardiorespiratory arrest upon arrival.

Results: The study included 47 patients, with a slight male predominance:Men: 58%,Women: 42%.The median age was 40 years (IQR: 29–54 years).2. Circumstances of the Sting Place of sting:– Home environment: 70%.Seasonality:A clear peak in the hottest months, especially July and August.Location on the body:– Upper limbs: 42%– Lower limbs: 42%.Scorpion color:– Yellow scorpion: 58%.Use of traditional methods:– 94% of patients reported using traditional practices.Delay to consultation:– Median of 1 hour. Clinical Findings:Local signs were present in all patients (100%): redness, heat, swelling (each present in 94%).General symptoms were seen in 34%: asthenia (24%), chills (28%). Systemic Manifestations:Cardiovascular signs: 18%,Digestive signs: 32%.Vital Signs:Blood pressure: generally stable,Median heart rate: 88 bpm (IQR: 73–96),Median respiratory rate: 22/min (IQR: 20–24).Chest X-ray: normal in 20%,ECG: normal in 56%.Most patients showed favorable evolution, with rapid improvement.There was one reported death.

Discussion: This study provides an overview of the epidemiological and clinical characteristics of scorpion envenomation cases managed in the Emergency Department of Ibn Jazzar Hospital in Kairouan. Overall, the findings emphasize the need for continued public health interventions focusing on early consultation, avoidance of traditional harmful practices, and prevention strategies targeting households in endemic areas.

Conclusion: Scorpion envenomation is a frequent reason for emergency consultation, particularly during the hot season. Most patients arrived early to the emergency department, often after using traditional methods. In the majority of cases, clinical presentation remained limited to local signs and mild general symptoms, with rare severe complications.

ID 541- Acute visual symptoms after exercise: A possible retinal tear in a 33-year-old woman

Fariba YADOLAHI, Elmira HOSSEINI

Faculty Of Medicine, Zahedan University Of Medical Sciences, Zahedan, Iran (République islamique d')

Context: The prevalence of cardiovascular disease is intensely increasing particularly in developing countries. The burden of cardiometabolic disorders will increase in elderly.The southeast of Iran is bordering Afghanistan and Pakistan which suffers from the effects of low economic- social issues.

Objectives: The aim of this study was to investigate the prevalence of cardiometabolic disorders (diabetes, hypertension and hyperlipidemia) in older adults in the southeast of Iran.

Methods: This was a cross-sectional study. The study was conducted on 1952 older adults participating in (2023–2025|). Logistic regression models were used to determine the odds ratio and 95% confidence intervals (ORs and 95% CIs) of cardiometabolic disorders across related factors. Semi structured interviews performed to explore barriers to access health care system in this population.

Results: The mean age of the participants was 66.36 years. Scopes of diabetes, hypertension, hyperlipidemia and hypercholesterolemia were 531%, 78.91%, 63.84% and 41.31% respectively. Untreated diabetes prevalence was higher for males (OR = 1.80, 95%CI = 1.30–2.25), older adults (OR = 1.52, 95%CI = 1.03–1.08), and pre-frail status (OR = 0.68, 95%CI = 0.62–0.91). Males (OR = 2.26, 95%CI = 1.74–2.82) and current smokers (OR = 1.44, 95%CI = 1.15–1.93), in contrast to married participants (OR = 0.25, 95%CI = 0.08–0.78), people with higher education levels (OR = 0.51, 95%CI = 0.32–0.88) and dementia (OR = 0.81, 95%CI = 0.631–1.01) were more likely to have untreated HTN. Untreated dyslipidemia is more common in smokers (OR = 1.79, 95%CI = 1.18– 2.59) and males (OR = 1.57, 95%CI = 1.31–2.41), while untreated hypercholesteremia is more common in males (OR = 3.31, 95%CI = 1.63–6.59). Financial and insurance resources were the main barrier for participants to fully commit to a long-term health care or ongoing preventive program. There are no support structures for patients and the awareness of the disease is low.

Discussion: This study shows that gender and dementia are important factors affecting cardiometabolic disorders in elderly people living in south-east Iran.

Conclusion: The Iranian public health care (PHC) system and insurance companies need to target patients to improve their access to ongoing preventive program.

ID 1435- Addressing alcohol use in primary care: from screening to management - an interactive clinical decision workshop

Antonio Augusto FARIA CASTRO, Henrique CARVALHO GOES, Gabriela RODRIGUES GARCIA, Pedro DIRCEU ORTOLANI JÚNIOR, Paula PERCHES ORTOLANI

São Leopoldo Mandic Araras, Araras, Brésil

Context: Chronic Kidney Disease (CKD) is a common and progressive complication of Type 2 Diabetes Mellitus (T2DM), induced by sustained hyperglycemia that promotes glomerular injury, oxidative stress, inflammation, and activation of the renin-angiotensin-aldosterone system (RAAS). In this context, Sodium-Glucose Cotransporter 2 inhibitors (SGLT2i) demonstrate renoprotective effects by reducing intraglomerular pressure, whereas finerenone modulates renal inflammatory and fibrotic pathways via selective mineralocorticoid receptor antagonism.

Objectives: To evaluate the efficacy and safety of the combination of finerenone and SGLT2i in patients with CKD and T2DM.

Methods: A literature review was conducted in the PubMed database using the keywords 'Diabetes mellitus', 'Sodium-Glucose Cotransporter 2 Inhibitor', and 'Finerenone'. These descriptors were associated using the Boolean operator 'AND', and the search was filtered to clinical trials published in the last 5 years.

Results: Trials indicate finerenone reduces CKD progression and cardiovascular events, with a noted hyperkalemia risk. SGLT2 inhibitors (dapagliflozin and empagliflozin) demonstrate efficacy in reducing albuminuria and providing cardiorenal protection. The CONFIDENCE trial reported that combined therapy (finerenone plus empagliflozin) reduced the urine albumin-to-creatinine ratio (UACR) by 52% after 180 days. This reduction was numerically superior to monotherapy: 29% greater than finerenone alone and 32% greater than empagliflozin alone. Safety data showed the combination did not result in unexpected adverse events compared to individual agents.

Discussion: The combined regimen's superiority suggests synergy between SGLT2i hemodynamic effects and finerenone's anti-inflammatory/anti-fibrotic mechanisms. While finerenone carries a hyperkalemia risk, data suggests this is manageable and does not outweigh the significant reduction in albuminuria, a key surrogate marker for renal outcomes. The absence of unexpected adverse signals implies that maximizing cardiorenal blockade through this dual pathway is a safe strategy for high-risk patients.

Conclusion: The review of studies highlights benefits with both monotherapy and combined therapy of finerenone and SGLT2i in patients with CKD and T2DM. However, the combination of finerenone and SGLT2i presents superior clinical benefit in reducing albuminuria in this population, amplifying cardiorenal benefits without compromising safety. These findings reinforce the potential of combined therapy as a new therapeutic standard in diabetic nephropathy, and it should be considered in clinical practice and future guidelines.

(1) Unité De Recherche En Soins Primaires, Université Libre De Bruxelles, Bruxelles, Belgique
(2) University Of Glasgow, Glasgow, Royaume-Uni
(3) Primary Health Care Corporation, Doha, Qatar

Context: We are researchers and clinicians. Our research covers interdisciplinary topics aimed at improving primary care practices in the areas of access to care, social inequalities in health, health promotion, etc. We are aware that we are in a unique position, both as witnesses and actors in the realities on the ground. We also believe that we are sometimes led to form judgments based on our values, without always having the opportunity to go through the complete scientific process. We would like to propose an ethical reflection on this particular position of clinician and researcher. We will examine our feelings as individuals and the moral conflicts in which we find ourselves. We will feed our debate with the concepts of "positivism" and "constructivism." We will also analyse the historical construction of the notion of "neutrality" in medicine (whether in clinical care or academia). We take the position of addressing these questions at the beginning of our careers, based on the assumption that

these ethical considerations are shared by other clinician and researchers, both young and experienced.

Objectives: Have a collective brainstorming session on these ethical concepts that affect us all to varying degrees. Refine our position and strengthen our capacity for action.

Teaching method and workshop: We plan to discuss these topics in a forum of reflexion with collective intelligence facilitation tools and small groups discussions. - Introduction with a discussion of the concepts used (positivism, constructivism, neutrality) and examples of scientists

Expected outcomes: A collective and a personal reflection on the researcher's commitment to their subject of study.

Conclusion: We believe that WONCA is a place for debate, to strengthen our critical thinking skills and our position as clinicians and researchers.

ID 1119- Advance Care Planning in Neurocognitive Disorders: Challenges and Opportunities in French General Practice

Mabrouk IMEN, Imen KETATA, Ines DALI, Raja GLAI

Emargency Department Of Ibn Jazzar Kairouin, Monastir, Tunisie

Context: Emergency department work is recognized as one of the professions where the team is confronted with multiple and repeated stressful situations. We conducted an assessment of this topic with our emergency department team.

Objectives: The objective of our work was to determine the degree of stress among all members of the emergency department team and to identify the different stressors in order to modify them and improve the work environment.

Methods: This is a descriptive study conducted at the Ibn Jazzar Kairouan Emergency Department, involving 44 healthcare professionals. The study period was from November 2024 to January 31, 2025.We used the Karasake questionnaire.The responses to these questions are closed-ended, using a four-point . In practice, if the psychological demands score is above 20 and the decision latitude score is below 71, the employee is in the "strained" quadrant and therefore considered to be experiencing job strain.

Results: We included 44 participants. The participation rate was 86% for general practitioners . The majority of the population (34.9%) were between 45 and 49 years old. We noted a clear female predominance, with a sex ratio of 4.5. The sample study consisted of 37 general practitioners.The majority of participants (72.7%) reported working variable 24-hour shifts.A high prevalence of high psychological demands was noted among general practitioners and residents, with 65.1% of participants reporting a high level. The median psychological demands score was 29 points, indicating high psychological demands. Ninety-five percent of participants reported a medium to high decisional attitude. . Interpreting these different results placed our population within the "stressed" or job-strain category for the overall population.

Discussion: Overall, 60% of participants were classified as stressed, placing the majority of our study sample within the "job strain" quadrant of the Karasek model. These findings are consistent with literature indicating that women physicians often report higher stress levels due to a combination of professional and personal demands.

Conclusion: This study assesses the level of stress in the Ibn Jazzar Emergency Department. It was concluded that healthcare staff experienced significant stress, suggesting the need for improved working conditions and better organization of the healthcare structure.

ID 396- Advanced Gout in a Universal Healthcare System: The Impact of Rural Barriers to Care

Aysen KUTAN FENERCIOGLU

Department Of Family Medicine, Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Istanbul, Türkiye

Context: The context of this review article is the importance of vitamin D levels in chronic diseases with inflammation.

Objectives: This literature review aims to synthesize existing research on the anti-inflammatory roles of vitamin D (Vit D), elucidating its mechanisms of action, clinical implications, and potential therapeutic applications.

Methods: A standardized protocol was followed to perform a systematic literature review by a search of published articles in PubMed, Scopus, and Medline databases from their inception date until December 2024. A total of 59 published articles were reviewed for this study.

Results: Vitamin D receptors (VDRs) are present in almost all cells of the immune system, including B cells, T cells, NK (Natural Killer) cells, dendritic cells, and monocytes, as well as the epithelial cells of many organs such as the intestine, pancreas, prostate, lungs, and cardiomyocytes. In addition, some immune cells, including dendritic cells, macrophages, and B and T cells, can synthesize calcitriol by expressing 1α-hydroxylase. Upon binding to VDRs, vitamin D (Vit D) regulates the expression of genes involved in immune responses, including those encoding for cytokines. It modulates the production of pro-inflammatory cytokines while promoting the synthesis of anti-inflammatory cytokines. Vit D also affects the differentiation and maturation of cells of the immune system. By inhibiting the nuclear factor kappa B (NF-κB) and mitogen-activated protein kinase (MAPK) pathways, Vit D reduces the expression of pro-inflammatory genes.

Discussion: The evidence supporting the association between Vit D status and various inflammatory conditions is compelling, suggesting that maintaining adequate Vit D levels may be crucial for preventing and managing diseases characterized by chronic inflammation

Conclusion: These effects highlight the potential of Vit D as a therapeutic agent in the management of inflammatory diseases, including autoimmune disorders, cardiovascular diseases, diabetes, metabolic syndrome, cancer, neurological diseases, depression, and inflammatory bowel disease.

ID 2230- Advanced nursing practice indicators in Brazilian primary health care nursing consultations

Rumeysa KAYACAN, Eren YANIK, Ikbal Humay ARMAN

Department Of Family Medicine, School Of Medicine, Istanbul Medipol University, Istanbul

Context: Upper respiratory tract infections (URTIs) are a common reason for pediatric primary care visits and a major driver of antibiotic prescribing. Inappropriate antibiotic use contributes to antimicrobial resistance and remains a key quality-of-care challenge.

Objectives: To describe antibiotic prescribing patterns for pediatric URTI visits and examine variation by diagnosis category, age group, and season.

Methods: We are conducting a retrospective cross-sectional analysis of electronic health records from a pediatric outpatient clinic at a tertiary care centre. The study covers a one-year period and includes patients aged 0-18 years. Eligible encounters are identified using URTI-related ICD-10 codes recorded as the primary diagnosis. Outpatient visits with complete prescription data are included, while encounters requiring hospitalisation or involving diagnoses that typically require antibiotic therapy are excluded to ensure a clinically homogeneous sample. Primary outcomes include the proportion of URTI encounters resulting in an antibiotic prescription, the distribution of antibiotic classes, and prescribing rates stratified by age group, diagnosis category, and season. Descriptive statistics and chi-square tests will be used, with multivariable logistic regression planned as a secondary analysis. A minimum sample size of 400 eligible encounters is anticipated.

Results: Data extraction and dataset construction are underway. An interim analysis is planned prior to final submission, and full-period results will be presented at the conference. Results will include overall and diagnosis-specific antibiotic prescribing rates and seasonal variation. As a retrospective, single-center study based on routinely collected data, findings may be subject to diagnostic coding variability and incomplete documentation, which will be considered in interpretation.

Discussion: This study is expected to identify real-world patterns of antibiotic prescribing for pediatric URTIs and areas of potential overuse. Although conducted in a tertiary-care outpatient clinic, most URTI presentations are uncomplicated conditions commonly managed in primary care. The observed prescribing patterns are likely relevant to family physicians' clinical decision-making. Diagnosis-specific and seasonal variation may highlight opportunities for improved guideline adherence and targeted antimicrobial therapy in primary care.

Conclusion: This study will provide practical benchmarks for antibiotic prescribing in pediatric URTIs and support rational antibiotic use in family medicine. The findings may increase awareness of rational drug use and strengthen evidence-based practice in primary care.

(2) Clalit Healthcare Services And The Hebrew University, Jerusalem, Israël

Context: A case of a persistent fever in a 12 year old girl who consistently downplayed symptoms of a large labial minora abscess.

Methods: A 12 year old year presented to our clinic with a 5 day history of fever. She denied all symptoms apart from mild throat pain the previous day. Upon examination no obvious source of fever was found. The next day she reported mild dysuria. Bloods, serology and cultures were ordered. She was advised to start antibiotics for a urinary tract infection if symptoms continued over the weekend. She started the antibiotic treatment. However, the fever persisted despite the treatment and urine cultures subsequently yielded negative results; the antibiotics were stopped. Repeated history taking and examinations revealed no source. Initial serology results returned negative. Eventually, on day 10 the young patient confessed to her mother that she felt something on her vulva. With their consent the patient was examined and a large 3cm by 4cm abscess was found on her left labia minora. It appeared to have spontaneously drained. The next day the fever resolved. The patient was referred to gynaecology. She received the appropriate treatment including antibiotics.

Originality: This case was increasingly looking to be an FUO case . Steps were taken to investigate the cause methodically. The source was eventually found to be a large labia minora abscess. An uncommon finding in itself, but also it was alarming to us that the child felt unable to report the abscess until day 10, especially given its size.

Lessons learned and future implications: It was a perfect case for how to methodically work through a persistent fever of unknown source. It was also a reminder that paediatric patients may struggle to report certain complaints.

Discussion: The medical profession appreciates that abdominal pain in young boys could mean testicular pain. This case shows that "mild dysuria" or "discomfort" in young girls might be disguising an uncommon vaginal complaint such as an abscess.

Conclusion: A broad mindset is always required when approaching a case of suspected FUO. This case proves that a broader once still is required when dealing with pediatric cases.

ID 599- Advancing liberty, equity and fraternity: practical solutions for European primary care (Workshop 2)

Eren YANIK, Rumeysa KAYACAN, Ikbal Humay ARMAN

Department Of Family Medicine, School Of Medicine, Istanbul Medipol University, Istanbul, Türkiye

Context: Functional gastrointestinal symptoms consistent with irritable bowel syndrome (IBS) are common during adolescence and frequently present to primary care, with potential impacts on school attendance, health care utilization, and quality of life. Primary care plays a key role in the early recognition and appropriate management of these symptoms.

Objectives: To estimate the frequency of Rome based IBS symptom patterns among adolescents presenting to primary care and to describe associated symptom burden and health care seeking characteristics.

Methods: We are conducting an ongoing cross-sectional survey across multiple family health centres in Istanbul, Türkiye. Adolescents aged 8 to 17 years attending primary care for any reason are screened using a brief Rome based symptom questionnaire. The selected age range aligns with commonly used pediatric IBS epidemiological frameworks and supports reliable self-reporting. Participants reporting alarm features or known organic gastrointestinal conditions are excluded to focus on functional symptom patterns relevant to primary care. Additional questionnaire items assess symptom burden and patterns of health-care use. Descriptive statistics will be used to estimate symptom frequency and burden, with exploratory group comparisons performed using chi-square tests. A minimum target sample size of 300 adolescents is planned and considered feasible within routine primary care recruitment.

Results: The questionnaire has been developed and piloted to assess feasibility, comprehension, and completion time. Participant recruitment is ongoing, and results will be presented at the conference. As a symptom based cross-sectional survey relying on self-reported data, findings may be influenced by recall bias and by the inability to establish a formal IBS diagnosis. These limitations will be considered when interpreting the results.

Discussion: Estimating the frequency and burden of Rome consistent IBS symptom patterns in primary care highlights the clinical relevance of functional gastrointestinal symptoms among adolescents and points to the need for structured recognition in routine practice.

Conclusion: Primary care based assessment of Rome consistent IBS symptoms may facilitate timely recognition and patient centred management of functional gastrointestinal symptoms in adolescents.

Context: Social media shapes how the public and health professionals access, share, and judge health information. Nursing digital influencers may strengthen health literacy and trust in primary care by disseminating evidence-informed content and correcting misinformation, yet their profiles and audience motivations are not well described.

Objectives: To characterize nursing digital influencers and analyze audience connection justifications related to dissemination of health information and confrontation of misinformation.

Methods: Documental, cross-sectional quanti-qualitative study using public data from

Instagram, Facebook, TikTok, X (formerly Twitter), and YouTube (July 2022 to December 2024). Eligible accounts were public profiles of nursing professionals identified as opinion leaders using the Flynn, Goldsmith and Eastman model, with professional status verified in the national registry; only profiles created before the COVID-19 pandemic were included. Variables (platform, follower volume, profile type, professional category, main theme) were summarized with frequencies; chi-square tests for trend used alpha=0.05. Connection-justification texts were analyzed in IRaMuTeQ (text analysis software) (similarity analysis with chi-square and Z-scores for word prominence).

Results: We identified 324 nursing digital influencers with a combined reach above 45 million followers. Most were registered nurses (91.4%), managed personal profiles (75.4%), and used Instagram (75.3%) ($p<0.05$ for trends). Nursing education was the most frequent main theme (31.2%), followed by general nursing (24.7%). Most total audience reach was concentrated among macro-influencers (500,000 to 1,000,000 followers). Two thematic domains emerged from connection justifications. Dissemination of health and nursing information included engagement with educational content, professional development, technical-practical guidance, and appreciation. Confronting misinformation included professional advocacy and identity, daily practice experiences, critique of devaluation and power, peer support, and legitimizing the influencer as a spokesperson. A central lexical cluster connected learning and professional interest to nursing identity and advocacy.

Discussion: The combination of high reach, educational focus, and explicit misinformation correction suggests that nursing influencers are relevant actors for primary care oriented health communication. Their legitimacy also underscores the need for ethical guidance and quality assurance for online health information.

Conclusion: Nursing digital influencers can contribute to dissemination of reliable information and to confronting health misinformation. Collaborative strategies with primary care services and professional bodies may enhance health literacy and trust.

ID 2022- AF and GP

Agathe STOESSEL

Sorbonne Université, Paris, France

Context: Food insecurity, defined as insufficient access to adequate quality or quantity of food, is an increasing public health concern. University students are particularly vulnerable, and this situation is associated with poorer health and academic outcomes. However, few studies have focused on medical students, whose training involves unique academic and personal challenges.

Objectives: The primary objective was to estimate the prevalence of food insecurity among medical students enrolled in the second cycle of medical studies. The secondary objective was to identify associated factors.

Methods: We conducted a multicentre cross-sectional study from April to August 2023, with an online questionnaire, among medical students in XXX enrolled in their 4th to 6th year of medical studies. Participants were recruited via two channels: direct email invitations sent to eligible student cohorts and dissemination of the survey link on social networks. Food insecurity was assessed using the 10-item USDA Household Food Security Survey Module (HFSSM). Descriptive and bivariate analyses were performed to explore associated factors.

Results: A total of 609 students participated. The study population included 75% women and 27% scholarship holders, with participants from five universities. This represented approximately 11% of the target population and was consistent with the demographic distribution usually reported in this group. The prevalence of food insecurity was 18.2% (95% CI 15.2–21.3). It was significantly higher among students receiving scholarships, those working alongside their studies, those living in student housing, and those with chronic illnesses or self-perceived poor health.

Discussion: This study provides the first XXX estimate of food insecurity among medical students using a validated scale. The large sample size strengthens its reliability, though selection and participation biases cannot be excluded. The prevalence observed is higher than in the general population and consistent with international literature linking food insecurity to economic and health vulnerabilities.

Conclusion: Food insecurity affects a substantial proportion of future physicians and may impact both well-being and academic performance. Addressing this issue is relevant to medical education and general practice, as it highlights the role of socioeconomic factors in health. Further nationwide studies should explore causal pathways and guide interventions to support medical students and enhance equity in healthcare training.

(5) Department Of Family Medicine, Kütahya Health Sciences University, Kütahya, Türkiye

Context: Ethical decision-making in primary care often occurs in “grey zones” where clinical guidelines offer limited guidance and competing values must be balanced. Family physicians routinely face ethical dilemmas embedded in everyday consultations, such as responding to non-medical requests for reports or prescriptions, managing repeated somatic complaints driven by psychosocial distress, or balancing patient autonomy with professional responsibility in relationships. These situations are rarely dramatic, yet they significantly influence clinical quality, professional integrity, and patient trust. Such dilemmas are highly context-dependent and shaped by cultural norms, healthcare systems, and the continuity of doctor–patient relationships. In international settings like WONCA, similar ethical challenges may be interpreted and managed differently. This workshop creates a structured, reflective space for participants to explore how ethical reasoning operates in real-life primary care encounters across diverse contexts.

Objectives: By the end of the workshop, participants will be able to: 1.Identify common, everyday ethical dilemmas specific to primary care practice. 2.Analyse these dilemmas using core ethical principles (autonomy, beneficence, non-maleficence, justice). 3.Reflect on and compare different culturally and system-informed approaches to managing ethical uncertainty in primary care.

Teaching method and workshop: The workshop uses interactive, case-based learning primary care scenarios. Participants will work in small, facilitated groups to discuss anonymised cases reflecting ethical grey zones, including non-medical requests, psychosocially driven presentations,

Expected outcomes: Participants will gain practical frameworks for ethical reflection, increased confidence in navigating uncertainty, and transferable insights applicable to daily primary care practice.

Conclusion: By focusing on everyday ethical grey zones, this workshop strengthens family physicians’ ethical reasoning in routine practice. Through case-based discussion and international peer exchange, participants gain practical strategies to manage uncertainty, set professional boundaries, and maintain patient trust, supporting ethically grounded and person-centred primary care across diverse contexts.

ID 2216- AI Literacy for Family physicians (ALF): development and evaluation of artificial intelligence training for family physicians

Mete SIMSEK, Ikbal Humay ARMAN

Department Of Family Medicine, School Of Medicine, Istanbul Medipol University, Istanbul, Türkiye

Context: Burnout among family physicians is a significant and increasingly recognised issue that affects physician well-being and the quality of patient care. While its associations with job dissatisfaction and medical errors have been widely reported, its potential impact on patients' perceptions of psychosocial support remains less explored. In primary care, psychosocial support is a central component of patient-centred and holistic practice.

Objectives: To examine the relationship between burnout levels among family physicians and patients' perceptions of psychosocial support in primary care settings.

Methods: A cross-sectional mixed-methods study is planned in three major regions of Istanbul. Thirty family physicians will be included. Burnout will be assessed using the Maslach Burnout Inventory (MBI). For each physician, ten adult patients will complete the Patient–Doctor Relationship Questionnaire (PDRQ-9) following a routine consultation. Patients will also respond to semi-structured open-ended questions exploring perceived psychosocial support, communication, and emotional engagement during the consultation. Quantitative data will be analysed using descriptive statistics and Spearman correlation analyses between MBI subscale scores and physician-level mean PDRQ-9 scores. Qualitative data will be analysed thematically to complement quantitative findings.

Results: A negative association is anticipated between physician burnout and patient-perceived psychosocial support. Higher levels of emotional exhaustion and depersonalisation are expected to be associated with lower PDRQ-9 scores. Thematic analysis is anticipated to identify patient-reported perceptions related to emotional connection, communication quality, and engagement during consultations.

Discussion: The integration of quantitative and qualitative findings is expected to provide a more comprehensive understanding of how physician burnout may influence psychosocial aspects of the doctor–patient relationship from the patient perspective.

Conclusion: Exploring the relationship between family physicians' burnout and patient-perceived psychosocial support may contribute to evidence-informed approaches aimed at supporting physician well-being and enhancing the psychosocial quality of primary care.

Mabrouk IMEN, Imen KETATA, Raja GALAI, Ines DALI

Emergency Department Of Ibn Jazzar Kairouin, Monastir, Tunisie

Context: Community-acquired pneumonia (CAP) is a major public health problem and remains one of the leading causes of morbidity and mortality related to infectious diseases. It is also among the most common reasons for consultation in emergency departments.

Objectives: This study aims to describe the epidemiological, clinical, paraclinical, therapeutic, and evolutionary characteristics of patients managed for CAP in the emergency department of Ibn Jazzar Hospital in Kairouan, and to evaluate hospitalization and orientation strategies.

Methods: This was a retrospective observational study conducted from September 2023 to December 2024 in the emergency department of Ibn Jazzar Hospital, including all patients diagnosed with CAP during the study period.• Inclusion criteria:All adult patients aged 18 years or older admitted for CAP . Exclusion criteria: Patients with incomplete records, those with nosocomial

pneumonia, or those who refused to participate in the study.

Results: Thirty patients were included: 15 men (50%) and 15 women (50%), sex ratio = 1. Mean age: 64.7 ± 17.6 years (range 17–98). Patients over 60 years accounted for 73.3%. COMORBIDITIES AND RISK FACTORS:Comorbidities were present in 60% of patients: – Chronic respiratory disease (40%) ,– Diabetes (30%) ,– Hypertension (23.3%) ;Smoking: 40%.CLINICAL FEATURES:Most frequent symptoms: – Cough: 80% ,– Dyspnea: 70% ,– Fever: 56.7% .Vital signs: – Temperature: (fever in 40%) ;– Heart rate: 87 bpm (tachycardia in 23.3%) ;– Respiratory rate: 27.5 cycles/min ;– SpO_2: 84.8% (<94% in 76.6%) ;– Respiratory distress: 56.7% .PARACLINICAL DATA:– Chest X-ray: • Pulmonary consolidation: 30% ; • Interstitial syndrome: 26.7% . MANAGEMENT:Oxygen therapy required in 73.3% of cases;.Antibiotic therapy: – Monotherapy (amoxicillin-clavulanic acid): 50% ; – Dual therapy (cefotaxime + levofloxacin): 50%.CLINICAL EVOLUTION (CRB-65):Group 1 (score 0–1): 10 pts → no deaths ;Group 2 (score 2): 15 pts → 4 stable, 2 worsened, 1 death ;Group 3 (score ≥3): 3 stable, 1 death.

Discussion: Our study highlights epidemiological and clinical characteristics consistent with international data. The CRB-65 score proved effective in stratifying severity and guiding hospitalization decisions.

Conclusion: CAP remains a common and potentially severe condition. Early evaluation, severity assessment using tools like CRB-65. Strengthening diagnostic and therapeutic resources is necessary for optimized emergency care.

ID 2056- AI-Assisted diagnosis in general practice: impact on clinical decision-making

Ekin DIKMEN [(1)] , Ezekie C ERNEST [(2)], Olaniran OYEYEMI [(2)], Sena AKYAR [(1)]

(1) Trakya University, School Of Medicine, Family Medicine Department, Edirne, Türkiye

(2) Howard University Hospital, Department Of Family And Community Medicine, Washington,dc, États-Unis

Context: Family physicians are de facto leaders of their clinics, yet formal leadership training is often lacking. The WONCA Europe 2026 theme; Liberty (autonomy), Equity (fairness), and Fraternity (team cohesion) mirrors the core tensions in clinical management. Physicians must balance these values against the harsh realities of primary care, deciding when to empower the team (Liberty), how to serve needs fairly (Equity), and how to build consensus (Fraternity), versus when to take absolute command during a crisis.

Objectives: 1. Participants will identify their own dominant leadership style (Authoritative, Democratic, Servant, or Delegating) using a rapid, vignette-based assessment tool. 2. Participants will apply their specific leadership style to solve a complex ''Monday Morning Crisis'' scenario in a primary care setting. 3. Participants will evaluate the strengths and blind spots of each style to develop a "hybrid" leadership toolkit for future practice.

Teaching method and workshop: This is a highly interactive, gamified session using a ‘’Scenario-Based Learning’’ approach. 1. ‘’The Leadership Compass’’: A 5-question rapid quiz based on Lewin and Greenleaf’s theories divides participants into four ‘’Tribes’’ (Commanders, Diplomats, C

Expected outcomes: Participants will gain a clear ‘’diagnostic map’’ of their natural leadership reflexes (e.g., Commander vs. Caretaker). They will acquire practical strategies to toggle between styles using authority to manage crises, delegation to foster Liberty, and emp

Conclusion: We conclude that leadership in family medicine is the art of balancing tensions. Participants will leave with a practical roadmap to navigate these dynamics, ensuring that their leadership style does not just dictate, but serves protecting the Liberty of their team to innovate, ensuring Equity in workload distribution and strengthening the Fraternity essential for surviving the daily challenges of primary care.

ID 233- AI-Assisted Implementation of an Integrated Deprescribing and Medication Optimization Flowchart for Home Care Patients with Polypharmacy

Rumeysa KAYACAN, Eren YANIK, Ikbal Humay ARMAN

Department Of Family Medicine, School Of Medicine, Istanbul Medipol University, Istanbul, Türkiye

Context: Asthma is a common chronic disease in childhood, and achieving optimal symptom control remains challenging. Lifestyle-related factors, including dietary patterns such as the Mediterranean diet, may influence asthma outcomes through anti-inflammatory and antioxidant effects.

Objectives: To systematically review the evidence on the association between postnatal adherence to the Mediterranean diet and asthma control and exacerbations in children and adolescents.

Methods: A systematic literature search was conducted in PubMed to identify studies published between 2007-2024 evaluating Mediterranean diet adherence and asthma-related outcomes in individuals aged 0-18 years. Eligible studies used validated Mediterranean diet indices (e.g., Mediterranean Diet Score, KIDMED) and reported asthma control, wheezing, or exacerbation outcomes. Prenatal exposure studies and adult populations were excluded. The methodological quality of included observational studies was assessed using the Newcastle–Ottawa Scale (NOS) and considered in the interpretation of findings. Reported adjusted odds ratios and corresponding confidence intervals were collated and synthesized to support comparative presentation of results.

Results: A total of six pediatric studies, including population-based cross-sectional studies and a limited number of prospective or intervention studies from Europe, Latin America, and the Middle East, were included. Higher adherence to the Mediterranean diet was associated with improved asthma-related outcomes, with reduced odds of wheezing or asthma symptoms (adjusted odds ratios ranging from 0.45 to 0.70 (95% CI: 0.28-0.90). Incremental increases in Mediterranean diet scores were linked to a modest reduction in severe asthma or frequent wheezing. Evidence on asthma exacerbations was limited and heterogeneous, as objective outcomes were infrequently reported.

Discussion: Greater adherence to the Mediterranean diet is associated with better asthma control and fewer respiratory symptoms in children, while evidence for a reduction in asthma exacerbations remains inconclusive.

Conclusion: From a primary care perspective, promoting healthy dietary patterns may represent a feasible, low-risk, non-pharmacological approach to support pediatric asthma management. Further prospective studies and randomized controlled trials are needed.

ID 66- AI-Driven Simulation for Better Urgent Care Decisions

Camila Cristina DE OLIVEIRA RODRIGUES, Maria Eduarda RODRIGUES CAETANO

Faculdade São Leopoldo Mandic Araras, Araras, Brésil

Context: Brazil´s Unified Health System (SUS) organizes Primary Health Care (PHC) through the Family Health Strategy (FHS), its main territorial model. Community Health Workers (CHWs) playing a pivotal role in direct engagement within communities. Their activities include home visits, vulnerability assessment, and family follow-up, fostering continuity of care. This proximity positions CHWs as key actors in the early detection of health risks, including those related to alcohol and drug use. SUS adopts harm reduction as a guiding principle, aligned with human rights. Understanding CHW´s responsibilities and challenges is essential to strengthen prevention and person-centered care strategies in PHC.

Objectives: To analyze and synthesize evidence on the role of Community Health Workers in

the early identification of health problems related to alcohol and other drug use, potentialities, barriers, and strategies to improve CHW performance in Primary Health Care.

Methods: A narrative review was conducted, including institutional documents and qualitative studies on harm reduction, practices and professional performance within the Family Health Strategy. Materials addressing CHW work, harm reduction policies, and the management of drug-related problems were included. The analysis emphasized convergent themes, considering the predominance of qualitative approaches and their implications for practice.

Results: The reviewed studies indicate that CHWs occupy a strategic position in the early identification of drug-related health problems due to their close relationship with families, regular home visits, and knowledge of the territory. Despite this, actions remain limited and are frequently restricted to referrals. Barriers include stigma, moralistic views, work overload, lack of matrix support, and insufficient continuing education.

Discussion: This review highlights the significant potential of CHWs to support prevention and care related to drug use; however, this potential is constrained by structural and subjective barriers. These challenges reflect systemic gaps in training, support, and integration with specialized services, which hinder the implementation of harm reduction principles.

Conclusion: This review highlights the significant potential of CHWs to support prevention and care related to drug use; however, this potential is constrained by structural and subjective barriers. These challenges reflect systemic gaps in training, support, and integration with specialized services, which hinder the implementation of harm reduction principles.

(2) São Camilo University Center, School Of Medicine, São Paulo, Brésil

Context: Understanding how people navigate services is essential for family medicine and primary care. In Brazil, the Unified Health System (SUS) is organized through Health Care Networks (Redes de Atenção à Saúde, RAS). Undergraduate teaching often presents the RAS concept with limited contact with real referral pathways.

Methods: This practice based reflection synthesizes technical visits carried out in 2024 and in the first semester of 2025 in a Collective Health module for fifth semester medical students. Each semester, 90 students were enrolled. Small groups visited one RAS service under faculty supervision and used a shared observation guide focused on first contact and reception, access, comprehensiveness, interprofessional work, and network articulation. Sites included Basic Health Units (Unidades Básicas de Saúde, UBS), which function as primary health care (PHC) clinics, Psychosocial Care Centers, a reference unit for older people's health, a specialized rehabilitation center, general hospitals, and specialty outpatient clinics.

Originality: The design converts single site visits into a network level understanding through standardized observation and collective synthesis across groups.

Lessons learned and future implications: Students linked user needs to service functions, identified barriers in access and coordination, and discussed feasible improvements for referrals and counter referrals. Future editions can add brief pre and post questionnaires, expand to other thematic networks, and

incorporate extension activities based on needs observed in services.

Discussion: Immersion in the RAS supported competencies relevant to integrated care, including communication, interprofessional collaboration, feasible referral planning, and critical reflection on equity and continuity of care.

Conclusion: Short technical visits, combined with structured guidance and collective synthesis, can strengthen undergraduate medical education oriented to coordinated care within the SUS.

(1) University Of Health Sciences Izmir Faculty Of Medicine, Department Of Family Medicine, Tepecik Training And Research Hospital, Izmir, Türkiye
(2) University Of Health Sciences,tepecik Training And Research Hospital, Izmir, Türkiye

Context: It is evident that the COVID-19 pandemic has affected all segments of society in many ways since its declaration.

Objectives: In this study, it was aimed to evaluate whether there is a change in the level of smoking and nicotine addiction of family medicine specialty students who encountered various risk factors in their working environment during the COVID-19 pandemic and to evaluate the related factors.

Methods: In the research, an online questionnaire was applied to family medicine specialty students working throughout the province of Izmir between 01/04/2023 and 31/05/2023. 201 of the 405 people reached in total agreed to participate in the study and completed the questionnaires. In the first part of the questionnaire, questions were asked about sociodemographic information, workplaces during the COVID-19 pandemic and smoking behaviors. The second part included the Fagerström Nicotine Dependence Test.

Results: The mean age of 201 participants who participated in the study was 29.6±3.6 (min: 23, max: 51), 65.7% were female. The number of participants actively working in at least one place during the COVID19 pandemic was 91.5% and 29.4% smokers. 5.0% of the participants increased smoking during the pandemic. To the question of what will be your smoking status if the COVID-19 pandemic process is repeated, 8 participants (4.0%) said “I smoke, I can increase it”, 31 participants said (15.4%) “I smoke, my count does not change” and 13 participants said (6.5%) “ I smoke, I can quit”. The FNBT scores of the participants who did not have COVID19 infection were statistically higher than those who had COVID-19 infection (p=0.023).

Discussion: Approximately 30% of family medicine specialty students that they smoked during the COVID-19 pandemic. Although the risks in the pandemic process are known, there has not been an expected decrease in smoking behavior, but a slight increase has been detected. The factors affecting this situation should be carefully evaluated.

Conclusion: Smoking cessation activities should be individualized and necessary psycho-social support should be provided. Studies that give importance to the wellbeing of physicians, who guide the society and are also a part of the society, should be increased in order for the society to adopt healthy lifestyles.

Manoel MIRANDA NETO [(1)], Renata Laszlo TORRES [(2)] , Mariana Almeida ROCHA [(2)], Cíntia Leci RODRIGUES [(2)], Marcela Maria PANDOLFI [(2)], Renata Holanda Dos Anjos LIMA [(2)], Douglas Pereira De SOUZA [(2)], Fernanda Tavares De Mello ABDALLA [(2)]

(1) School Of Nursing, University Of São Paulo, São Paulo, Brésil
(2) São Camilo University Center, School Of Medicine, São Paulo, Brésil

Context: Medical training that immerses students in primary health care (PHC) can strengthen competencies for person centred and equitable care. Ageism refers to stereotypes, prejudice, and discrimination based on age. It undermines older people’s access to services, the quality of care, and

autonomy, yet it remains insufficiently addressed in undergraduate curricula.

Methods: We report a curricular extension activity implemented in the first semester of 2025, with 90 medical students enrolled. Supervised by faculty, the activity took place in Brazilian primary health care (PHC) clinics (Basic Health Units) within the Unified Health System (SUS) in an urban setting. Students co-created a plain-language leaflet on ageism, older people's rights, common health needs and how to navigate local care networks. The intervention was delivered in UBS waiting rooms through brief conversation circles that combined welcoming, active listening, guided questions and practical orientation about access to services and resources. Faculty facilitated debriefing and reflection to connect community needs, communication skills and equity-oriented practice.

Originality: This experience uses the waiting room as a pedagogical and citizenship space and places ageism and rights at the centre of a PHC health education device. It integrates teaching, service and community engagement while promoting intergenerational dialogue and addressing a neglected form of stigma that is relevant to everyday general practice.

Lessons learned and future implications: Accessible language facilitated engagement and understanding; horizontal dialogue and qualified listening helped identify misconceptions and barriers to service navigation; student co-authorship increased ownership and motivation. The activity proved feasible within PHC routines, but highlighted the need for systematic formative evaluation (e.g., brief pre/post questions), adaptations for sensory and literacy needs, and strengthened intersectoral partnerships to sustain and expand actions across successive student cohorts.

Discussion: Embedding anti-ageism content in PHC-based education aligns with humanism and equity, supports health literacy, and may improve communication and trust between services and older users.

Conclusion: A waiting-room, student-led extension strategy is a feasible approach to integrate anti-ageism and rights-based education into PHC teaching. Future iterations should incorporate simple outcome measures and accessibility enhancements to strengthen transferability to other PHC settings.

ID 1400- All of a sudden, sitting across the table in my practice, he pulled out his gun

Abdelkader LAHMAR, Amélie GENG

University Of Strasbourg, Strasbourg, France

Context: The increasing digitisation of healthcare is transforming patients' access to information and services. In France, 51% of the population used the internet for health-related purposes in 2022. Although information and communication technologies (ICT) are often promoted as tools for patient empowerment and healthcare system improvement, little is known about how patients actually use them, the determinants of these uses, and their implications for primary care.

Objectives: The primary objective of this study was to explore patients' perspectives on their uses of ICT for health. We aimed to develop a typology of uses, identify their determinants, and analyse patients' perceptions of their impact on care and the patient–doctor relationship in primary care.

Methods: We conducted a qualitative, non-interventional study between February and May 2023 in Alsace, France. Using iterative theoretically reasoned sampling, six adult patients followed in primary care and using ICT for health-related purposes were recruited. Data were collected through semi-structured interviews. A hybrid deductive–inductive qualitative content analysis was performed, informed by Mastafari's ICT typology. A total of 585 coded segments were analysed.

Results: Four categories of ICT use were identified: ICT for training and self-directed learning; ICT for research and documentation; ICT for exchange, communication, collaboration, and cooperation; and ICT for organisation and management. No use related to producing, creating, or publishing content

was reported. Determinants of use included patients' perceptions of health, trust in digital information, and facilitating or inhibiting factors such as digital skills, access, usability, and perceived added value. Patients reported ambivalent perceptions, combining feelings of autonomy, reassurance, and empowerment with anxiety, information overload, and concerns regarding professional legitimacy. Across all categories, hidden inequalities in access, skills, and awareness were identified.

Discussion: Patients' ICT use reshapes roles and expectations in primary care, fostering engagement while also generating new tensions and reinforcing digital and social inequalities. Patients are not always aware of the broader individual and systemic implications of their digital practices.

Conclusion: Patients' uses of ICT in healthcare reveal hidden inequalities and contribute to transforming the patient–doctor relationship. These findings highlight the need for primary care professionals to support equitable, informed, and shared digital health practices.

(1) Faculté De Santé, Terre-Sainte, Réunion
(2) Faculté De Santé - Terre-Sainte (Réunion), Boueni, Mayotte

Context: Endocrine disruptors represent an emerging risk to human health. The perceived lack of knowledge, contradictory research findings, and the absence of official recommendations hinder the dissemination of information to patients. The perinatal period constitutes a phase of significant vulnerability; however, parents' knowledge regarding these risks remains limited

Objectives: The objective of this study was to gather information on parents' experiences with these risks and their specific expectations.

Methods: A qualitative, phenomenological study was conducted through open-ended individual interviews between June 2023 and February 2024, until data saturation was reached.

Results: Controversies surrounding healthy lifestyles abound, and current practices are not always appropriate. Parental responsibilities often lead to learning from media sources, which are frequently questionable. For greater reliability and independence, there needs to be less medical discretion and more efforts to combat misinformation, disinformation, and conflicts of interest. Information dissemination must be tailored to individual needs, and free will must be respected, as many obstacles to change exist.

Discussion: The lack of pre-existing studies and the recent emergence of endocrine disruptors in the news make this work unique. Despite likely biases in self-reporting, selection, and interpretation (lack of data triangulation), this study is consistent with the existing literature. Endocrine disruptors remain poorly understood but are intuitively perceived by parents. Access to reliable, supportive, and unbiased information is sought. Research on other populations or in other areas of environmental health would be beneficial. It would also be relevant to study how patients use digital tools—the internet, social media, artificial intelligence—in their information searches and knowledge construction.

Conclusion: This study, conducted in La Réunion, is innovative and consistent with the literature. Endocrine disruptors are still relatively unknown, but parents are intuitively aware of them. Access to reliable, benevolent and unbiased information is essential. Researching other populations or areas of environmental health would be useful.

ID 82- Allergic Reaction to Tranexamic Acid: A Therapeutic Dilemma in a Patient with von Willebrand Disease

Tiago ALMENDRA [(1)] , Sofia COSTA [(1)], Alberto GALÁN [(2)]

(1) Ucsp Albufeira, Albufeira, Portugal
(2) Centric Health, Ireland, Espagne

Context: Lower-limb musculoskeletal complaints are a frequent reason for consultation in primary care and often present diagnostic challenges. Clinical examination alone may not reliably differentiate muscle injury, joint effusion and tendon pathology. Point-of-care ultrasound (PoCUS) provides a safe and radiation-free extension of the physical examination, improving diagnostic accuracy and supporting timely clinical decision-making. However, access to practical PoCUS training tailored to the needs of family medicine remains limited. This workshop aims to address this educational gap by focusing on essential ultrasound concepts and key anatomical landmarks for the assessment of the knee and the calf–Achilles complex in primary care.

Objectives: Participants will be able to: - Recognise normal sonoanatomy of key lower-limb structures relevant to primary care; - Perform a focused knee ultrasound to assess joint effusion and periarticular tendons; - Acquire standard ultrasound views of the gastrocnemius–soleus complex and Achilles tendon; - Recognise common pathological patterns, including muscle tears, joint effusion and tendinopathy.

Teaching method and workshop: The workshop will use a structured, case-based approach. Participants will discuss clinical cases integrating symptoms, physical examination and ultrasound findings to support diagnostic reasoning. Teaching will be supported by the presentation of selecte

Expected outcomes: Participants will gain clear, practical landmarks and high-yield tips for lower-limb ultrasound assessment, improving diagnostic confidence and facilitating integration of PoCUS into everyday primary care consultations.

Conclusion: This workshop provides a concise and clinically focused introduction to lower-limb ultrasound for family physicians, emphasising essential landmarks and practical skills to enhance patient assessment and management in primary care settings.

ID 2129- Ambient Voice Technology to Improve Documentation and Clinician Wellbeing in Primary Care

Natalia ALMENDROS VÍLCHEZ, Belén VÁZQUEZ MARÍN, M Lorena ARAGÓN GUILLÉN

Servicio Andaluz De Salud, Marbella, Espagne

Context: 42-year-old female patient who goes to the Primary Care Consultation. She reports that 1 month ago has had blurred, sometimes accompanied or not by holocranial headache, sometimes pungent with a duration more or less 15 minutes that gives away with paracetamol. The patient, a Family Doctor, associates it with greater stress due to the care burden at work, so she didn´t worry till was more frecuently.

Methods: No allergies, no toxic habits. 3 pregnancies, last with Gestational Diabetes with prediabetes currently with recent treatment with metformin. Hypothyroidism after Hashimoto´s T with levothyroxine. Also she used topical retinol 5 days/week. BP 100/70. BMI 29. Neuro: Conscious and oriented. Language without alterations. normal cranial pairs, no dysmetry, no adidocokinesia, no Romberg, symmetric Rot not exalted. Dubious tandem. She was referred to the Emergency Service for evaluation by Ophthalmology and Internal Medicine: Posterior Pole described both eyes with loss od papillary profile confirmed with OCT a bilateral increase in thickness and Campimetry with increase in Blind Spot. Cranial CT scan and MRI without significant findings. Analytical without alterations even vitamin A in normal range. Lumbar puncturre LCR with output pressure 50mmHg, transparent with negative culture. Treatment was initiated with acetazolamida 6cp per day and potassium before the diagnosis of " Benign Idiopathic Intracranial Hype.rtension" After 9 months of oral treatment, she was referred to Neurosurgery with new tests. A venous MRI angio where it observed a bilateral transverse breast stenosis (right 3.5 cm and 2.5 cm left being hypoplastic). Endovascular treatmentof right breast stenosis was decided after checking a pre/post stenosis pressure gradient of 10 mmHg with improvement of it after the procedure. Doble

antiaggregation began for 3 months, maintaining acetylsalicylic 300mg.

Originality: Special case where it is highlighted how from Primary Care we can make a temporary follow- up of the patient, seeing the evolution of the symptoms, emphasizing changes in lifestyle, prevention of FRCV as well as taking care of the mental health of patients.

Lessons learned and future implications: Do not underestimate any symptoms and or signs that patients may give us.

Discussion: As a complicated case, it can be addressed from Primary Care and be conducted and accompaied throughout the process, always having a comprehensive focus on the patient.

Conclusion: In summary, maintaining a good doctor-patient relationship, maintained over time,we see interesting cases for our daily practice. It is an example ot the meaning of our profession, so punished with burnt out, but that we try to take care of everyone for good health.

ID 2296- Ambulatory primary care production and early medical training in Brazil: a time-series analysis, 2008–2024

Ahryoung KO, Ju Hyun KANG, Sang Min PARK

Seoul National University Of Hospital, Seoul, Corée (République de)

Context: By integrating Metabolic Equivalent of Task (MET) values and frequency to assess PA, alongside Medication Possession Ratio (MPR) for antidepressant adherence, this study sought to provide a more comprehensive and clinically grounded evaluation.

Objectives: Depression is a known risk factor for dementia, and physical activity (PA) benefits both conditions. This study examined whether early physical activity after a new depression diagnosis is associated with subsequent dementia risk.

Methods: This cohort study used data from the Korean National Health Insurance Service and included 46,871 patients with newly diagnosed depression. PA within two years of diagnosis was categorized by frequency (0, 1-2, 3-4, ≥5 times/week) and by metabolic equivalent of task (MET) levels (0, 1–499, 500–999, ≥1000 MET-min/week). Cox proportional hazards models were used to estimate adjusted hazard ratio (aHRs) and 95% confidence intervals (95% CIs), with adjustments for antidepressant adherence and additional covariates.

Results: Higher levels of PA (frequency, MET) were significantly associated with a reduced risk of overall dementia (P for trend <0.001). Individuals who exercised ≥5 times per week had a 13% lower risk of dementia compared with non-exercisers (aHR, 0.87; 95% CI, 0.78-0.95). A comparable pattern was observed for MET levels, with the ≥1000 MET-min/week group exhibiting a lower risk (aHR, 0.84; 95% CI, 0.75–0.93) than the 0 MET-min/week group. A significant sex-specific difference was observed only in the frequency of PA (P for interaction = 0.017)

Discussion: We identified that the association between PA frequency and dementia risk may vary depending on the sex of the patients with depression. To our knowledge, this is the first cohort study to link early post-diagnosis PA with dementia risk in newly diagnosed depression patients while adjusting for major covariates, including anti-depressant adherence and comorbidities, both of which are key clinical variables in this population.

Conclusion: Our findings indicate that increased physical activity, measured by both frequency and METs, is associated with a reduced risk of dementia in the early post-depression period. These findings highlight the critical importance of early PA as a preventive strategy against dementia following a depression diagnosis, and underscore the need for clinical interventions to encourage active lifestyles during this period.

ID 1696- An AI-enabled digital ecosystem supporting humane, equitable onboarding and safer clinical practice in primary care

Tolga KADIOGLU

Republic Of Türkiye Ministry Of Health, İzmir, Türkiye

Context: Seemingly harmless prescriptions, often written in primary care, can lead to life-threatening clinical situations if potential drug interactions are overlooked. This presentation highlights clinically important drug interactions that may occur with medications commonly prescribed in primary care.

Methods: Three representative cases scenarios were constructed. The cases were developed based on standard pharmacology textbooks (see "References"). The approval of an Ethics Committee was not required. References: Brunton, L. L., Hilal-Dandan, R., & Knollmann, B. C. (Eds.). (2017). Goodman & Gilman's the pharmacological basis of therapeutics (13th ed.). McGraw-Hill Education. Katzung, B. G., Trevor, A. J., & Kruidering-Hall, M. (2017). Basic and clinical pharmacology (14th ed.). McGraw-Hill Education.

Originality: It highlights foreseeable but often overlooked risks.

Lessons learned and future implications: Case 1: A patient who is prescribed clarithromycin. If the patient is concomitantly using a statin, myopathy and even rhabdomyolysis may develop. Macrolides reduce hepatic metabolism of statins, thereby increasing their adverse effects which may lead to myopathy. Case 2: A patient who is prescribed omeprazole. If the patient is using clopidogrel, an increased risk of thrombosis may occur. Omeprazole inhibits hepatic activation of clopidogrel, increasing the risk of thrombotic events. Case 3: A patient who is prescribed acetaminophen. If there is a history of chronic alcohol use, acute liver injury may develop. Chronic alcohol use increases the formation of toxic metabolites of acetaminophen.

Discussion: The presented cases demonstrate that some risks can be anticipated through brief and focused history taking.

Conclusion: Prescriptions that appear simple in primary care may lead to serious outcomes if the patient's ongoing treatments and clinical history are not adequately assessed. A basic awareness of drug interactions combined with targeted history taking is an effective and low-cost strategy for preventing avoidable adverse effects.

(2) Escola Nacional De Saúde Pública De Portugal, Lisboa, Portugal
(3) Chistus, Fortaleza, Brésil
(4) Universidade Estadual De Minas Gerais, Divinópolis, Brésil

Context: Primary Health Care (PHC) aims to provide accessible, scientifically sound, and community-centered care. It serves as both the first level of the health system and a model for clinical practice. Key PHC attributes include first-contact access, long-term patient relationships, comprehensive care, and care coordination, along with family, community, and cultural orientation.

Objectives: To examine how the attributes of Primary Health Care (PHC) influence the health care of migrants, identifying both the potential strengths and challenges of providing care to this population within the primary care context.

Methods: An integrative literature review was conducted to examine how Primary Health Care (PHC) attributes affect migrant health, identifying key challenges and opportunities. Databases searched included BVS, LILACS, and SciELO using health science descriptors in English and Portuguese.

Results: Migration creates significant barriers to health care, including linguistic, cultural, legal, and geographic obstacles. Strengthening

Primary Health Care through accessibility, cultural competence, and professional training can improve migrant health and reduce pressure on emergency services. Longitudinal care in Primary Health Care (PHC) goes beyond continuity of care, emphasizing ongoing relationships of trust between patients and professionals. It involves attentive listening, welcoming, and personalized care, which strengthen bonds, enhance problem identification, and improve service effectiveness and quality.

Discussion: Primary Health Care (PHC) for migrants requires more than access alone. While access is crucial as the first point of contact, other attributes—longitudinality, care coordination, comprehensiveness, and cultural competence—are essential for quality care. Sustained patient-provider relationships, culturally sensitive practices, and integrated care networks improve health outcomes, while barriers such as language, legal status, and geographic access continue to challenge equity. Strengthening all PHC attributes together is key to reducing disparities and enhancing the effectiveness of health systems for migrant populations.

Conclusion: Effective care coordination in Primary Health Care (PHC) requires a well-structured, connected network of services. Studies show that gaps in coordination, such as in migrant maternal care, undermine service quality, highlighting the need to integrate perspectives of users, health professionals, and the health system.

Context: The workshop Occupational Health in Family Medicine: Practical Tools for Safer, Healthier Work is designed to strengthen the integration of occupational health principles into routine family practice and primary care. Set against the broader theme of “Liberty, Equality, Fraternity,” it emphasizes the importance of enabling safe and autonomous work decisions, ensuring equitable access to preventive measures and accommodations, and fostering interprofessional collaboration under a One Health framework.

Objectives: The session’s objectives are to equip participants with the ability to define key occupational health concepts relevant to community health, apply a structured five-minute work-focused history within consultations, draft fit notes that highlight functional capacity and shared decision-making, co-develop practice policies for safe return-to-work and psychosocial risk reduction, and plan a 90-day implementation strategy with measurable clinical, equity, and value-on-investment outcomes.

Teaching method and workshop: Teaching methods are highly interactive, combining case vignettes, small-group design sprints, and toolkit walkthroughs to ensure participants not only acquire knowledge but also co-create practical tools adaptable to busy clinical workflows. The workshop

Expected outcomes: Expected outcomes include enhanced clinical capacity to integrate occupational health into family medicine, improved patient autonomy through functional capacity notes, strengthened collaboration with employers and community resources, and measurable redu

Conclusion: By the conclusion, participants will leave with a printable toolkit, a structured implementation checklist, and a clear evaluation plan, empowering them to embed a work dimension into their clinical practice, align with WONCA networks in prevention and quality, and advance humanistic, community-oriented family medicine that supports safer, healthier work for all.

Context: The COVID-19 pandemic led to a rapid deployment of teleconsultation (TC) in French primary care. Before the crisis, routine use remained limited, including in the XXXXXXX departments of XXXXXXX and XXXXX. Exploring GPs' lived experience in these island settings can inform how TC may be integrated beyond emergency conditions.

Objectives: To explore general practitioners' (GPs) lived experiences with TC during the first wave of COVID-19 in XXXXXXX and XXXXXXX.

Methods: Qualitative phenomenological study using semi-structured interviews. Five investigators conducted five independent regional sub-studies (four in XXXXXX, one in XXXXXX). Ambulatory GPs were eligible if they had used TC during the first wave; physicians-in-training and non-primary-care physicians were excluded. Interviews were conducted in French between May and December 2020. Data were analysed inductively with manual coding and triangulation, and a cross-regional interpretative synthesis produced a unified conceptual model.

Results: Fifty-five GPs were interviewed (10–13 per region). TC was widely perceived as imposed, with limited preparedness, training and secure digital infrastructure. GPs reported frustration, diagnostic uncertainty linked to the lack of physical examination, ethical concerns (notably confidentiality when using common communication apps), administrative burden, and a perceived loss of holistic, relationship-based care. At the same time, they identified benefits: continuity of care during lockdown, reduced infection risk, and legitimisation of previously informal remote acts. Over time, many described a shift from improvisation to a reasoned and selective use of TC, defining indications and limits.

Discussion: TC was not viewed as a substitute for in-person consultations but as a complementary tool for specific situations. The observed evolution—from constraint to cautious appropriation—highlights the need for regulation, training and reliable infrastructure, particularly in underserved regions, to support sustainable integration of telemedicine in primary care.

Conclusion: Strengthening secure digital infrastructure and practical guidance, alongside clinician training, may facilitate safe and equitable long-term use of TC beyond crises.

(3) Instituto São Lucas De Pato Branco, Pato Branco, Brésil

Context: Twin pregnancy is a high-risk obstetric condition associated with prematurity and selective intrauterine growth restriction. Although management mainly occurs in specialized care, Primary Health Care is strategic for early risk identification, prenatal follow-up, and care coordination, impacting maternal and perinatal outcomes.

Methods: This report describes the care of a 33-year-old woman, G5P1A3, with a dichorionic twin pregnancy in a bicornuate uterus, followed in prenatal care and timely referred to high-risk services. One fetus developed severe selective intrauterine growth restriction, with estimated fetal weight below the 10th percentile and progressive Doppler abnormalities, including absent and reversed end-diastolic flow, associated with fetal distress. Coordination between Primary Health Care, specialized services, and the hospital team enabled intensified surveillance and shared decision-making regarding pregnancy interruption. Delivery occurred by cesarean

section at 34 weeks and 2 days, with immediate neonatal support and multidisciplinary follow-up.

Originality: This case demonstrates that Primary Health Care acts beyond care coordination, integrating with specialized services from early prenatal follow-up. Its role in prevention, early risk detection, and longitudinal monitoring ensured continuity of care and was essential for comprehensive maternal and child health care, despite obstetric resolution in specialized settings.

Lessons learned and future implications: Early identification of risk factors during prenatal care, combined with timely referral and effective articulation between Primary Health Care and specialized services, supports appropriate clinical decision-making and the prevention of severe perinatal outcomes. Strengthening PHC as an active component of shared care improves the quality of maternal and child health services.

Discussion: Selective intrauterine growth restriction in dichorionic twin pregnancies is associated with placental abnormalities and may be aggravated by uterine malformations. In this case, a bicornuate uterus likely contributed to placental insufficiency in one fetus, with progressive Doppler abnormalities supporting timely pregnancy interruption. Although management occurred in specialized care, Primary Health Care was fundamental for early risk recognition, referral, and longitudinal follow-up, positively impacting perinatal outcomes.

Conclusion: Integrated action between Primary Health Care and specialized services is essential for the safe management of twin pregnancies complicated by selective intrauterine growth restriction. Through surveillance, shared care, and continuity of assistance, PHC plays a decisive role in improving perinatal outcomes, even in highly complex obstetric settings.

ID 1139- An integrated curriculum based pilot program for resilience and reflection for GP registrars

Busra BILIK SEZER [1] , Metehan GUZELKAYA [2]

(1) Tuzluca Family Health Center, Igdir, Türkiye
(2) Department Of Family Medicine, Ankara Training And Research Hospital, Ankara, Türkiye

Context: A popular documentary series presents experimental “Medicine 3.0” longevity protocols (e.g., genetic risk awareness, thermal stress, fasting, functional training) framed as strategies to extend healthspan. The question for family medicine is how to translate such content into feasible, equitable, evidence-informed preventive care.

Objectives: To classify the documentary’s featured interventions; appraise feasibility, safety considerations, and equity risks for primary care; and translate them into deliverable counselling pathways.

Methods: We conducted a structured analysis of the documentary’s featured interventions and a focused narrative appraisal of supporting clinical evidence to assess feasibility and potential risks in primary care. The interventions were mapped to actionable, patient-centred prevention and behaviour-change pathways deliverable within routine consultations. No patient-level data were collected.

Results: The interventions mapped to four practical counselling domains: (1) cardiometabolic risk reduction and follow-up, (2) function/strength optimisation, (3) stress management and sleep/wellbeing, and (4) nutrition behaviour strategies (including caloric restriction/fasting approaches). Three key implementation requirements were identified: (i) shared decision-making and safety screening before intensive protocols, (ii) health literacy and motivational interviewing to support adherence, and (iii) explicit attention to accessibility when biomarker tracking or personalised strategies are promoted to avoid widening inequities.

Discussion: Lifestyle targets (stress management, caloric restriction, and muscle strength optimisation) are broadly transferable,

yet intensity and resource requirements may limit scalability. Primary care can reframe “protocols” into graded, culturally appropriate, and sustainable plans.

Conclusion: Documentary-driven interest in longevity can be leveraged in family medicine if translated into safe, equitable, evidence-informed preventive care pathways that prioritise behaviour change support and accessibility.Ultimately, the documentary poses a fundamental question for both physician and patient: "Do we seek merely a longer life, or a more meaningful one?"

(3) Department Of Nutrition And Dietetics, Faculty Of Health Sciences, Igdir University, Igdir, Türkiye

Context: Biotinidase deficiency (BD) is an autosomal recessive metabolic disorder that can lead to severe neurological and cutaneous symptoms if untreated. Early detection through neonatal screening is vital for preventing irreversible complications. Given the high rates of consanguineous marriages in certain regions of Türkiye, local data are essential for assessing regional prevalence within the National Newborn Screening Program (NTP).

Objectives: To provide a preliminary evaluation of screening outcomes, interim recall rates, and the preliminary incidence of profound and partial BD among newborns in Igdir province.

Methods: This ongoing retrospective descriptive study analyzes data from all newborns screened in Iğdır between 2012 and 2025. Screening is conducted via the colorimetric method on dried blood spots (Guthrie cards). Infants with suspected low enzyme activity are recalled for repeat testing and quantitative enzyme analysis. Descriptive statistics were used to calculate interim recall rates and incidence estimates for profound (<10% activity) and partial (10-30% activity) BD.

Results: Based on the preliminary data analysis of approximately 25,000 newborns (interim estimate), initial positive screening results were observed in 458 infants (approx. 1.83%), who were subsequently recalled for confirmatory testing. To date, preliminary diagnostic workups have identified 114 cases classified as profound deficiency and 170 as partial deficiency. Current projections suggest an incidence rate of 1 in 62 in the Igdir region, which is markedly higher than national and global averages.

Discussion: The high interim recall rate may reflect pre-analytical variability in dried blood spot sampling and/or increased genetic risk in the region; final analyses are ongoing to validate incidence estimates and programme performance metrics.

Conclusion: Interim findings suggest a high regional prevalence of BD in Igdir, underscoring the indispensable role of the NTP in Eastern Anatolia. Optimizing pre-analytical sample collection and recall follow-up may improve programme efficiency. Family physicians are central to counselling, long-term management, and follow-up of confirmed cases.

(4) Sath Nhs Trust, Telford, Shropshire, Uk, Royaume-Uni

Context: Antibiotic use to combat infections is common everwhere; however, antimicrobial resistance (due to indiscriminate use of antibiotics) has become a global challenge. The World Health Organization (WHO) has declared antimicrobial resistance among the top 10 global public health challenges to mankind. Healthcare professionals are actively involved

in the process of prescribing, dispensing and administering antibiotics.

Objectives: Antibiotics are extensively dispensed over the counters, even without prescriptions and simultaneously it is becomming more and more difficult to treat serious infections because of increasing antimicrobibial resistance to antibiotics; we assessed the knowledge, attitudes and practices regarding antibiotic use and antibiotic resistance among healthcare professionals working in a tertiary hospitals of Pakistan.

Methods: A hospital-based cross-sectional survey was carried out in Dec. June, 2025 involving 350 healthcare workers at nine teaching hospitals of Abbottabad (KPK Province); Islamabad (ICT); Lahore (Punjab Province) and Muzaffarabad-AJK (Kashmir) Pakistan, to ensure participation of all ethnic & regional population groups of Pakistan. A purposive sample of healthcare workers across diverse professional roles was surveyed using a structured, validated and pilot tested questionnaire on antibiotic use and resistance. Data was analyzed by using SPSS v25 for descriptive statistics and to summarize participant characteristics and inferential tests to explore variable associations.

Results: Medics constituted the dominant professional group (59%). Most of the health care respondents (80%) were aware of the appropriate use of antibiotics; however, premature discontinuation of antibiotics and reuse of leftover antibiotics was fairly common. The detailed results will be presented in WONCA Paris-2026.

Discussion: Our Findings highlights the urgent need for focussed education among all healthcare workers, especially nurses & allied health workers. Like rest of the developing countries, majority of healthcare professionals were well versed with knowledge of antibiotics use and their resistance; however, still gap in knowledge, attitude and practices exist and warrants awareness strategies & interventions.

Conclusion: The study identified persistent gaps in healthcare workers' knowledge, attitudes, and practices regarding antibiotic use and resistance, despite encouraging awareness in Pakistan.

(1) College Of Family Physicians Of Canada, Windsor, Canada
(2) University Of Warwick, Coventry, Royaume-Uni
(3) Royal College Of General Practitioners, Warwick, Royaume-Uni

Context: Karoshi, a Japanese term meaning "death due to overwork," describes fatal physical and psychological consequences associated with chronic occupational stress, excessive workload, and burnout. While traditionally recognised in corporate settings, the concept is increasingly relevant to General Practice. Rising consultation demand, workforce shortages, administrative burden, and emotional labour place family physicians at growing risk. Understanding Karoshi within a primary care context is essential for clinician wellbeing, patient safety, and workforce sustainability.

Objectives: Help participants recognise early warning signs of burnout and overwork in themselves and colleagues. Attendees will reflect on subconscious behaviours, including co-dependent traits and the "hero narrative" in General Practice, that increase burnout risk. They will explore practical strategies to set healthier boundaries, manage workload sustainably, and foster shared responsibility, while understanding how clinician wellbeing directly influences patient safety and quality of care.

Teaching method and workshop: Brief teaching segments will be combined with reflective exercises and facilitated group discussions in this highly interactive session. Participants will examine personal and systemic risk factors for overwork and burnout, using case-based examples to il

Expected outcomes: Increased self-awareness of behaviours that contribute to burnout and overwork. Participants will leave with practical tools to protect their emotional, physical, and mental wellbeing, reduce co-dependent working patterns, and adopt more sustainable appro

Conclusion: General practice is losing physicians worldwide due to increasing workload and burnout. Karoshi represents an extreme, yet preventable, outcome of unrecognised burnout among family physicians. By creating space for reflection, discussion, and practical skill-building, this workshop supports clinicians at all career stages to recognise risk, challenge unhealthy patterns, and prioritise wellbeing. Caring for clinicians is essential to providing safe, effective care, as well as supporting workforce retention.

ID 99- An Unusual Foreign Body Causing Symptoms After 40 Years: A Case Report

Zarına AYIK, Konul ABDULLAYEVA, Vildan MEVSIM, Ozan ELIAÇIK

Department Of Family Medicine, Dokuz Eylul University Faculty Of Medicine, İzmir, Türkiye

Context: Acute abdominal pain in adolescent females is a common but high-risk presentation in primary care. Gynecological emergencies such as ovarian torsion require rapid recognition and urgent referral to prevent loss of ovarian function. Additionally, incidental findings during acute evaluation may uncover previously unrecognized hereditary conditions. This case highlights the critical gatekeeping role of family physicians in both emergency recognition and holistic follow-up.

Methods: A 12-year-old girl presented to a primary care center with her mother, reporting one week of left lower quadrant abdominal pain with sudden worsening on the day of admission, resulting in difficulty walking. On examination, her general condition was poor, and marked guarding and rebound tenderness were noted in the left lower quadrant. Vital signs were stable, but laboratory testing revealed anemia (hemoglobin 8.9 g/dL). Given the acute abdomen findings, the patient was urgently referred to the emergency department. Secondary care imaging with ultrasonography and contrast-enhanced computed tomography demonstrated a ruptured left ovarian cyst with associated ovarian torsion and intra-abdominal free fluid. Emergency surgery confirmed these findings, and appropriate surgical management was successfully performed. During further thoracoabdominal imaging, incidental cystic renal changes with kidney torsion were identified. This prompted family screening, which revealed cystic kidney disease in both the patient's mother and sister, suggesting a familial cystic kidney disorder. The family was referred for nephrology and genetic evaluation.

Originality: This case uniquely combines a gynecological emergency with the incidental detection of a hereditary renal condition, emphasizing the extended impact of primary care–initiated evaluation.

Lessons learned and future implications: Primary care physicians should maintain a high index of suspicion for gynecological causes of acute abdomen in adolescents and recognize the importance of follow-up for incidental findings. Family screening can enable early diagnosis of hereditary diseases.

Discussion: This case emphasizes the need for rapid recognition of ovarian torsion in adolescents with acute abdominal pain in primary care. Early referral was crucial for timely management. .

Conclusion: Timely primary care recognition and referral prevented serious gynecological complications and facilitated early identification of a familial renal disorder, underscoring the integrative role of family medicine. Acute Abdomen; Ovarian Torsion; Ovarian Cysts; Adolescent; Polycystic Kidney Diseases; Primary Health Care

ID 1160- Analysis of Artificial Intelligence-Related Theses in Turkey: Clinical Trends and the Family Medicine Perspective

Zeynep PEKEL, Alperen KÜÇÜKUYSAL, Vildan MEVSIM

Department Of Family Medicine, Dokuz Eylul University, Izmir, Türkiye

Context: During my rheumatology rotation, I encountered a woman in her early forties with longstanding back, hip, and shoulder pain lasting more than twelve years. Her pain severely restricted daily functioning and had led to repeated healthcare encounters without a unifying diagnosis. She was raising three children alone while her husband was incarcerated and was receiving venlafaxine 150 mg daily for a chronic psychiatric condition. Over time, she had lost confidence that her symptoms could be adequately explained or treated.

Methods: I conducted a comprehensive clinical assessment, including detailed history-taking, physical examination, and review of national electronic health records and prior imaging. On examination, I observed deep ulcerated injection sites on both upper thighs. The patient disclosed self-administering intramuscular diclofenac injections two to three times daily to maintain mobility, without awareness of the associated risks. Her records documented more than thirty hospital visits within the previous year and multiple MRI and CT scans, all reported without a definitive diagnosis. Rather than requesting further investigations, we reviewed her existing sacroiliac MRI images directly together with the supervising rheumatologist.

Originality: This experience highlighted that diagnostic failure may persist not due to lack of data, but due to fragmented interpretation. The turning point was not additional testing, but integrating existing information into a coherent clinical narrative.

Lessons learned and future implications: This encounter reshaped my approach to patients with chronic, unexplained symptoms. I learned the importance of longitudinal pattern recognition, careful review of prior assessments, and exploration of patients' social context and health literacy. Social vulnerability, coping strategies, and misunderstanding of treatments can significantly influence symptom expression and healthcare utilization.

Discussion: Direct review of imaging revealed grade 3 sacroiliitis with erosions, consistent with ankylosing spondylitis. When this diagnosis was explained, the patient stated it was the first time her symptoms "made sense." Previous encounters had addressed isolated complaints rather than the underlying disease process.

Conclusion: This reflection reinforces that effective care is not always achieved by escalating investigations, but by synthesizing existing clinical information within the patient's broader life context. Seeing the whole story—medical, social, and emotional—can be transformative in the care of chronic pain.

ID 292- Analysis of the ATP2B1 Polymorphism on Blood Pressure Based on Smoking and Drinking Habits: from Genome and Epidemiology Study

Elena SURDULEASA, Minerva Claudia GHINESCU

Titu Maiorescu Faculty Of Medicine, Bucharest, Bucharest, Roumanie

Context: At the European level, the population is undergoing a continuous aging process. In 2021, there were approximately 215 million individuals age over 60 years, and by 2050, this number is projected to exceed 300 million. The dependency ratio (people over 65 whose pensions and health insurance depend on young contributors aged 15-64) will decrease, so that there will be approximately two contributors per pensioner, instead of three, by 2070. Sarcopenia is associated with higher incidence of falls and fractures and with the onset or worsening of chronic conditions such as type 2 diabetes mellitus, vascular dementia, Alzheimer's disease.

Objectives: The aim of this study is to identify the prevalence of sarcopenia at a primary care

unit and to establish if there is a link between sarcopenia and the educational level.

Methods: The qualitative prospective study was conducted in 2025 and it included 69 patiens aged over 65 years, with different pathologies. To identify the prevalence of sarcopenia were used the hand grip test, fat free body mass index (FFMI) determined by using bioelectrical impedance analysis and the 400 m walk test. Studies from the literature have proven that FFMI has a strong positive correlation with the appendicular skeletal muscle mass index (ASMI) and could be employed as a surrogate marker for screening in sarcopenia. Thus, this study was based on the cut-off values established by European Working Group on Sarcopenia in Older People 2, while substituting the ASMI values, for those established for the FFMI by the European Society of Clinical Nutrition and Metabolism.

Results: The study included 35 women and 32 men. Our findings showed that probable sarcopenia was found in 21 women and 32 men, confirmed sarcopenia in 3 women and 12 men, severe sarcopenia in 3 women and 3 men. 3 out these only had primary school studies, 2 secondary school studies and 1 went to trade school.

Discussion: These findings showes that sarcopenia can be related with the level of education, higher education giving more understanding of the importance of balanced meal and proper physical activity.

Conclusion: Future research will expand the participant pool to further analyze the impact of sarcopenia.

ID 557- Analyzing the ratio between prenatal consultations and live births in Brazil: spatial and professional patterns from 2008 to 2023

Zeynep PEKEL, Sümeyra DELIKKAYA, Vildan MEVSIM

Department Of Family Medicine, Dokuz Eylul University, Izmir, Türkiye

Context: Atrial fibrillation (AF) is common in older adults and is strongly associated with ischemic stroke and transient ischemic attack (TIA). Anticoagulant therapy is essential for stroke prevention; however, long-term adherence is often suboptimal. In primary care, unrecognised treatment discontinuation may expose patients to avoidable cerebrovascular risk.

Methods: A 76-year-old woman presented to primary care with sudden numbness in her left hand lasting approximately five minutes, which resolved completely. She had no prior similar episodes. Her medical history included atrial fibrillation and hypertension. On examination, she was alert, cooperative, and fully oriented. No focal neurological deficits were detected. Blood pressure was 160/100 mmHg. An electrocardiogram performed in the primary care setting confirmed atrial fibrillation. During medication review, the patient reported that she had stopped her prescribed anticoagulant therapy two years earlier on her own initiative, without consulting a physician. Given the presence of AF, disclosure of anticoagulant discontinuation, and a brief focal neurological deficit with full recovery, a provisional diagnosis of transient ischemic attack was considered. The patient was urgently referred to the emergency department for further evaluation. A key limitation of this case was the complete resolution of symptoms at presentation, which could have led to underestimation of risk without careful clinical assessment.

Originality: While the association between AF and thromboembolic events is well established, this case demonstrates how treatment non-adherence may remain undetected until an acute presentation in primary care. It highlights routine medication review as a critical safety practice.

Lessons learned and future implications: This case reinforces the need for regular assessment of anticoagulant adherence in patients with AF. Even brief, self-limiting neurological symptoms should prompt urgent evaluation. Improving patient education and continuity of care may help prevent avoidable cerebrovascular events.

Discussion: TIA often precedes ischemic stroke. Early recognition in primary care enables timely referral and intervention, potentially reducing long-term neurological morbidity.

Conclusion: Unmonitored discontinuation of anticoagulant therapy in patients with atrial fibrillation carries significant risk. Primary care plays a crucial role in identifying silent treatment gaps and initiating timely preventive action.

(1) Modality Partnership, Nationwide, Royaume-Uni
(2) Liberate Ai, Nationwide, Royaume-Uni

Context: Long-term conditions (LTCs) are the largest driver of primary care workload globally. As populations age and multimorbidity rises, traditional manual recall systems can no longer keep pace. Many health systems face the same structural pressures: rising demand, increasing emergency presentations, and limited workforce capacity. AI-enabled recall offers a practical, scalable and evidence-based way to modernise LTC management by shifting care from reactive to proactive. Worldwide, LTCs account for a substantial proportion of primary care appointments, outpatient activity and hospital admissions. When recalls rely on manual phone calls, letters or opportunistic reviews, patients fall through gaps, clinical risk rises, and emergency demand increases. Digital and AI-supported recall pathways can automate invitations, identify non-responders, and help prioritise patients most at risk of deterioration. These models support planned care over emergency care, enabling clinicians to intervene earlier and more effectively. The workshop focuses on implementation principles that work in low-, middle- and high-resource settings, emphasising safety, inclusion and sustainable workflow redesign.

Objectives: Participants will be able to: 1. Understand the components of an AI-enabled LTC recall pathway and how these complement existing systems. Redesign workflows to support proactive, population-level LTC management. Apply governance, clinical safety and risk-stratification principles. Build digital and non-digital pathways to ensure inclusion. Introduce and scale recall models with strong staff and patient engagement.

Teaching method and workshop: Focused presentations on proactive care models and workflow redesign. Mentimeter exercise: participants vote on their biggest LTC system barriers (e.g., demand spikes, workforce limits, missed recalls). Small-group reflection on transferable implementatio

Expected outcomes: Participants gain a clear, adaptable framework for modernising LTC recall and shifting systems toward proactive, preventative care. They leave with practical steps to evaluate readiness, engage teams, and build hybrid recall pathways suited to their own h

Conclusion: This workshop provides a scalable, internationally relevant model for strengthening LTC management using digital and AI-enabled tools—supporting safer care, earlier intervention and more sustainable primary care systems.

ID 1514- Antibiotic Prescribing Patterns for Upper Respiratory Tract Infections in General Practice: A Case Series

Yusra HASHMI [(1)], Khunsha FATIMA [(2)], Akram HUSSAIN [(3)]

(1) Royal College Of General Practitioners, Warwick, Royaume-Uni
(2) University Of Warwick, Coventry, Royaume-Uni
(3) College Of Family Physicians Of Canada, Windsor, Canada

Context: Co-dependency subtly permeates everyday relationships, presenting as normal dynamics as a ‘giver’ and ‘taker’, between doctor/patient, parent/child, spouses, etc. While healthy interdependence is essential, difficulties arise when these patterns become habitual cycles of overgiving and rescuing. In General Practice, co-dependency is frequently overlooked, causing clinician burnout, compassion fatigue, blurred boundaries, and

patient overdependence. It may also present in patients as medically unexplained symptoms, chronic pain, and fatigue. Describing real patient experiences and reflective clinical practice, we will explore co-dependency as a hidden cause of distress in both clinicians and patients, highlighting its relevance to wellbeing, sustainability, and quality of care.

Objectives: Support participants in recognising co-dependent relational patterns in clinical and personal contexts, understanding how these dynamics contribute to burnout and patient overdependence, and developing practical strategies to promote healthier boundaries, shared care, and patient autonomy. Encourage participants to reflect on their own relational habits and explore ways to foster more compassionate, empowering and balanced interactions in General Practice.

Teaching method and workshop: Helping participants identify features of unhealthy relational patterns using real-life scenarios to facilitate reflection and discussion. Explaining a clear definition of co-dependency. Describing the Karpman Drama Triangle to explore shifting roles of V

Expected outcomes: Participants will be equipped to recognise co-dependency as a potential contributing factor and an “ingredient in the pain soup” for patients presenting with chronic pain and fibromyalgia. They will develop skills to address unmet emotional needs through

Conclusion: Co-dependency is a modifiable yet under-recognised influence on wellbeing, and is rarely addressed explicitly in medical education. This workshop equips clinicians with practical frameworks to recognise and disrupt unhealthy relational dynamics, setting healthy boundaries while empowering patients to protect clinician wellbeing and supporting more sustainable care.

ID 136- Antibiotic Prescriptions and the Risk of Overweight and Obesity in Children between 2 and 17 years old: A French Retrospective Primary Care Cohort Study

Sian KNIGHT [(1)], Tom RATCLIFFE [(1)], Belinda ROELOFS [(2)], Mina GUPTA [(1)], Nina JHITA [(1)], Vincent SAI [(1)]

(1) Modality Partnership, Nationwide, Royaume-Uni
(2) Liberate Ai, Nationwide, Royaume-Uni

Context: Traditional long-term condition recall systems relied on repeated manual calls, letters and SMS reminders. These processes were time-consuming, inconsistent across sites and often frustrating for staff. Younger adults in particular struggled to engage, finding it difficult to book appointments during working hours. Operational pressures meant that non-responders absorbed significant administrative time, and staff were concerned that patients with the greatest needs were being overlooked.

Methods: Primary care teams serving over 500,000 patients co-designed an innovative agentic AI-supported recall process that automated initial invitations at-scale and gathered clinical information before appointments were booked. Patients able to complete a digital review could do so at their convenience. Staff then received a clear list of individuals who needed personal follow-up, allowing them to prioritise time for patients requiring support. A key strength was the clarity and consistency of the new workflow. Initial staff concerns included the perception that some patients might be disadvantaged if they could not engage digitally. However, staff found that the streamlined digital flow freed capacity for deeper, more personalised conversations with patients needing additional help. Safety checks were embedded at critical points and concerns about clinical safety addressed in DTAC, DPIA and DCB0129/0160-aligned safety assessment.

Originality: Existing recall models focus on volume rather than prioritisation. This approach differed by using digital automation to reduce low-value work while improving equity. The hybrid model—automated where appropriate, manual where needed—allowed teams to redistribute effort rather than simply accelerate existing tasks.

Lessons learned and future implications: Concerns about digital exclusion diminished when staff saw extremely high patient acceptance and the solution helped to identify and support vulnerable patients more proactively. Future development will focus on expanding to other conditions and refining templates to reflect multimorbidity.

Discussion: This experience demonstrates that digital automation can enhance—not replace—relational care when implemented with clear workflows and ongoing staff involvement. The approach aligns with broader primary care goals of access, continuity and personalised care.

Conclusion: With 68% immediate digital uptake, Agentic-AI recall offers a practical, transferable method for modernising LTC management. Intelligent risk stratification and prioritisation resulted in a 41% reduction in appointments, offering a sustainable solution to operational pressures internationally.

ID 914- Antimicrobial Stewardship – prescribing practices in ethnically diverse urban population

Sedanur AKSU, Umut GÖK

Department Of Family Medicine, Izmir City Hospital, Izmir, Türkiye

Context: Herpes zoster is a common presentation in general practice and usually managed with antiviral therapy. However, potential implications for household members, including transmission risk and preventive counselling may be underestimated during consultations. A family-centred perspective is essential to address overlooked aspects in primary care.

Methods: A 55-year-old woman with type 2 diabetes mellitus presented with a painful vesicular rash involving the right upper face, scalp and ear with neuropathic pain radiating to the right shoulder. Examination showed a dermatomal vesicular eruption without facial nerve involvement. Herpes zoster was diagnosed, antiviral treatment was initiated, and follow-up was planned. Isolation was recommended with emphasis on pharmacological management. At follow-up, the patient showed clear improvement. She reported her 22-year-old daughter in the same household had developed fever. She was too advised to attend the clinic. When she presented next day, itchy vesicular lesions were noted on her face and upper body. The rash had started approximately 12 hours after the onset of fever. She was diagnosed with primary varicella infection, despite reporting complete childhood vaccination. This reflection is based on routine clinical practice and follow-up, highlighting continuity of care and limitations related to the prioritization of acute management over preventive counselling.

Originality: While herpes zoster and varicella transmission are well described in the literature, this case offers a contribution on a frequently overlooked aspect of primary care practice. Unlike hospital-based case reports, this reflection emphasizes continuity, follow-up, and family- centred decision-making in general practice.

Lessons learned and future implications: This case demonstrates that herpes zoster management should extend to household members regardless of reported vaccination status. It highlights the need for clear, structured isolation counselling and systematic consideration of household contacts. Future practice may benefit from integrating household risk assessment into routine herpes zoster consultations in primary care.

Discussion: The case illustrates how everyday clinical priorities may unintentionally limit preventive counselling. Follow-up visits provide critical opportunities to identify household risks and reinforce preventive strategies within a family-centred framework.

Conclusion: Herpes zoster should be approached as a condition with potential household consequences in primary care. Incorporating isolation guidance, household contact assessment, and continuity of care can strengthen preventive practice and reduce secondary infections.

ID 125- Applying a Health Justice Lens to Curriculum Review in Primary Care Education: A Practice-Based Reflection

*Beata BLAHOVA

General Practice, Krompachy, Slovaquie

Context: Thyreotoxicosis means that there is too much thyroid hormone in the body. Tremor in young patients is a common neurologic complaint. Essential tremor and psychogenic causes are frequently suspected. Tremor may be the presenting sign of endocrine disorders, which can remain undiagnosed for months.

Methods: 34 years old woman presented to GP in September. She complained about hands tremor, worsened with nervous tension, which she attributed to discontinuation of antidepressants month ago. During examination tremor was not present, no other pathologic findings were found. Neurologic examination revealed no significant abnormalities. Essential tremor was diagnosed. Patient sought care again, in November, with her neck appeared swollen, palpitation and fatigue.The thyroid gland was palpably enlarged, tremor of the upper limbs, tachycardia of 130/min were noted. Laboratory findings revealed TSH 0.01. She was reffered to endocrinologist for futher examination of thyreotoxicosis. She was restarted on tiamazol 20 mg per day, vitamin B6, betablockers.

Originality: This case highlights the importance of repeated clinical evaluation in patients with persistent or evolving tremor symptoms. Tremor can result from neurological, psychiatric, toxic, or endocrine causes. In a young woman with a history of antidepressant discontinuation, a psychogenic or iatrogenic tremor is often considered most likely. The initial diagnosis of essential tremor was reasonable at first, as no other alarming signs were present.

Lessons learned and future implications: Even when tremor initially appears benign, clinicians must remain vigilant for systemic causes, especially when additional symptoms emerge. Re-evaluation based on current findings rather than prior assumptions can prevent diagnostic delay.

Discussion: Endocrine causes of tremor are often underdiagnosed, especially when patients are initially evaluated in a neurological setting. This case underscores the importance of assessing tremor in the context of the overall clinical picture and not excluding systemic diseases based solely on history or prior assumptions.

Conclusion: This case emphasizes that tremor should not be evaluated in isolation. Clinical signs may be dynamic and change over time. Assuming that an initial diagnosis remains valid can lead to overlooking serious conditions. When new symptoms arise the differential diagnosis should be reconsidered. Reassessment of patients with changing symptoms is essential, as new clinical signs may redirect diagnostic reasoning.

Context: Acute abdominal pain in adolescent females is a common but high-risk presentation in primary care. Gynecological emergencies such as ovarian torsion require rapid recognition and urgent referral to prevent loss of ovarian function. Additionally, incidental findings during acute evaluation may uncover previously unrecognized hereditary conditions. This case highlights the critical gatekeeping role of family physicians in both emergency recognition and holistic follow-up.

Methods: A 12-year-old girl presented to a primary care center with her mother, reporting one week of left lower quadrant abdominal pain with sudden worsening on the day of admission, resulting in difficulty walking. On examination, her general condition was poor, and marked guarding and rebound tenderness

were noted in the left lower quadrant. Vital signs were stable, but laboratory testing revealed anemia (hemoglobin 8.9 g/dL). Given the acute abdomen findings, the patient was urgently referred to the emergency department. Secondary care imaging with ultrasonography and contrast-enhanced computed tomography demonstrated a ruptured left ovarian cyst with associated ovarian torsion and intra-abdominal free fluid. Emergency surgery confirmed these findings, and appropriate surgical management was successfully performed. During further thoracoabdominal imaging, incidental cystic renal changes with kidney torsion were identified. This prompted family screening, which revealed cystic kidney disease in both the patient's mother and sister, suggesting a familial cystic kidney disorder. The family was referred for nephrology and genetic evaluation.

Originality: This case uniquely combines a gynecological emergency with the incidental detection of a hereditary renal condition, emphasizing the extended impact of primary care–initiated evaluation.

Lessons learned and future implications: Primary care physicians should maintain a high index of suspicion for gynecological causes of acute abdomen in adolescents and recognize the importance of follow-up for incidental findings. Family screening can enable early diagnosis of hereditary diseases.

Discussion: Timely primary care recognition and referral prevented serious gynecological complications and facilitated early identification of a familial renal disorder, underscoring the integrative role of family medicine.

Conclusion: Timely primary care recognition and referral prevented serious gynecological complications and facilitated early identification of a familial renal disorder, underscoring the integrative role of family medicine. Keywords (MeSH) Acute Abdomen; Ovarian Torsion; Ovarian Cysts; Adolescent; Polycystic Kidney Diseases; Primary Health Care

Context: Child and adolescent sexual violence as a public health problem poses ethical, clinical, and emotional challenges to healthcare professionals. This context needs to be explored for the improvement of healthcare services.

Objectives: To describe the emotional aspects of healthcare professionals in the care of victims of child and adolescent sexual violence.

Methods: Qualitative and descriptive study conducted in a program at a pediatric hospital in the State of Ceará, Brazil, with 18 healthcare professionals (social workers, psychologists, doctors, nurses, and pharmacists). Semi-structured interviews were conducted, with data analyzed using Thematic Content Analysis. This study is part of a larger project, approved by the Ethics Committee of the Federal University of Ceará, under opinion number 7,500,752.

Results: The professionals' statements reveal psychological suffering, feelings of distress, anguish, and a sense of helplessness in some cases, also linked to other factors that challenge their work, such as overload, weakened work relationships, and a work structure that does not fully support compassionate care. There was thus a perceived absence of institutional support mechanisms for caregivers, as the topic 'institutional strategies to improve working conditions' was only mentioned in the context of technical training actions from the professional training plan within the service program.

Discussion: The need for emotional support is evident, as it is observed from the findings and

reflections presented in this study that the continuous exposure of these healthcare professionals to situations of child and adolescent sexual violence has significant repercussions on their mental health (something that the literature in the field also reflects). These aspects can be exacerbated by adverse institutional conditions, such as work overload, weakened relationships, and structural limitations.

Conclusion: The study understood that emotional aspects are central dimensions in addressing child and adolescent sexual violence and are related to working conditions. The absence of institutional caregiver support mechanisms highlights a persistent challenge in organizing health services. It becomes necessary to implement strategies that integrate technical training and psychosocial support for professionals, as these actions can strengthen care, protect workers, and improve attention to children and adolescents.

ID 651- Approach to abnormal uterine bleeding in non-pregnant women

Konul ABDULLAYEVA, Zarına AYIK, Mevsim VILDAN

Department Of Family Medicine, Dokuz Eylul University Faculty Of Medicine,, Izmir, Türkiye

Context: Unintentional weight loss, palpitations, and fatigue are common but non-specific complaints in primary care. These symptoms are frequently attributed to stress, anxiety, or lifestyle factors, particularly in young and middle-aged adults. However, endocrine disorders such as hyperthyroidism must be considered, as delayed diagnosis may lead to significant cardiovascular and metabolic complications. Primary care plays a critical role in early recognition and appropriate referral.

Methods: A 34-year-old woman presented to a primary care clinic with a two-month history of palpitations, fatigue, heat intolerance, excessive sweating, nervousness, insomnia, and a 5-kg unintentional weight loss despite increased appetite. She also reported exertional dyspnea when climbing stairs. She had no known chronic disease and was not using regular medication. Family history was positive for thyroid disease on the maternal side. On examination, she appeared anxious but cooperative. Blood pressure was 120/70 mmHg, heart rate 112 beats/min, and temperature 36.7°C. Physical examination revealed a mildly enlarged, non-tender thyroid gland, fine bilateral hand tremor, warm moist skin, and regular tachycardia. Based on clinical suspicion, targeted laboratory tests were ordered. Results showed suppressed TSH (<0.01 µIU/mL) with elevated free T4 (2.8 ng/dL) and free T3 (6.1 pg/mL), confirming hyperthyroidism.

Originality: This case illustrates how classic hyperthyroid features may initially present as non-specific complaints and highlights the diagnostic value of focused history-taking and physical examination in primary care.

Lessons learned and future implications: Unintentional weight loss combined with palpitations and tremor should prompt thyroid function testing in primary care. Early recognition enables timely intervention and prevents avoidable complications.

Discussion: The overlap between hyperthyroidism and anxiety-related symptoms can delay diagnosis. Primary care physicians are uniquely positioned to integrate clinical clues and initiate appropriate investigations.

Conclusion: Systematic clinical assessment in primary care allowed early diagnosis of hyperthyroidism and timely referral, underscoring the essential role of family physicians in managing endocrine presentations. MeSH key words Hyperthyroidism; Graves Disease; Weight Loss; Palpitations; Primary Health Care; Family Medicine; Thyroid Hormones

Context: Undesired loneliness remains under-addressed in primary care, yet family physicians are seeing more patients who use AI applications for companionship and emotional support. Millions of patients worldwide now form relationships with AI chatbots and virtual companions, often without telling their healthcare providers. This raises critical questions: Are patients replacing human connection with AI relationships? Should we screen for AI companion use? Can these tools help treat loneliness, or do they represent harmful social withdrawal? This workshop provides evidence-based insights to address this clinical challenge.

Objectives: - Assess and identify: Recognize patterns of AI companion use among lonely patients and distinguish beneficial from harmful presentations - Apply evidence: Evaluate current research on mental and physical health impacts of AI companionship - Screen effectively: Add practical questions about AI companion use to routine patient encounters - Develop interventions: Create patient-centered approaches for discussing AI relationships and provide appropriate referrals when use becomes problematic.

Teaching method and workshop: Introduction and framework (10 min): Overview of AI companions in patient care and learning objectives. Recognition through cases (15 min): Interactive scenarios to identify beneficial versus harmful use patterns. Evidence review (10 min): Current resear

Expected outcomes: Participants will leave with: - Assessment skills: Practical screening questions to identify patients who may benefit from or be harmed by AI companion use. - Clinical framework: Evidence-based understanding and decision-making strategies for addr

Conclusion: As AI technologies increasingly affect patients' emotional experiences, family physicians must understand how AI companionship affects health outcomes and therapeutic relationships. This workshop offers evidence-informed exploration of AI companionship as both a potential tool and clinical concern. Participants will gain practical skills to assess loneliness, provide appropriate guidance, and ensure digital relationships complement rather than replace human connection and professional care.

Context: Across the world, primary care clinicians face overwhelming documentation requirements. In many systems, clinicians spend as much time—or more—writing notes as they do in direct patient care. This administrative load contributes to burnout, reduces patient-facing time, undermines continuity and threatens workforce retention. Ambient Voice Technology (AVT) offers a transformative opportunity: accurate, real-time consultation notes produced unobtrusively during the patient encounter. When implemented safely, AVT can restore clinician capacity, improve documentation quality and strengthen the sustainability of primary care systems. Documentation burden is a universal challenge, affecting high-, middle-, and low-income settings. For some clinicians, delayed or incomplete notes affect clinical quality and introduce medico-legal risks. For others, the cumulative burden creates chronic fatigue and diminished job satisfaction. AVT provides an emerging solution by capturing the consultation narrative and generating structured notes that clinicians verify. The workshop focuses on universally transferable principles: evaluating readiness, adapting workflows, safeguarding data and achieving

cultural adoption—regardless of local infrastructure or digital maturity.

Objectives: Participants will be able to: 1. Understand how AVT works and its potential to reduce burden and improve safety. 2. Apply governance, workflow and risk-mitigation principles for safe deployment. 3. Support clinician adoption using behavioural and organisational change strategies. 4. Evaluate infrastructure and inclusion requirements in varied resource settings. 5. Adapt phased implementation models to their own health system.

Teaching method and workshop: Short presentations on documentation burden, AVT principles and implementation models. Mentimeter activity: participants vote on their biggest documentation challenges. Small-group reflection on local feasibility and potential adaptations. Facilitator-led

Expected outcomes: Participants gain an actionable framework to evaluate and introduce ambient documentation safely; strategies to strengthen workforce morale and wellbeing; and adaptable models suited to diverse healthcare systems.

Conclusion: This workshop reframes ambient transcription as a structural workforce solution, offering practical, transferable insights that enable delegates to reduce burden, enhance documentation quality and build more sustainable primary care services.

(1) Modality Partnership, Nationwide, Royaume-Uni
(2) Heidi Health, Nationwide, Royaume-Uni

Context: Clinical documentation has become a major source of workload and stress in primary care. Many clinicians routinely spent time after clinic completing notes, and occasional concerns around documentation quality created additional supervisory burden. A supportive, unobtrusive method of producing accurate notes during consultations was sought to improve clinician experience, reinforce safety and reduce administrative pressure.

Methods: Ambient voice technology was introduced in a phased, carefully supported rollout. The initial pilot involved 47 GP partners who were keen to explore the benefits. Following successful early testing, this innovative programme expanded progressively to salaried GPs, resident doctors, advanced clinical practitioners, pharmacists and nurses. This staged, at-scale rollout enabled refinement of workflows, governance processes and onboarding before adoption widened. Over time, hundreds of clinicians used the system, and more than 1.2 million minutes of consultations were transcribed, demonstrating significant scale. A key example of impact involves a clinician whose documentation raised concerns. With ambient transcription, their notes immediately became clear, accurate and well structured. This prevented the need for intensive performance-management and reinforced the value of the tool as a supportive intervention. Strengths of the programme included reduced after-hours work and improved record quality. Limitations centred on initial hesitation, addressed through gradual rollout and peer-to-peer advocacy. Safety checks were embedded at critical points and concerns about clinical safety addressed in DTAC, DPIA and DCB0129/0160-aligned safety assessment.

Originality: The model differed from typical digital transcription tools by embedding ambient capture into routine multidisciplinary practice, demonstrating applicability beyond GPs. Its dual benefit—supporting wellbeing and strengthening clinical governance—made it a novel application in primary care settings.

Lessons learned and future implications: Early adopters played an essential role in fostering trust. Allowing adoption to grow organically, rather than mandating use, ensured sustained engagement. Future expansions may include structured data extraction and integration into broader digital pathways.

Discussion: The experience highlights how ambient technology can enhance documentation while preserving clinician–patient connection. It supported both quality improvement and workforce sustainability.

Conclusion: A phased, multidisciplinary rollout of ambient voice technology across practices serving 500,000 patients improved documentation quality, reduced administrative burden and demonstrated a scalable, supportive solution for modern primary care.

ID 51- Artistic expression, self-worth, and mental health: pathways to dignity

Zarina AYIK, Konul ABDULLAYEVA, Vildan MEVSIM

Department Of Family Medicine, Dokuz Eylul University Faculty Of Medicine, İzmir, Türkiye

Context: Laryngeal cancer is a common head and neck malignancy, strongly associated with tobacco use. Early symptoms may be subtle and are frequently first encountered in primary care. Persistent hoarseness lasting longer than three weeks—particularly in high-risk individuals—should prompt urgent evaluation. Family physicians play a critical role in recognizing red-flag symptoms and initiating timely referral.

Methods: A 62-year-old man presented to a family medicine clinic with progressive hoarseness lasting one month. He also reported sore throat and unintentional weight loss of 7 kg over the same period. He was an active heavy smoker (approximately three packs per day) with a family history of lung cancer. He denied fever, night sweats, or dyspnea. Physical examination revealed marked dysphonia and a firm, non-tender left cervical lymph node measuring approximately 2 cm. Vital signs and basic measurements were within normal limits. Given the persistence of hoarseness, heavy tobacco exposure, weight loss, and cervical lymphadenopathy, a laryngeal malignancy was strongly suspected, and the patient was urgently referred to otorhinolaryngology. Three weeks later, the patient returned with hospital records. Fiberoptic and direct laryngoscopy revealed a suspicious laryngeal lesion, and biopsy confirmed squamous cell carcinoma of the larynx.

Originality: This case illustrates how a common symptom such as hoarseness can represent an underlying malignancy and emphasizes the pivotal gatekeeping role of primary care in early cancer detection.

Lessons learned and future implications: Persistent hoarseness beyond three weeks should always be evaluated carefully in primary care. Smoking history, weight loss, and cervical lymphadenopathy are critical red flags. Family physicians should maintain a low threshold for urgent referral, as early recognition can significantly affect prognosis and treatment options.

Discussion: Laryngeal cancer often presents with voice changes before advanced symptoms develop. In busy clinical settings, hoarseness may be misattributed to benign causes. This case demonstrates how systematic assessment and awareness of risk factors in primary care can prevent diagnostic delay.

Conclusion: Primary care physicians are essential in the early identification of laryngeal cancer. Careful history-taking, focused examination, and timely referral enable earlier diagnosis and improved patient outcomes. MeSH keywords (plain text): Laryngeal Neoplasms; Hoarseness; Primary Health Care; Smoking; Early Diagnosis; Squamous Cell Carcinoma

(2) Ribeirão Preto, Ribeirão Preto, Brésil

Context: Born in 1997, Malala Yousafzai was encouraged from childhood by her father to value education as a fundamental right. Her trajectory demonstrates how education can be a powerful tool for social transformation.

Methods: Experience report of health education and empowerment actions using the life of Malala Yousafzai.

Originality: The mapping of Malala's steps and actions aimed at overcoming prejudice and securing the right to education was, for the first time, associated with motivational interviewing techniques to develop self-efficacy among women in marginalized situations, based on the Characteristics of Successful Changers.

Lessons learned and future implications: Initial actions occurred in 2018. In 2019, the approaches were replicated in remote rural communities, engaging women who had dropped out of or not completed primary or higher education. In 2022, actions were carried out with women experiencing homelessness, using a conversation circle methodology.

Discussion: Stage 1 consisted of presenting Malala's story, emphasizing the importance of education in changing life perspectives for women living in peripheral areas of northeastern Brazil. Stage 2 focused on developing the concept of health, highlighting a biopsychosocial perspective for comprehensive health maintenance. The role of education in improving job opportunities, income, and family support security was emphasized. A playful and participatory activity addressed family types and the impact of role overload in contemporary women's lives. In Stage 3, women shared stories of struggle and resilience across life stages, addressing issues such as domestic violence, stigma, sexual abuse, child labor, physical and mental overload, human rights violations in arranged marriages, deprivation of education and pressure for early motherhood, emotional dependence and psychological violence, and limited access to women's health care, contraception, and family planning.

Conclusion: The empowerment of women and girls can be coordinated by family and community physicians, contributing to improved social outcomes and the construction of meaningful life projects that uphold human rights to health and quality education.

ID 1707- Assessment of Family Medicine Residents' Knowledge on Rabies and Its Prophylaxis

Konul ABDULLAYEVA, Zarına AYIK, Vildan MEVSIM

Department Of Family Medicine, Dokuz Eylul University Faculty Of Medicine, Izmir, Türkiye

Context: Falls in older adults are a common presentation in primary care and often reflect multifactorial etiologies. Polypharmacy—particularly the use of centrally acting medications—significantly increases the risk of orthostatic hypotension, dizziness, and recurrent falls. Family physicians are well positioned to identify medication-related adverse effects early and implement deprescribing strategies to prevent morbidity and unnecessary hospital referrals.

Methods: A 78-year-old woman presented to a family medicine outpatient clinic with recurrent falls over a three-month period. The falls were accompanied by dizziness and typically occurred when standing up. Her medical history included hypertension, type 2 diabetes mellitus, osteoarthritis, and hyperlipidemia. Current medications were hydrochlorothiazide, metformin, simvastatin, diazepam prescribed for insomnia, and gabapentin for chronic pain. On examination, orthostatic hypotension was detected, with a systolic blood pressure drop exceeding 20 mmHg upon standing. Cardiovascular and neurological examinations were otherwise normal. Laboratory tests, including renal function and electrolyte levels, were within normal limits. A structured medication review identified diazepam and gabapentin as likely contributors to the patient's symptoms.

Originality: This case illustrates how recurrent falls may represent a medication-related adverse effect rather than a primary

neurological or cardiovascular disorder, emphasizing the diagnostic value of systematic medication review in primary care.

Lessons learned and future implications: Deprescribing centrally acting medications in older adults can significantly improve safety and functional outcomes. Primary care–based medication review should be routine in elderly patients presenting with falls or dizziness.

Discussion: Benzodiazepines and gabapentinoids are well known to increase fall risk through sedation and impaired postural reflexes. Addressing polypharmacy at the primary care level can reduce preventable harm.

Conclusion: Benzodiazepines and gabapentinoids are well known to increase fall risk through sedation and impaired postural reflexes. Addressing polypharmacy at the primary care level can reduce preventable harm. Keywords (MeSH, plain text): Primary Care, Family Medicine, Polypharmacy, Falls, Orthostatic Hypotension, Older AdultsKeywords (MeSH, plain text): Primary Care, Family Medicine, Polypharmacy, Falls, Orthostatic Hypotension, Older Adults

(1) Department Of Family Medicine, Dokuz Eylul University Faculty Of Medicine, İzmir, Türkiye
(2) Department Of Fam .prof. Dr Ily Medicine, Dokuz Eylul University Faculty Of Medicine, İzmir, Türkiye

Context: Nephrotic syndrome, characterized by heavy proteinuria, hypoalbuminemia, edema, and hypertension, represents a potentially serious renal condition that may first be encountered in primary care. Membranous glomerulonephritis (MGN) is one of the most common causes of nephrotic syndrome in adults and can present without overt systemic symptoms. Early recognition in family medicine is essential to prevent complications and enable timely specialist referral.

Methods: A 26-year-old woman presented to a primary care clinic with a two-month history of bilateral eyelid swelling, progressive lower extremity edema, and reduced urine output. She had no known chronic disease, no regular medication use, and no family history of renal disease. Physical examination revealed marked bilateral periorbital edema, severe pitting edema of the lower extremities, diffuse hyperpigmented skin lesions, and elevated blood pressure (170/100 mmHg). Given the combination of persistent edema and hypertension, the patient was urgently referred to a tertiary care center for further evaluation. One month later, the patient returned with discharge documentation. Investigations demonstrated nephrotic-range proteinuria (>6 g/day), hypoalbuminemia, and normal renal serology, including negative anti-dsDNA antibodies and normal complement levels. There was no history of non-steroidal anti-inflammatory drug use or systemic symptoms suggestive of secondary causes. Renal biopsy confirmed the diagnosis of primary membranous glomerulonephritis.

Originality: This case highlights how subtle but persistent clinical findings in a young patient can indicate severe renal pathology and underscores the diagnostic value of vigilant assessment in primary care.

Lessons learned and future implications: Persistent edema and hypertension in young adults should prompt consideration of glomerular disease. Early referral for advanced diagnostics, including renal biopsy, is critical.

Discussion: MGN may present insidiously, and primary care physicians play a key role in initiating timely evaluation and referral, enabling early immunosuppressive treatment.

Conclusion: Family physicians are central to the early detection of nephrotic syndrome. Clinical vigilance and prompt referral can significantly influence patient outcomes in serious renal disease. Keywords (MeSH, plain text): Nephrotic Syndrome; Membranous Glomerulonephritis; Primary Care; Proteinuria; Renal Biopsy

ID 765- Assessment of the impact of fatty acids in patients with rheumatoid arthritis

Nina JHITA, Vincent SAI, Mina GUPTA, Tom RATCLIFFE, Ryan BELL

Modality Partnership, Nationwide, Royaume-Uni

Context: Primary care teams worldwide face increasing administrative pressure alongside growing demand and workforce shortages. Intelligent automation—often referred to as Robotic Process Automation (RPA)—can streamline routine, rule-based tasks and release time for patient care. This workshop introduces system-neutral, transferable principles for adopting automation safely and effectively in diverse international settings. Across many countries, clinicians and administrative teams spend substantial time on repetitive tasks such as filing results, handling prescriptions, routing documents and updating records. This reduces capacity for direct care and contributes to burnout. Automation offers a method for supporting overstretched teams, even in low-resource environments, by targeting predictable workflows that do not require clinical judgement. Drawing on practical implementation experience, this workshop focuses on identifying suitable tasks, preparing teams for change and establishing safe, reliable processes.

Objectives: Participants will be able to: 1. Understand the role of automation in primary care and its limitations. 2. Identify key criteria for selecting tasks suitable for automation in any health system. 3. Apply a structured approach to piloting and scaling automation. 4. Recognise essential governance, safety and workforce considerations. 5. Reflect on how automation could support their own local context.

Teaching method and workshop: Short presentations on workflow selection, governance and international use cases. Interactive Mentimeter activity where participants vote on which administrative tasks could be automated within their own settings. Small-group reflection on results, discu

Expected outcomes: Participants will gain a practical framework for evaluating automation opportunities, understanding safety considerations and engaging staff. They will leave with transferable strategies to begin exploring or refining automation within their own environme

Conclusion: This workshop offers a concise, practical and internationally adaptable introduction to administrative automation in primary care, supporting delegates to reduce burden and improve sustainability within their own systems.

ID 1163- Assessment of the incidence of scabies in primary care and its associated pharmacological load.

Nina JHITA, Vincent SAI, Mina GUPTA, Tom RATCLIFFE, Ryan BELL

Modality Partnership, Nationwide, Royaume-Uni

Context: Administrative workload in primary care has grown substantially, with clinical and non-clinical teams spending large amounts of time on repetitive tasks such as prescription processing, results handling, document workflows and routine data entry. These pressures limited capacity for proactive patient care and contributed to delays, variation and staff fatigue. Practices sought an at-scale solution to reduce low-value work and improve the working day while supporting safe, timely operations.

Methods: An innovative, structured programme of intelligent automation was introduced across multiple primary care sites serving approximately 500,000 patients. Systematic review of clinical and non-clinical administrative workflows across all practices identified processes that were: • High volume • Highly repetitive • Rule-based • Safety-sensitive, but amenable to automation with robust governance • Likely to free capacity More than thirty workflows were selected across prescriptions, pathology routing,

document handling, registration workflows and administrative triage. Each process was mapped collaboratively with staff, ensuring the automation reflected real operational nuance. Transparent communication and early demonstrations of effective processing helped build trust. Safety checks were embedded at critical points and concerns about clinical safety addressed in DTAC, DPIA and DCB0129/0160-aligned safety assessment. Potential for unchecked errors was addressed through meticulous planning, strict governance, exception reporting and robust clinical monitoring. Strengths included rapid impact and the ability to scale once a workflow was proven safe.

Originality: The programme differed from typical digital interventions by creating a cross-cutting automation layer that supported numerous workflows simultaneously. It was not a single-tool implementation but a systematic redesign of how administrative work flowed through the organisation.

Lessons learned and future implications: Starting with simple, stable workflows built confidence and generated early wins. Staff reported substantial relief as thousands of repetitive actions were absorbed by automation, allowing more time for patient-facing and complex tasks. Future work includes expanding automation into clinical correspondence and population-health processes.

Discussion: Selecting workflows based on volume, predictability and safety ensured automation enhanced—rather than disrupted—daily practice. Collaboration with frontline staff proved essential.

Conclusion: The intelligent automation programme significantly reduced administrative burden releasing of 55,000 hours of staff time, equivalent to 30 WTE clinicians. This offers a transferable framework for modernising primary care operations.

ID 2169- Association between Early Post-Diagnosis Physical Activity in Reducing Dementia Risk Among Patients with New-Onset Depression

Buğra BALCAN, Alperen KÜÇÜKUYSAL, Vildan MEVSIM

Department Of Family Medicine, Dokuz Eylul University Faculty Of Medicine, Izmir, Turkey, İzmir, Türkiye

Context: Acute scrotal pain is a time-critical emergency, but adolescents may present with non-specific lower abdominal pain, leading to delays in examination and referral in busy primary care clinics.

Methods: A 14-year-old boy presented to a FHC with sudden left lower abdominal pain and nausea for six hours. He denied diarrhea or urinary symptoms and felt embarrassed to discuss genital complaints. Vital signs were stable; abdominal examination showed mild left lower quadrant tenderness without guarding. Because of pain severity and the absence of gastrointestinal symptoms, a brief, respectful genitourinary history was revisited. The patient then disclosed that the pain “started in the testis and moved up.” A focused scrotal examination (with consent and a chaperone) revealed a high-riding, tender left testis and absent cremasteric reflex. Suspecting testicular torsion, the physician arranged immediate transfer to the nearest urology-capable emergency department, advising nil by mouth and explaining urgency to the family. The receiving team performed urgent surgery confirming torsion; detorsion and orchiopexy were completed, and the testis was viable. Contralateral fixation was also done. At FHC follow-up, the patient and parents reflected that embarrassment nearly delayed care. Education was provided on seeking urgent help for any acute scrotal pain.

Originality: The case highlights how deliberate, consent-based examination can uncover hidden red-flag conditions in adolescents.

Lessons learned and future implications: Primary care teams should normalize confidential questions for adolescents and keep a low threshold for genital examination when abdominal pain is unexplained.

Discussion: Torsion is primarily a clinical diagnosis; delays reduce salvage rates. Clear communication and a chaperoned exam protect both patient safety and trust.

Conclusion: In FHC practice, unexplained acute lower abdominal pain in boys should prompt consideration of testicular torsion and urgent referral.

ID 187- Association between Frailty Index and the Risk of Mortality and ICU Admission in Older Adults: A Nationwide retrospective study based on Long-Term Care Insurance Database

Ula CHETTY, Lynsey YEOMAN, Aliki TRAIANOU, Kelly BALDEON CUENCA

University Of Glasgow, Glasgow, Royaume-Uni

Context: General Practice is under significant strain from an aging population, multimorbidity, marked under-resourcing and increased waiting lists post COVID pandemic. Secondary care faces similar pressures, resulting in a growing number of rejected referrals. Multisystem, complex conditions are being redirected to GPs who may lack specialist training in the diagnosis and management of them. Examples include suspected hypermobile Ehlers-Danlos syndromes, fibromyalgia and postural orthostatic tachycardia syndrome.

Objectives: To identify common conditions and issues are being frequently rejected by secondary care across Europe. Explore and share how GPs are managing these challenges in practice.

Teaching method and workshop: This workshop will begin with a short presentation outlining the context and real-world examples, followed by interactive roundtable discussions. Participants will discuss experiences and strategies from their respective countries.

Expected outcomes: This workshop will produce a summary of Pan-European challenges and insights on the rising remit of family doctors, which will inform future research and is intended for publication.

Conclusion: Rejected referrals are not isolated incidents and they represent a growing systemic challenge across Europe. GPs are innovating under pressure but the lack of structured training and resources for complex multisystem conditions represents a crucial gap. Pan-European collaboration is essential to share strategies, develop guidance and advocate for the realistic boundaries of primary care.

ID 1526- Association between low phase angle scores and cardiovascular disease risk factors

Mina GUPTA [(1)], Vincent SAI [(1)], Grace GIMSON [(2)], Tom RATCLIFFE [(1)], Nina JHITA [(1)]

(1) Modality Partnership, Nationwide, Royaume-Uni
(2) Holly Health, Nationwide, Royaume-Uni

Context: Across many countries, primary care teams are experiencing rising demand linked to stress, anxiety, sleep disturbance, low mood and lifestyle-related conditions. Digital self-management tools can help patients build healthier routines, improve emotional wellbeing and reduce reliance on reactive care. This workshop introduces practical, transferable strategies for implementing digital wellbeing tools in a wide range of international primary care settings. Globally, wellbeing-related concerns are among the most common reasons patients seek primary care. These issues often coexist with multimorbidity, social stressors and chronic conditions, creating frequent appointments and placing sustained pressure on clinical teams. Many systems have limited capacity for structured psychological support or behavioural interventions, making it difficult to offer continuity between consultations. Digital self-management tools offer a scalable means of supporting patients outside traditional appointments through personalised prompts, behavioural nudges and structured reflection. They can strengthen patient autonomy, reduce avoidable consultations and shift care from reactive to

preventative without requiring high-resource infrastructure. Adaptable onboarding, hybrid support for digitally excluded groups and integration with existing workflows make these tools viable across low-, middle- and high-income settings. This workshop focuses on how primary care teams can safely and effectively implement these tools in their own context.

Objectives: Participants will be able to: 1. Understand essential components of digital self-management tools. 2. Identify suitable patient groups and referral criteria. 3. Integrate tools within primary care workflows. 4. Support digital inclusion through structured onboarding and hybrid pathways. 5. Adapt implementation strategies to varying technological and cultural environments.

Teaching method and workshop: Short presentations on behavioural change, patient activation and workflow integration. Mentimeter activity: delegates vote on the wellbeing challenges most affecting their populations. Small-group discussion exploring implementation barriers and enablers

Expected outcomes: Participants will gain an adaptable framework for implementing digital wellbeing support, improving patient self-management and reducing avoidable demand.

Conclusion: This workshop provides a practical, context-sensitive roadmap for integrating digital self-management tools into primary care, enabling delegates to improve wellbeing support and enhance system sustainability.

Duygu AYHAN BASER, Hande KONSUK UNLU

Hacettepe University Faculty Of Medicine, Ankara, Türkiye

Context: Climate change poses growing challenges to health systems worldwide, with significant implications for primary care. Rising temperatures, extreme weather events, air pollution, and ecological changes are altering disease patterns and increasing the burden of climate-sensitive conditions. As the first point of contact in healthcare, family medicine plays a critical role in responding to these emerging health threats.

Objectives: This systematic review aims to synthesize existing evidence on the impact of climate change on family medicine practices, focusing on clinical workload, service delivery, preventive care, and professional roles.

Methods: A systematic literature search was conducted in PubMed, Scopus, and Web of Science following PRISMA guidelines. Peer-reviewed studies examining the effects of climate change on family medicine or primary care settings were included. Data were synthesized thematically to identify key challenges, practice implications, and response strategies.

Results: The reviewed studies indicate that climate change is associated with increased presentations of respiratory, cardiovascular, infectious, and mental health conditions in primary care. Family physicians face growing workloads, service disruptions during extreme weather events, and expanding responsibilities in risk communication and prevention. However, evidence on structured adaptation strategies and climate-informed practice models remains limited.

Discussion: This review demonstrates that climate change is increasingly shaping the scope and workload of family medicine through climate-sensitive diseases, service disruptions, and preventive care demands. However, evidence on practical implementation remains limited. Integrating climate-informed education, preparedness frameworks, and policy support into primary care is essential to strengthen the resilience of family medicine practices.

Conclusion: Climate change is increasingly influencing the scope and demands of family medicine practice. Strengthening climate-informed education, preparedness, and policy integration within primary care is essential to enhance the resilience and sustainability of family medicine in the face of climate-related health risks.

Duygu AYHAN BASER [1] , Sule GÜMÜSTAKIM [2]

(1) Hacettepe University Faulty Of Medicine, Ankara, Türkiye
(2) Kahramanmaras Sutcu Imam University, Kahramanmaraş, Türkiye

Context: Family medicine inherently requires a multidisciplinary perspective; however, translating this approach into academic research and scholarly collaboration remains challenging. Multidisciplinary academic studies—bringing together family physicians with researchers from public health, nursing, psychology, sociology, health economics, and other disciplines—are increasingly recognized as essential for addressing complex health problems and strengthening primary care research capacity.

Objectives: This literature review aims to examine the scope, characteristics, and contributions of multidisciplinary academic research in family medicine, with a focus on research themes, collaborative structures, and academic outcomes.

Methods: A narrative literature review was conducted using PubMed, Scopus, and Web of Science. Peer-reviewed studies describing multidisciplinary or interprofessional academic research conducted in family medicine or primary care settings were included. The literature was thematically analyzed in terms of disciplinary composition, research focus, and reported academic and system-level impacts.

Results: The literature demonstrates that multidisciplinary academic collaborations in family medicine contribute to more comprehensive research questions, methodological diversity, and higher translational relevance. Common research areas include chronic disease management, preventive care, health services research, medical education, and community-based interventions. Key facilitators include institutional support, shared research frameworks, and mutual disciplinary respect, while barriers include role ambiguity, differences in academic culture, and limited structural incentives.

Discussion: The findings highlight that multidisciplinary academic collaboration enhances methodological rigor and translational relevance in family medicine research. However, sustainable collaboration requires clear role definitions, institutional support, and academic incentive structures. Strengthening interprofessional research training may further advance the academic capacity and global visibility of family medicine.

Conclusion: Multidisciplinary academic research strengthens the scientific foundation and societal impact of family medicine. Supporting collaborative research structures and fostering interprofessional academic networks are crucial for advancing primary care scholarship and addressing complex health challenges.

Department Of Family Medicine, Dokuz Eylul University Faculty Of Medicine, Izmir, Turkey, İzmir, Türkiye

Context: Headache is common after childbirth and may be attributed to sleep deprivation. Yet postpartum hypertension and delayed preeclampsia can emerge after discharge and require rapid recognition in first-contact primary care.

Methods: A 32-year-old woman, 10 days after an uncomplicated vaginal delivery, attended a FHC with sudden severe frontal headache and blurred vision since the previous night. She denied fever and had no migraine history. On triage her BP was 168/112 mmHg, pulse 92/min, temperature normal. Focused neurological examination was non-focal. Urine dipstick in the clinic showed 2+ protein. The

combination of postpartum status, severe headache, hypertension, and proteinuria raised concern for postpartum preeclampsia. The patient was advised to avoid driving, was given clear safety-netting (seizure, worsening vision, chest pain, dyspnea), and was urgently referred to the emergency department with a written note. Hospital evaluation confirmed postpartum preeclampsia; magnesium sulfate and antihypertensive therapy were started. At FHC follow-up two weeks later, BP was controlled, symptoms had resolved, and she received counseling on home BP monitoring and warning signs for recurrence.

Originality: This case shows how basic measurements available in FHC settings can trigger life-saving referral decisions

Lessons learned and future implications: Postpartum headache should be treated as a red-flag symptom until BP is checked. A short "postpartum red-flag" triage checklist can reduce missed cases.

Discussion: Delayed postpartum preeclampsia may present subtly and is easy to mislabel as normal postpartum fatigue. Continuity in family medicine supports follow-up and prevention.

Conclusion: Delayed postpartum preeclampsia may present subtly and is easy to mislabel as normal postpartum fatigue. Continuity in family medicine supports follow-up and prevention

Context: Pruritus is a frequent and often benign complaint in family medicine. Nevertheless, when symptoms persist or evolve particularly in older patients with complex medical backgrounds they may reflect serious underlying disease. This case illustrates the value of thorough anamnesis, repeated physical examination, and continuity of care in primary practice.

Methods: A 79 year-old man, well known to his family physician, with type 2 diabetes mellitus and stable chronic myelomonocytic leukemia (CMML), presented following recovery from herpes zoster with persistent pain and severe pruritus. Initial assessment was consistent with postherpetic neuralgia. Through ongoing visits, careful anamnesis revealed progression in symptom severity and character. Repeated physical examinations over time identified evolving erythematous, flat, scaly lesions on the back, thighs, and later the arms. Despite multiple specialist consultations, family medicine maintained longitudinal responsibility integrating fragmented information, reassessing working diagnoses, and advocating for further investigation. Examination revealed red-brown, flat to slightly raised lesions with sharp yet irregular borders, dry and scaly, without systemic involvement. Skin biopsy was eventually performed.

Originality: While mycosis fungoides is known to mimic benign dermatoses, this case is distinctive due to its initial presentation following herpes zoster, which obscured the diagnosis. Unlike many reports arising solely from dermatology settings, this diagnosis emerged through continuous observation in primary care, highlighting the unique contribution of family medicine.

Lessons learned and future implications: Family physicians should reassess persistent pruritus through repeated anamnesis and examination. Avoid premature diagnostic closure, ensure follow-up continuity, and attend to subtle symptom evolution, especially when complaints persist despite expected recovery.

Discussion: Ongoing follow-up enabled recognition of evolving clinical patterns beyond isolated symptoms. Careful attention to the patient's narrative and clinical judgment was central to identifying deviation from the expected clinical course.

Conclusion: This case highlights family medicine's capacity to uncover serious disease behind common symptoms through continuity, attentive anamnesis, repeated physical examination, and holistic clinical reasoning, while addressing patients' bio-psycho-social needs throughout the diagnostic and therapeutic journey.

Trakya University, Department Of Family Medicine, Edirne, Türkiye

Context: One Health, Planetary Health, and Sustainability are increasingly described as the bedrock of modern family medicine, particularly within the WONCA framework. These approaches aim to address complex global challenges by integrating human, animal, environmental, and system-level perspectives. However, as these principles gain prominence, an important question emerges regarding how consistently these global health frameworks enhance patient safety and quality of care, and how much they contribute to patient-centered practice in real-world implementation. Family medicine, positioned at the interface between individual care and population health, is uniquely affected by this tension.

Objectives: A key objective is to clarify the interaction between the bedrock of WONCA tree and the clinical approach in family medicine. Thus, this workshop aims to critically examine whether the WONCA bedrock effectively serves in family doctors' daily practice. Participants will explore: How these principles can improve patient care, Where they may introduce ethical, clinical, or organizational risks, How a balance can be maintained between global responsibilities and patient-centered care. How to apply the bedrock principles in the real world.

Teaching method and workshop: This interactive workshop uses a case-based and reflective learning design. After a brief framing introduction, participants work with a single complex family medicine case examined through three lenses: One Health, Planetary Health, and Sustainability. S

Expected outcomes: Participants will develop the ability to: Critically appraise the application of One Health, Planetary Health, and Sustainability in clinical practice, Recognize situations where these frameworks enhance care and where they may pose risks, Apply a patient

Conclusion: This workshop discusses how the WONCA bedrock strengthens family practice through appropriate support for the principles of family medicine, including patient-centeredness, continuity, comprehensiveness, coordination, and safety.

Context: Falls are a leading cause of injury, hospitalization, and loss of independence in adults aged ≥65. Multifactorial interventions targeting physical, environmental, and medical risk factors are effective in reducing falls.

Objectives: To synthesize recent evidence on fall prevention strategies for adults ≥65 and provide guidance for clinical and community implementation.

Methods: A literature search was conducted in PubMed in December 2025 using the keywords "Prevention of Falls" and "Older Adults," limited to studies published within the past five years and involving adults aged 65 years and older. Randomized controlled trials, cohort studies, meta-analyses and systematic reviews were included.

Results: Exercise and balance programs (e.g., balance-focused training using Huber stabilizer and C-mill simulators, gait-based balance exercises, Tai Chi)improve strength, gait and postural control, reducing fall risk.Environmental interventions such as ,nonslip socks and home hazard modifications, enhance safety in community-dwelling older adults.Risk prediction tools (nomograms for frail and pre-frail adults) allow individualized prevention strategies. Medical factors, including vision impairment and comorbidities, contribute to falls, highlighting the need for comprehensive evaluation. Healthcare engagement, including annual wellness visits, improves fall prevention and reduces fractures. Family-centred, nurse-led home modification interventions have been associated with reduced falls in community-dwelling older adults.

Discussion: Multifactorial interventions combining exercise, environmental modifications, and risk-based medical management are most effective.Primary care physicians, who are able to assess individuals together with their family and home environment and maintain continuous contact with patients, are in a unique and strong position to identify risks and provide preventive strategies and counseling

Conclusion: Individualized, multifactorial strategies effectively reduce falls among older adults. Implementing these interventions in clinical and community settings can enhance independence, decrease healthcare burden, and improve quality of life.

ID 266- Association of multimorbidity clusters with adverse health outcomes: analysis of data from CHARLS

Yakup Batuhan TUNA, Elifnaz TUNA, Yasemin ÖZKAYA, Bakiye Nurdan TEKGÜL, Umut GÖK

University Of Health Science İzmir City Hospital, İzmir, Türkiye

Context: Vitamin D deficiency is common in older adults and associated with such as falls, fractures, reduced muscle strength, and functional decline. Globally, the rapidly increasing population aged 80 years and older is characterized by frailty, multimorbidity.Vitamin D deficiency risk is increased by reduced sun exposure, limited mobility, nutritional inadequacy, polypharmacy, and social inequalities. In our country, despite the inability to routinely measure vitamin D levels in primary care and the frequent prescription of vitamin D at prophylactic doses, uncertainties persist regarding optimal serum threshold values and the appropriateness of routine supplementation in elderly populations. Social disadvantages makes it essential to clarify the existing evidence in order to support equitable, humanistic, and patient-centered decision-making in family medicine.

Objectives: The aim of this review is to evaluate current evidence on vitamin D levels and prophylactic supplementation in frail adults aged 80 years and older in order to support evidence based and patient centered decision making in primary care.

Methods: A literature review was conducted using PubMed. Articles published within the last five years were identified using the keywords "vitamin D" OR "25-hydroxyvitamin D" AND "aged 80 and over." Review and systematic review studies were included.

Results: The reviewed literature reports a high prevalence of vitamin D deficiency among adults aged 80 years and older.Evidence supporting routine vitamin D supplementation inconsistent. Some reviews report potential benefits of supplementation in selected high-

risk and frail subgroups, such as individuals with osteoporosis, previous falls or fractures, limited outdoor activity.In contrast, routine supplementation has not demonstrated consistent improvements in clinically meaningful outcomes.

Discussion: Clarifying current evidence is essential to support equitable, humanistic, and patient-centered decision-making in family medicine.

Conclusion: Current evidences do not support routine supplementation for all patients in this group.Therefore, decisions regarding vitamin D supplementation should be guided by individual risk profiles rather than routine practice. Vitamin D levels below 20 ng/mL indicate deficiency, while levels ≥20–30 ng/mL are generally considered sufficient, with ≥30 ng/mL in frail older adults. Supplementation with 800–1000 IU/day is commonly recommended.Individualized dosing based on clinical risk factors and serum monitoring remains essential in this group.

ID 300- Association of the pulmonary artery–aorta ratio with clinical outcomes in acute exacerbations of COPD: implications for primary care

Atanur AYAS, Yasemin OZKAYA, Bakiye Nurdan TEKGUL

Izmir City Hospital, Izmir, Türkiye

Context: Adolescence is a developmentally sensitive period characterized by identity formation, emotional fluctuation, and an increasing need for autonomy and belonging. Psychosocial distress during this stage rarely presents with clear psychiatric symptoms; instead, it often manifests through early signals such as emotional withdrawal, reduced communication, academic difficulties, and social isolation. Family physicians, through continuity of care and a biopsychosocial perspective, are uniquely positioned to recognize these warning signs before they reach diagnostic thresholds. The TV series Adolescence offers a metaphorical portrayal of how adolescents' emotional burdens and environmental stressors may remain unnoticed until they escalate to a crisis.

Objectives: To discuss the preventive role of listening and understanding in family medicine practice before the onset of adolescent mental disorders, using Adolescence as a metaphorical and awareness-raising framework rather than a clinical case presentation.

Methods: This study is a narrative and reflective review grounded in the biopsychosocial model of primary care. Relevant literature on adolescent mental health and the HEEADSSS psychosocial assessment framework was reviewed. Selected scenes from the TV series were used solely as fictional and non-diagnostic metaphors to illustrate unmet emotional needs, family communication difficulties, peer exclusion, and delayed responses within home and school environments.

Results: The metaphorical narrative demonstrates that adolescents often express distress indirectly through silence, behavioral changes, and disengagement rather than explicit help-seeking. Scenes depicting family communication breakdown, peer bullying, and social exclusion closely parallel early psychosocial signals commonly encountered in primary care settings.

Discussion: In family medicine practice, non-judgmental listening, protection of confidentiality, and longitudinal follow-up facilitate early recognition of psychosocial vulnerability. The HEEADSSS framework provides a structured approach to identifying risk areas before pathology emerges. Cultural narratives can enhance professional awareness by illustrating the consequences of missed preventive opportunities.

Conclusion: Family physicians play a key preventive role in adolescent mental health by listening before labeling and intervening before pathology develops. Early, trust-based communication remains one of the most effective preventive strategies in primary care.

ID 1725- Associations Between Global Cancer and Screening Test Search Behaviors, Epidemiological Indicators, and the Human Development Index: An Ecological Study Using Google Trends

Gretchen ABUENA

Southern Isabela Medical Center, Santiago City, Philippines

Context: Chronic Obstructive Pulmonary Disease (COPD) remains underdiagnosed in the Philippines despite its high prevalence and mortality. Smoking continues to be the leading risk factor, compounded by environmental exposures such as biomass fuel use and limited access to health services, especially in geographically isolated and disadvantaged areas (GIDA). This case highlights the clinical, psychosocial, and family dimensions of COPD in a heavy smoker and underscores the importance of holistic, family-centered care.

Methods: This case presentation utilized a comprehensive family medicine approach. Data were gathered through detailed history taking, physical examination, diagnostic tests, family assessment tools (genogram, family APGAR, SCREEM, lifeline, eco-map), and counseling sessions. Clinical evaluation was supported by spirometry, imaging, and laboratory tests. Patient-centered education, counseling, and family involvement were emphasized to address medical, psychosocial, and economic concerns.

Originality: The uniqueness of this case lies in its integration of clinical management with a biopsychosocial and family-oriented framework. Beyond diagnosing very severe COPD, the case demonstrates how family dynamics, cultural beliefs, economic limitations, and health literacy significantly influence disease perception, adherence, and outcomes. The use of community and government support systems further illustrates practical continuity of care in a rural setting.

Lessons learned and future implications: Early identification of COPD risk factors, clear communication, and continuous education are vital. Addressing emotional distress, cultural beliefs, and socioeconomic barriers enhances patient acceptance and compliance. Family involvement strengthens long-term disease management.

Discussion: The patient's long smoking history, biomass exposure, and delayed diagnosis contributed to disease progression. Misconceptions regarding heredity initially affected health-seeking behavior. Through effective clinician–patient–family engagement, these beliefs were corrected, leading to improved insight, smoking cessation, and treatment adherence. Family support emerged as a key protective factor, while financial and access barriers required coordination with local resources.

Conclusion: COPD management extends beyond pharmacologic treatment. A holistic, family-centered, and community-linked approach is essential in improving quality of life, preventing exacerbations, and empowering patients—particularly in underserved communities.

Clalit Health Care Services And Hebrew University, Jerusalem, Israël

Context: Clinical reasoning is a core competency in family medicine but is often assumed rather than explicitly taught. Family physicians routinely manage undifferentiated presentations under conditions of uncertainty and time pressure. While trainees receive frequent feedback on clinical decisions, much less attention is given to the reasoning processes behind those decisions. Consequently, cognitive biases affecting both learners and supervisors may go unrecognized. Teaching clinical reasoning requires making clinical thinking explicit and central to everyday supervision in primary care.

Objectives: By the end of this workshop, participants will be able to: Identify common cognitive biases in family medicine practice .Use practical, time-efficient strategies to teach clinical reasoning in real time. Supervise trainees with an explicit focus on reasoning rather than solely on outcomes.

Teaching method and workshop: This 60-minute interactive workshop uses experiential learning methods suited to busy primary care settings. The session begins with a brief clinical case presented in plenary, followed by participant discussion of immediate diagnostic impressions to high

Expected outcomes: Participants will gain increased awareness of cognitive bias and practical tools to teach clinical reasoning during routine supervision.

Conclusion: Clinical reasoning is a teachable skill. Focusing supervision on thinking processes rather than answers promotes deeper, more reflective clinical practice.

Context: Physician advocacy is a core professional competency, yet many practitioners feel unequipped due to a lack of formal training and systemic barriers. The COVID-19 pandemic and heightened awareness of social inequities have intensified the need for physicians to advocate for their patients and public health policies. This presentation addresses the gap between this professional expectation and practical readiness.

Methods: Physician advocacy is a core professional competency, yet many practitioners feel unequipped due to a lack of formal training and systemic barriers. The COVID-19 pandemic and heightened awareness of social inequities have intensified the need for physicians to advocate for their patients and public health policies. This presentation addresses the gap between this professional expectation and practical readiness.

Originality: This program moves beyond theory to offer a replicable, skills-based framework. Its originality lies in a holistic, action-oriented approach that demystifies advocacy. By combining simulated legislative, written, and media communication, it provides the confidence and tools to translate clinical insights into action, reframing advocacy as a manageable professional intervention.

Lessons learned and future implications: The program is highly sought after, with participants actively engaging in advocacy and publishing their work. This proves that structured training helps physicians overcome perceived barriers. The key implication is that integrating practical advocacy training into medical education and continuing professional development is essential for creating physician-advocates who can drive health policy reform.

Discussion: This model's success highlights a critical need. While physicians have the passion and knowledge to be powerful advocates, they often lack specific communication skills for policy and media engagement. This curriculum effectively bridges that gap, providing a clear pathway from clinical concern to public influence and confirming that barriers like unfamiliarity are surmountable with targeted education.

Conclusion: "Prescribing Change" offers a proven model to empower trainees and physicians, transforming them from observers to active agents of systemic change. It provides a practical guide enabling them to use their unique voice to shape a healthier, more equitable future.

Dokuz Eylul University, Faculty Of Medicine, Department Of Family Medicine, Izmir, Türkiye

Context: Acute pancreatitis is a common cause of acute abdominal pain and may result in significant morbidity if diagnosis is delayed. In first-contact care settings, including emergency departments serving as initial points of access, early diagnosis can be challenging. Atypical symptom presentation, limited access to key laboratory tests, and low sensitivity of early imaging may lead to premature diagnostic exclusion. This case highlights the risks of early exclusion of acute pancreatitis and the importance of reassessment when symptoms evolve.

Methods: A 21-year-old underweight male presented with a one-week history of progressive postprandial back pain, more prominent in the evenings and absent in the mornings. He denied alcohol use, vomiting, changes in stool or urine color. Family history was notable for gallstone disease. Physical examination revealed a soft, non-tender abdomen without guarding or jaundice. Initial laboratory tests showed mildly elevated serum amylase, total bilirubin of 1.5 mg/dL, elevated C-reactive protein (≈25 mg/L), and a normal complete blood count. Serum lipase testing was unavailable. Abdominal ultrasonography revealed no abnormalities. As diagnostic criteria for acute pancreatitis were not met, conservative management was initiated. Symptoms improved within 12 hours, and the patient was discharged with clear safety-netting advice. Two days later, the patient re-presented with recurrent abdominal pain. Computed tomography demonstrated findings consistent with acute pancreatitis. Serum lipase measured after referral was markedly elevated (890 U/L), confirming the diagnosis. Biliary causes were excluded, and autoimmune pancreatitis was considered retrospectively.

Originality: This case highlights a diagnostic challenge in emergency care, where limited access to key laboratory tests and early negative imaging may lead to premature exclusion of acute pancreatitis.

Lessons learned and future implications: Persistent or recurrent symptoms should prompt reassessment, even when initial findings are inconclusive. Robust safety-netting and clinical vigilance are essential in diagnostic uncertainty.

Discussion: This case illustrates the limitations of first-contact care, where restricted access to lipase testing and low sensitivity of early imaging may obscure evolving acute pancreatitis. Mild enzyme elevation and transient symptom improvement may provide false reassurance.

Conclusion: Acute pancreatitis may be missed at first presentation in first-contact care. Awareness of evolving clinical patterns and timely reassessment are critical to prevent delayed diagnosis and adverse outcomes.

ID 1711- Atypical non–ST elevation myocardial infarction presenting with dizziness and severe hypertension

Alperen KÜÇÜKUYSAL, Zeynep PEKEL, Vildan MEVSIM

Dokuz Eylul University, Faculty Of Medicine, Department Of Family Medicine - Izmir (Türkiye), Izmir, Türkiye

Context: Family physicians are often the first health professionals to encounter signs that may suggest child abuse. In rural settings, where social relationships are closely intertwined and access to specialist support is limited, distinguishing between pathological findings and normal variants presents significant ethical and clinical challenges. Managing diagnostic uncertainty while protecting both the child and the family relationship requires careful judgment.

Methods: During my first year working as a family physician in a small rural clinic, a 15-year-old boy attended a routine visit accompanied by his father. Physical examination revealed multiple horizontal, linear marks on the upper back. Given their appearance, the possibility of physical abuse needed to be considered. The

adolescent was tall and lean, with no additional findings suggestive of systemic or endocrine disease. To ensure a safe and confidential assessment, the father was asked to leave the room, and the adolescent was interviewed alone. He appeared calm, denied any harm, and provided consistent responses. With the father's consent, clinical photographs were taken. Subsequent review of dermatological resources identified the lesions as physiological striae distensae, commonly seen during rapid growth. This interpretation was supported by the patient's body habitus and history. Findings were explained transparently to both the patient and his father, which reduced anxiety and restored trust.

Originality: This reflection addresses a common but under-discussed dilemma in rural primary care: managing child protection concerns when clinical findings fall into a diagnostic grey zone.

Lessons learned and future implications: Slowing down clinical reasoning, questioning assumptions, consulting objective sources, and ensuring private adolescent interviews are essential. Respectful communication and careful documentation help balance vigilance with fairness.

Discussion: In primary care, ethical decision-making often involves uncertainty. Reflective practice and structured assessment are crucial to avoid both missed harm and unwarranted accusations, particularly in resource-limited settings.

Conclusion: Child protection in family medicine requires a delicate balance between safeguarding vulnerable patients and maintaining trust. Thoughtful reflection and transparent communication enable ethical and professional management of uncertainty.

ID 835- Atypical Presentation of Acute Coronary Syndrome in a Primary Care Setting: A Diagnostic Challenge

Ibtissem SAAD SAOUD

Department Of Endocrinology / Internal Medicine, Central Military Hospital Dr. Mohamed Seghir Nekkache, Alger, Algérie

Context: Primary aldosteronism (PA) is an underdiagnosed cause of secondary hypertension in primary care settings. Beyond increased blood pressure, patients with PA often exhibit metabolic disturbances including obesity, dyslipidaemia, and impaired glucose regulation. These abnormalities aggregate as metabolic syndrome (MetS), a significant contributor to cardiovascular morbidity and mortality. For ordinary care physicians, identifying metabolic patterns in hypertensive patients may enable earlier detection of primary aldosteronism and enhance cardiovascular risk assessment.

Objectives: To evaluate the prevalence of MetS among patients with PA and to examine the relationship between aldosterone excess and specific metabolic components related to primary care practice.

Methods: We performed a retrospective observational study involving patients diagnosed with PA between 2020 and 2022. Demographic information (age and gender), personal and family medical histories, and diagnostic circumstances were gathered. Clinical and biochemical parameters covered age at disease onset, hypertension degree, serum potassium concentrations, and the renin–aldosterone ratio (RAR). Medical and surgical treatment methods were recorded. Metabolic parameters involved body mass index (BMI), fasting glucose concentrations, and lipid profile. MetS was characterized in accordance with the criteria established by the National Cholesterol Education Program Adult Treatment Panel III (NCEP-ATP III). Ethical approval was obtained

Results: Twenty-one patients diagnosed with PA were enrolled, all of whom presented with hypertension. Based on BMI, 33.3% of patients were classified as obese, while 28.6% were

categorized as overweight. Impaired glucose metabolism, characterized by diabetes mellitus or anomalous fasting glucose levels, was identified in 28.6% of patients, while 19.0% exhibited dyslipidaemia. Serum potassium levels were within the normal range in 61.9% of cases. The renin–aldosterone ratio was elevated in all patients. Based on NCEP-ATP III criteria, MetS was diagnosed in six patients (28.6%).

Discussion: The general co-occurrence of obesity and impaired glucose metabolism in patients with PA underscores a clinically significant link between aldosterone excess and metabolic dysfunction.These metabolic characteristics may function as supportive factors for primary care physicians in assessing hypertensive patients with elevated cardiovascular risk.

Conclusion: Nearly one-third of patients with primary aldosteronism had metabolic syndrome, suggesting that routine metabolic screening in hypertensive patients may help general practitioners identify those at higher risk and improve cardiovascular management.

ID 1570- Atypical Presentation of Mycoplasma pneumoniae Dilated Myocarditis Leading to Stroke

Ma LI, Taihong LV, Shan ZHOU, Yanli LIU

Department Of General Medicine, Beijing Tiantan Hospital, Capital Medical University, Beijing, Chine

Context: To investigate the knowledge and current management status of Mild Cognitive Impairment (MCI) among general practitioners (GPs) in primary care.

Objectives: A questionnaire survey was conducted among GPs in primary care. The electronic questionnaire was distributed via the Fengtai District Community Health Service Administration Center from January 2024 to May 4, 2025, and completed by the participating GPs voluntarily. Statistical analysis was performed using SPSS 22.0 software. Measurement data were expressed as mean ± standard deviation ($\bar{x}\pm s$), and count data were expressed as composition ratios or rates.

Methods: A total of 185 questionnaires were distributed, with a recovery rate of 100%. The knowledge of GPs regarding MCI diagnostic criteria, risk factors, and screening tools was relatively low. Community health service centers had insufficient experience in MCI management. Regarding training needs, 64.9% of GPs expressed a desire for MCI-related training. The order of training needs was as follows: MCI screening, diagnosis, risk factor identification, treatment plans, prognosis, and comprehensive management.

Results: The knowledge of MCI among GPs is not optimistic. Strengthening training for GPs to improve their MCI-related knowledge will help identify MCI patients earlier and delay disease progression.

Discussion: This survey indicates that primary-care GPs have limited knowledge of MCI diagnostic criteria, risk factors, and screening tools, and community health service centers lack standardized management experience. The high training demand, prioritizing screening and diagnosis, points to practical gaps that may delay case detection. Targeted continuing education, adoption of validated screening instruments, and clear referral and follow-up pathways could strengthen early identification and continuity of care.

Conclusion: GP knowledge and management capacity for MCI are insufficient. Strengthening structured, practice-oriented training—especially in screening and diagnosis—may improve early detection and support timely management, potentially slowing disease progression.

ID 1749- Atypical Presentations of Celiac Disease in Adult Women: A Practice-Based Reflection from Primary Care

Hazel LUCI

Southern Isabela Medical Center, Quirino, Philippines

Context: This case examines a household in the launching stage of the family life cycle, a period when children transition toward independence. Ordinarily, this stage requires parents to redefine roles and cope with the "empty nest" experience. However, the father's diagnosis of multidrug-resistant tuberculosis (MDR-TB) complicates this transition, creating overlapping stressors for both patient and family. The impact of illness is profound, producing distress, isolation, and diminished self-worth in the patient, while the family faces financial burdens and anxiety. Misconceptions about TB were corrected through the Health Belief Model, improving self-efficacy and adherence. Within the family illness trajectory (Stage III), the physician coordinates therapy and education, underscoring the need for holistic, family-centered care.

Methods: The method used is a holistic, family-centered case study approach, combining SCREEM, ecomap, family life cycle analysis, illness trajectory, and the Health Belief Model. This multi-framework method allows physicians to assess medical, psychological, social, cultural, and economic dimensions, ensuring comprehensive care planning and family adaptation.

Originality: Can be seen in how people approach challenges, express themselves, or invent solutions.

Lessons learned and future implications: Illness during the launching stage of the family life cycle magnifies vulnerabilities but also reveals resilience. With coordinated medical care, family support, and community resources, both patient and family can adapt, sustain hope, and navigate the challenges of TB while maintaining functional family roles.

Discussion: Tuberculosis (TB) is an infectious disease caused by Mycobacterium tuberculosis, primarily affecting the lungs. It is both curable and preventable, yet remains a major global health challenge. Transmission occurs through airborne particles released when an infected person coughs, sneezes, or talks. Individuals infected with TB bacteria face a 5–10% lifetime risk of developing active disease. The 6-month BPaLM regimen is currently the preferred option for most MDR/RR-TB patients, offering improved outcomes compared to older, longer treatments

Conclusion: MDR-TB is not solely a biomedical condition but a multifaceted challenge encompassing medical, psychological, social, and economic dimensions. Addressing this disease requires coordinated action among patients, families, healthcare providers, and policymakers. A holistic, family-centered strategy is imperative to mitigate the adverse impacts of MDR-TB, restore health, and safeguard the long-term well-being of affected households.

ID 123- Audit; Sick Day Rule advice in patient's prescribed SGLT2 inhibitors.

Nikki Rose AGCAOILI

Southern Isabela Medical Center, Santiago City, Isabela, Philippines

Context: Tuberculosis remains a major public health challenge in the Philippines, which ranks among the highest TB-burden countries globally. Despite effective treatment, substantial gaps in case detection persist, particularly in rural and underserved communities. In San Manuel, Isabela, TB case detection rates consistently fell below provincial targets, contributing to delayed diagnosis, continued transmission, and preventable morbidity. Structural barriers such as stigma, transportation costs, limited diagnostic access, and low health literacy hinder timely care. This Community Oriented Primary Care project, "It's Time! To Be Tested," was developed to strengthen TB case detection through community engagement and primary care integration.

Methods: A COPC framework guided the project, beginning with community characterization and problem prioritization using local health data, program reports, and stakeholder consultations. Key barriers to TB detection were addressed through multicomponent interventions, including community education campaigns, active case

finding, mobile TB caravans with chest X-ray and sputum collection, and capacity building for barangay health workers. Public–private partnerships and intersectoral collaboration with the local government unit, Department of Health, and community organizations supported implementation. Monitoring focused on screening coverage, diagnostic yield, and TB case detection trends.

Originality: This project demonstrates how a rural primary care unit operationalized COPC principles to improve TB case detection by integrating health education, active case finding, and system-level strengthening. It highlights the central role of family physicians in translating national TB strategies into community-responsive actions.

Lessons learned and future implications: Improved TB detection was facilitated by reducing access barriers through mobile diagnostics, engaging trusted community actors, and embedding TB screening into routine and regulatory health processes. Persistent challenges included stigma, funding limitations, and workforce constraints. Institutionalizing TB initiatives through local ordinances, sustained financing, continuous training, and strengthened referral systems is essential for long-term impact.

Discussion: Active case finding and community-based screening proved more effective than passive approaches in identifying undiagnosed TB cases. Strengthened public–private linkages and routine monitoring enhanced notification, follow-up, and treatment initiation, contributing to improved program performance.

Conclusion: "It's Time! To Be Tested" shows that COPC-driven, community-engaged strategies can strengthen TB case detection in resource-limited settings. Empowering communities and reinforcing primary care systems are critical to sustaining gains and advancing toward a TB-free San Manuel.

ID 1828- Auriculotherapy as an Occupational Health Strategy: Reducing Stress and Pain Among Healthcare Professionals

Liesbeth HUNIK [(1)] , Annemarie UIJEN [(1)], Tim OLDE HARTMAN [(1)], Twan VAN LAARHOVEN [(2)], Henk SCHERS [(1)]

(1) Radboudumc, Department Of Primary And Community Care, Nijmegen, Pays-Bas
(2) Radboud University, Institute For Computing And Information Science, Nijmegen, Pays-Bas

Context: Artificial intelligence (AI) based diagnostic prediction models are able to predict the likelihood of a disease based on routine healthcare data and may support general practitioners (GPs) in the diagnostic process. However, the development of such models into fit-for-practice- tools does generally not involve GPs. It is therefore unclear how GPs asses such an AI based prediction tool.

Objectives: To explore the impact of an AI based diagnostic prediction tool on 1) the diagnostic decision making; and 2) the experiences of GPs and GPs in training with regard to its usefulness and reliability.

Methods: This study has two parts. The first part consists of interviews with a panel of GPs and GPs in training to map the needs and preferred functionalities of the tool. Vignettes have been created based on the results of the interviews and real patient consultation data. These vignettes show consultations of individual patients, either with or without the use of a diagnostic prediction tool. This tool presents a differential diagnosis considering patient variables such as age, sex and reason for encounter. In the second part of the study, we test the clinical vignettes on GPs and GPs in training. The impact of the tool on the diagnostic decision-making process and the usability (from the System Usability Scale) and reliability is explored. Descriptive statistics will be used to describe the results.

Results: Data collection and vignette development are ongoing. Findings of both parts of the study will be available by the time of presentation.

Discussion: Using an AI based diagnostic prediction tool during consultation might result in less diagnostic testing, especially for less experienced doctors. In-depth interviews will be needed to further explore the results of this study. Furthermore, research in a real-time setting is needed.

Conclusion: This study will provide insights into whether an AI-based diagnostic prediction tool can support GPs and GPs in training by influencing diagnostic decision-making and whether it is perceived as usable and trustworthy in clinical practice.

ID 506- Australian GP experience diagnosing and managing opioid dependence in patients' prescribed opioids for chronic pain, 2021 to 2023.

Emmanuela FERNANDOVA

Prakticky Lekar Krtiny, Brno, Tchéquie

Context: A 75-year-old female patient, who had undergone a partial gastrectomy for recurrent bleeding ulcers in May, presented to her general practitioner (GP) in July with a two-week history of back pain. Despite recent major surgery and clinical symptoms (exertional dyspnea, edema, diminished breath sounds), the patient insisted she felt "well" and attributed the pain only to prolonged bed rest, explicitly refusing hospital referral.

Methods: A clinical assessment was performed in the GP's office, including physical examination and laboratory testing (CRP). To overcome the diagnostic uncertainty and the patient's reluctance, the GP performed a Point-of-Care Ultrasound (POCUS) examination of the lungs and abdomen. Subsequent management involved referral to a university hospital for CT imaging, drainage, and antibiotic therapy.

Originality: This case demonstrates a rare and life-threatening delayed post-operative complication: a subphrenic liver abscess that led to a massive tension fluidothorax (pleural empyema). It highlights the unique role of a GP who, despite a patient's subjective feeling of being "fine," used bedside technology to diagnose a condition that required the drainage of 3,800 ml of fluid.

Lessons learned and future implications: 1.Post-operative complications can present with misleading musculoskeletal symptoms (back pain). 2.Geriatric patients often understate their symptoms, requiring high clinical suspicion. 3.POCUS is a crucial "visual stethoscope" in primary care that can objectively confirm a diagnosis and facilitate necessary hospitalization in reluctant patients.

Discussion: The diagnostic pitfall lay in the discrepancy between the patient's refusal of care and her severe physiological state (CRP >270 mg/l). The POCUS finding was the decisive factor for immediate referral. Cultivation confirmed Streptococcus alpha-hemolyticus. This case emphasizes the GP's role in the long-term follow-up of surgical patients and the benefits of integrating ultrasound into routine practice.

Conclusion: General practitioners must remain vigilant when post-operative patients present with "simple" complaints. POCUS significantly increases diagnostic accuracy in the primary care setting, allowing for the timely detection of massive pleural empyema and other internal complications that physical examination alone might miss.

(2) Royal College Of General Practitioners, Warwick, Royaume-Uni
(3) College Of Family Physicians Of Canada, Windsor, Canada

Context: Digital Twins (DTs) in healthcare are digital models of patients, organs, or processes that undergo updates in real-time, allowing simulation and analysis of health trajectories and outcomes. This helps clinicians develop a personalised management plan for patients

and facilitate shared decision-making. DTs are successfully being used in hospital based specialites for personalised treatment of patients. However, their application in primary care remains largely unexplored.

Objectives: To understand the concept of a human digital twin. To identify at least three primary care use cases of digital twins. To discuss practical implementation challenges and opportunities.

Teaching method and workshop: Teaching method: Interactive teaching and small group discussion Workshop schedule: 0–5 min — Welcome and poll Introduction and establishing a baseline of knowledge among the participants. 5–15 min — Discussion of the main concept Definition of digi

Expected outcomes: By the end of the workshop, participants should have a clear understanding of the concept of digital twins, have an idea of the practical uses of DTs in primary care, and have an awareness of the limitations and ethical considerations relating to this tec

Conclusion: Digital twins are an evolving technology. Their use in primary care can have a beneficial impact on health outcomes for patients and may result in a reduction in workload for clinicians. However, there are potential limitations and ethical considerations that need to be addressed before this technology can be widely adopted in primary care.

ID 2054- Balance, Strength, Safety: Reducing Falls in Older Adults

Carlos MARTIN, Ines ARANCIBIA, Josep Maria VILASECA

Fundación Althasia, Manresa, Espagne

Context: We describe the experience of a home care team in which nurses are the main providers of POCUS examinations at patients' homes.

Methods: Our home care team consists of a nurse, a physician and a clerk, providing continuity of care for approximately 120 homebound patients with complex chronic conditions, elderly patients, disabled patients or palliative needs. The team completed six accredited POCUS (Point of Care Ultrasound) training sessions covering the main systems: lung, vascular, abdominal, soft tissue, musculoskeletal and FAST examination. After, completion of training (October 2025), home-based POCUS examinations were systematically incorporated into clinical practice.

Originality: The originality of this topic lies in the fact that, to date, most ultrasound examinations have been performed by medical professionals. This work demonstrates that nursing staff are also adequately trained to perform ultrasound examinations correctly and to draw accurate clinical conclusions from them.

Lessons learned and future implications: Seven, home-based POCUS examinations were performed during the study period, all conducted independently by nurses, within their scope of practice. Indications included vascular assessment (n=2, suspected deep vein thrombosis), lung ultrasound (n=2, suspected heart failure exacerbation), and abdominal ultrasound (n=3, including suspected bladder neoplasm, ascites and hepatic pathology related to jaundice). In all cases, POCUS findings confirmed the initial diagnosis. None of the patients required transfer to hospital or additional outpatient imaging and the acute clinical condition was solved at home.

Discussion: Although the ultrasound equipment used in this study performs well, it poses challenges for home use due to its large size and significant weight. This makes it difficult to handle in a domestic setting. Even that the number of patients examined so far is low, POCUS performed by a nurse is extremely useful to clarify the initial diagnosis and to avoid referrals to the hospital and to the emergency room. Nurses are enough skilled to perform POCUS and to contribute to the diagnosis and treatment of the patient at home.

Conclusion: In conclusion, nurses are skilled to perform point of care ultrasound with high

quality. This experience can be generalized to broader settings. Further studies with a larger number of cases are needed to reinforce these conclusions.

ID 1915- Balancing suspicion and diagnosis in suspected child abuse in a rural primary care setting: A practice-based reflection

Emma HARRISON, Karla MADRID, Joy DRAPER

Self Regional Healthcare Family Medicine Residency Program, Greenwood, Sc, États-Unis

Context: Non-immune fetal hydrops (NIHF) is a rare, life-threatening fetal condition associated with high fetal mortality. Outcomes depend on early recognition, prompt referral, and multidisciplinary management. In rural settings, access to Maternal-Fetal Medicine (MFM) specialists is often limited, making Family Physicians trained in both obstetrics and point-of-care ultrasound (POCUS) critical for early detection and care coordination.

Methods: A 34-year-old G2P1001 at 17 weeks 5 days gestation presented to a rural family medicine clinic for routine prenatal care. POCUS revealed fetal ascites, cranial edema, and abnormal limb development, raising immediate concern for fetal hydrops. Urgent referral to MFM was initiated, and within 48 hours severe NIHF was confirmed. Amniocentesis revealed trisomy 21, and infectious and structural cardiac evaluations were negative. The patient elected expectant management and was co-managed weekly by Family Medicine and MFM with alternating visits to minimize travel while ensuring close fetal and maternal surveillance for mirror syndrome. Fetal demise occurred at 22 weeks 3 days, followed by uncomplicated induction of labor. Strengths of this approach included early diagnosis through POCUS, expedited specialist access, and coordinated longitudinal care. Limitations included lack of fetal therapeutic options.

Originality: This case uniquely highlights the utility of rural, obstetrically trained family physicians using POCUS to diagnose life-threatening NIHF and rapidly mobilize subspecialty care. Few reports emphasize rural-led detection and an effective co-management model between Family Medicine and MFM physicians in severe fetal pathology.

Lessons learned and future implications: Access to obstetrical-trained family medicine physicians proficient in POCUS can significantly shorten time to diagnosis of high-risk fetal conditions in rural populations. Structured co-management between rural generalists and subspecialists at tertiary centers may significantly improve patient safety and maternal-fetal outcomes.

Discussion: Although NIHF associated with aneuploidy carries a poor fetal prognosis with limited therapeutic options, early diagnosis and vigilant maternal monitoring due to the risk of mirror syndrome is crucial for patient safety.

Conclusion: This case underscores the essential role of rural, obstetrically trained family physicians in the early recognition of severe fetal disease and demonstrates how collaborative co-management with MFM specialists can safely deliver high-risk obstetric care across geographic barriers.

Context: We present our experience when diagnosing Chagas disease in a male migrant patient native of Bolivia who attends the GP due to a 3 day-long lower back pain that does not ease when taking analgesics. No record of previous injuries. Expresses mechanical back pain when flexing/extending the torso. The patient migrated to Catalunya (Spain) 23 years ago due to socioeconomic reasons. We observe

the phenotypic traits of the patient: brown skin, almond-shaped eyes, Roman nose, black, straight hair. We ask his place of origin. He is Quechua, from the Cochabamba valley in the Bolivian Andes mountains. Following the guidelines on migrant patients, we proceed to screen for Chagas disease due to it's high morbidity and mortality and taking into account that Bolivia is the country with the highest prevalence in the world, where Chagas it's an endemic disease.

Methods: We request a Trypanosoma Cruzi serology test, it comes out positive. Confirms Chagas disease, the silent neglected disease. From the Primary Health Centre we investigate about cardiovascular and digestive affectation and a screening of any electrocardiographic alterations. The patient is transfered to the Imported Disease Tropical Medicine Hospital Unit for the echocardiographic study given that 25-30% of Chagas patients have cardiac complications. Monitored and treated by both the Hospital and the Primary Health Centre.

Originality: The fenotype is a non-invasive biomarker that can provide important information.

Lessons learned and future implications: This case calls for the importance to look beyond the reasons for a GP appointment and consider the patient's personal story. Understanding the patient's personal context can save lives.

Discussion: The information that the phenotype (non-invasive biomarker) of the migrant population provides is relevant, although not conclusive.

Conclusion: It's necessary to approach the patient with a holistic vision: to listen, understand and observe to provide the appropriate support.

Unitat De Suport A La Recerca Metropolitana Nord, Idiap Jordi Gol, Mataró, Espagne

Context: Some individuals infected with SARS-CoV-2 experience a wide range of mid- to long-term symptoms, a condition known as Long COVID. The long-term mental health consequences of the COVID-19 pandemic are of growing concern, particularly among individuals with Long COVID and cognitive complaints.

Objectives: To explore the presence and distribution of anxiety, depression, and stress in individuals with Long COVID with cognitive complaints in northern Barcelona (Spain).

Methods: This cross-sectional study included 155 diagnosed individuals with Long COVID who were recruited from the Aliança ProHEpiC-19 Cognitiu (APC) project. Sociodemographic characteristics were collected, and mental health outcomes were assessed using the self-administered Depression, Anxiety, and Stress Scale (DASS-21). Descriptive statistics, $\chi 2$ tests, and Poisson regression models were used for data analysis.

Results: High levels of psychological distress were observed in the sample, with a notable prevalence of severe stress and extremely severe anxiety. Symptoms of stress, anxiety, and depression were consistently high across sex categories, work settings, and educational levels. Significant differences were found in anxiety and depression according to age and job role, with individuals aged over 45 years and non-healthcare workers showing higher relative risks ($p < 0.05$).

Discussion: These findings indicate a substantial mental health burden among individuals with Long COVID and cognitive complaints. Elevated levels of anxiety, depression, and stress were observed across multiple groups, suggesting that psychological distress is a core component of Long COVID. Higher levels of distress were particularly evident among adults over 45 years of age and non-healthcare workers.

Conclusion: This study highlights the significant psychological impact of Long COVID, underscoring the need for targeted mental health interventions. The integration of emotional and psychological support into clinical management plans for long COVID is strongly recommended. Further research is needed to better understand its complex mental health consequences and to inform effective, evidence-based care strategies.

ID 1008- Basic fracture management in family medicine

Ruby Joan GUZMAN, Cesar Matthew MADRIA

Dr., Tuguegarao City, Philippines

Context: Patients' expectations and efficient management of waiting time in outpatient departments are crucial for better service delivery. Turnaround time encompassing waiting and consultation periods, serves as a benchmark for workforce efficiency. Time-motion studies systematically observe, measure, and analyze time spent on tasks, improving workflow and productivity.

Objectives: To assess patient satisfaction in relation to waiting time until discharge at the outpatient department of a government tertiary hospital.

Methods: An institution-based, cross-sectional, observational study was conducted at the outpatient department in a tertiary hospital for one month. A combined chart and video surveillance reviews were used to track time motion. A pretested semi-structured questionnaire was used for the satisfaction survey. Sociodemographic data, time spent per service station (triaging, registration, printing of records, consultation, and discharge), and patient satisfaction were collected. Descriptive statistics summarized turnaround times, and one-sample t-tests compared observed times with recommended standards. Patient satisfaction was measured on a 4-point Likert scale, and Spearman's rho correlated waiting times with satisfaction.

Results: Among 339 respondents, most were middle-aged, 40–59 years, female, and unemployed. The longest delays occurred in registration to printing of records (mean = 66 ± 34.68 min) and printing of records to being called for consultation (mean = 72 ± 53.55 min). Observed processing times significantly exceeded recommended standards ($p < 0.001$). Spearman's correlation demonstrated negative associations between waiting time and patient satisfaction across all stations ($\rho = -0.26$ to -0.42, $p < 0.001$), with the strongest effects at triaging and pre-consultation steps. Nursing and physician care were rated highly (very good to very satisfied).

Discussion: Findings demonstrate an inverse relationship between waiting time and patient satisfaction in outpatient settings. This suggests pre-consultation delays are primary determinants of patient satisfaction, even when nursing and physician care were rated positively.

Conclusion: Longer waiting times in triaging and clinics before consultations negatively impacted patient satisfaction. Despite delays, nursing and physician care were highly rated, indicating dissatisfaction from system inefficiencies rather than clinical interactions. Improving workflow efficiency while maintaining high-quality care is crucial for enhancing OPD patient experience and adherence to service standards. Keywords: Outpatient, patient satisfaction, time-motion study

ID 607- Behavioural Science in Action: Finding Solutions to AMS Challenges in Primary Care

Hazel Sweetzie ANTONIO

Manuel A. Roxas District Hospital, Roxas

Context: Caustic chemical ingestion is a significant public health concern. Household bleach (3–6% sodium hypochlorite) is commonly involved in intentional or accidental poisonings. In adults, ingestion is often deliberate and associated with psychosocial stressors, family dysfunction, or mental health

challenges, leading to substantial morbidity. This case presents a 35-year-old female who ingested bleach following a family conflict, illustrating the interplay of biomedical, psychosocial, and family factors in self-poisoning.

Methods: A family case study approach was used, integrating patient-centered assessment, family-focused evaluation, and community-oriented interventions. Data collection included patient interview, physical examination, review of medical history, and psychosocial assessment using PHQ-9, Family APGAR, SCREEM, FICA Spirituality Tool, and genogram mapping. Acute management included supportive care with intravenous fluids, oxygen, hydrocortisone, and vitamin supplementation. Family-centered interventions involved CEA (Catharsis, Education, Action) counseling, coordination with the Rural Health Unit and Municipal Health Office, psychiatric referral, and monitoring of at-risk family members.

Originality: This case emphasizes a holistic approach to intentional chemical ingestion in a rural setting, combining biomedical care with psychosocial, family, and community interventions—an approach not commonly documented in local literature.

Lessons learned and future implications: Early recognition of emotional distress, open family communication, and integration of community resources are critical. Preventive education on poison safety, mental health awareness, and adherence to RA #11036 can reduce recurrence.

Discussion: Intentional bleach ingestion reflects deeper family and psychosocial stressors. Management requires stabilization of the patient, psychosocial evaluation, family counseling, and coordination with community health resources. This case demonstrates that addressing family dynamics, adolescent behaviors, and marital challenges alongside clinical care enhances coping and resilience. Furthermore, community-level health education and preventive strategies are essential in rural settings to minimize the risk of similar events.

Conclusion: A multidisciplinary, holistic approach that integrates patient-centered care, family-focused interventions, and community-oriented strategies is essential in managing intentional chemical ingestion. Beyond acute medical stabilization, attention to family cohesion, mental health support, and preventive education ensures long-term wellbeing and reduces recurrence risk.

ID 492- Behind the White Coat: Gender, Work–Life Balance, and Career Progression Among Family Physicians in Türkiye

Sümeyra Nur DELIKKAYA, Ilksen Yazgülü ŞENOL, Vildan MEVSIM

Dokuz Eylu Unıversity Faculty Of Medicine Department, Izmir, Türkiye

Context: Depression is a common psychiatric disorder characterized by depressive mood, anhedonia (loss of pleasure), decreased energy, and impaired daily functioning. In primary care, patients often present with nonspecific somatic complaints such as fatigue or malaise rather than overt psychological symptoms. The continuity of care and comprehensive approach in family medicine enables early recognition of psychiatric disorders and severe psychopathology, such as psychotic features.

Methods: A 28-year-old woman presented to a family medicine clinic with complaints of fatigue, malaise, and hair loss. She reported no chronic illness, regular medication use, or history of surgery. Initial laboratory tests, including thyroid function tests, were normal. On examination, the patient appeared tired and inattentive. The Patient Health Questionnaire-9 (PHQ-9) was administered, yielding a score of 20, consistent with severe depressive symptoms. She denied active suicidal thoughts, and a psychiatric referral was planned. Three days later, the patient returned and reported canceling her psychiatry appointment, stating, “I believe God sent me to you.” She explained that a psychologist she spoke to by phone opposed psychiatric

evaluation and suggested alternative approaches. During the consultation, she exhibited disorganized thought processes, frequently changed topics, and expressed beliefs that she was being punished by God and that her family was trying to take her property through forced marriage. These delusional beliefs indicated disturbances in thought content. A preliminary diagnosis of psychotic depression was considered, and an urgent psychiatric referral was reinstated.

Originality: This case demonstrates that severe depression with psychotic features can initially present with vague somatic complaints, highlighting the importance of diagnostic responsibility in primary care that goes beyond symptom-focused evaluation.

Lessons learned and future implications: Screening tools such as the PHQ-9 are valuable for patients presenting with nonspecific complaints.

Discussion: Primary care physicians can recognize early signs by paying attention to behavioral changes and unusual thought patterns.

Conclusion: Primary care plays a central role in the early recognition of complex depressive disorders. Careful assessment can reduce delays in the treatment of depression. Keywords (MeSH): Depressive Disorder, Psychotic Depression, Primary Health Care, Patient Health Questionnaire, Somatic Symptoms, Delusions, Referral and Consultation

ID 2045- Between Patient, Planet and System: Rethinking the Bedrock of Family Medicine

Hazel Sweetzie ANTONIO

Manuel A. Roxas District Hospital, Roxas, Philippines

Context: Infertility is a complex, multifactorial condition influenced by endocrine, psychological, familial, and social factors. The coexistence of hyperthyroidism and polycystic ovary syndrome (PCOS) significantly disrupts reproductive function through compounded hormonal dysregulation, anovulation, and metabolic disturbances. Social pressures, cultural expectations, and emotional stress further exacerbate the psychosocial impact of infertility, highlighting the need for holistic care in family medicine practice.

Methods: We present a case of M.T., a 35-year-old woman with PCOS and recurrent hyperthyroidism, married for seven years and childless. Family assessment tools including Family APGAR and SCREEM indicated highly functional family dynamics and adequate resources. The CEA (Catharsis, Education, Action) framework guided family-oriented counseling, addressing emotional distress, misconceptions, and coping strategies. Clinical management included pharmacologic interventions, lifestyle modifications and referral coordination with endocrinology and reproductive specialists. Spiritual assessment using FICA addressed faith-based coping.

Originality: This case highlights the intersection of endocrine pathology, psychosocial stressors, and family dynamics in infertility management, emphasizing a patient-centered, family-focused, and community-oriented approach. Integrating medical, emotional, social, and spiritual dimensions provides a comprehensive model for chronic infertility care in resource-limited settings.

Lessons learned and future implications: Family support, open communication, and holistic counseling significantly enhance coping and adherence to medical treatment. Attention to the emotional burden of infertility, social stigma, and faith-based resilience is essential in guiding patients and families through long-term reproductive challenges. Future strategies should incorporate multidisciplinary collaboration, community awareness, and structured fertility support programs to optimize outcomes.

Discussion: Hyperthyroidism and PCOS synergistically impair ovulation and fertility, requiring careful endocrine management and reproductive planning. Addressing psychological stress, marital strain, and social expectations is equally critical. The integration

of family-focused counseling, lifestyle optimization, and spiritual support underscores the importance of holistic care beyond pharmacologic interventions.

Conclusion: Effective infertility management in patients with coexisting hyperthyroidism and PCOS necessitates a multidimensional approach. Combining endocrine treatment with psychosocial, familial, and spiritual support promotes resilience, strengthens family functioning, and improves the overall well-being of patients navigating chronic infertility.

ID 1930- Beware of the "purple crocodile": workshop on absurd certificates that reduce GPs' medical time in Europe

Aiste ZIAUGAITE, Gintare SIAUDIKYTE

Lsmu Lithuanian University Of Health Sciences, Kaunas, Lituanie

Context: Postpartum fatigue and nonspecific symptoms are common complaints in family medicine and are often normalized as part of recovery. However, rare endocrine disorders such as Sheehan syndrome can present subtly and remain undiagnosed, potentially leading to prolonged morbidity. This case highlights the importance of considering endocrine causes in postpartum women with persistent symptoms.

Methods: A 30-year-old woman presented to her family physician six months after delivery with persistent fatigue and generalized weakness that interfered with daily activities. Her delivery had been complicated by severe postpartum hemorrhage, requiring urgent management. Since childbirth, she reported inability to lactate, secondary amenorrhea and dizziness on standing. She denied symptoms suggestive of postpartum depression. Physical examination revealed low-normal blood pressure and mild bradycardia, with no neurological deficits or other remarkable findings. Based on her obstetric history and persistent multisystem symptoms, hypopituitarism was suspected, and further laboratory evaluation was performed. The results confirmed a diagnosis of Sheehan syndrome. Hormone replacement therapy was initiated, resulting in gradual improvement in fatigue, orthostatic symptoms, and overall functional capacity over subsequent months, allowing her to resume normal daily activities.

Originality: Sheehan syndrome is rare in high-resource settings and often presents acutely. This case is notable for its subtle presentation with nonspecific postpartum symptoms. Literature on mild or insidious cases in primary care is limited. The case demonstrates the value of primary care in early recognition of rare conditions through careful assessment of postpartum women.

Lessons learned and future implications: Persistent postpartum fatigue, failure to lactate, and amenorrhea should prompt evaluation for Sheehan syndrome. Early recognition and management enable improved outcomes. Family physicians should maintain vigilance for rare endocrine disorders and consider structured postpartum assessment protocols.

Discussion: Sheehan syndrome results from ischemic pituitary necrosis following severe postpartum hemorrhage. Symptoms may include fatigue, hypotension, amenorrhea, lactation failure, and cold intolerance. Because these symptoms often overlap with normal postpartum changes, diagnosis can be delayed. Family physicians, through holistic assessment and longitudinal care, are well-positioned to detect early signs and initiate treatment.

Conclusion: Sheehan syndrome can present subtly with nonspecific postpartum symptoms. Awareness in primary care, combined with obstetric history and systematic postpartum assessment, allows timely recognition, appropriate treatment, and improved patient recovery.

Unitat De Suport A La Recerca Metropolitana Nord, Idiap Jordi Gol, Mataró, Espagne

Context: Long COVID is a multisystemic condition that complicates diagnosis due to the nonspecific and heterogeneous nature of its symptoms. The most frequently reported symptoms are fatigue, brain fog, cognitive impairment, insomnia, dizziness, and vertigo. Some symptoms may persist for years, and it is unclear whether they will become permanent. Long COVID substantially impacts affected individuals by impairing their work performance, psychosocial well-being, and overall quality of life.

Objectives: The objective of this study was to evaluate cognition, balance, and retinal fundus findings in individuals with Long COVID compared with healthy controls.

Methods: A cross-sectional study was conducted in the public healthcare network of the Northern Metropolitan Area of Barcelona, including 268 participants (201 with Long COVID and 67 healthy controls). Sociodemographic characteristics, substance use, comorbidities, and COVID-19–related clinical data were collected. Cognition was evaluated using a neuropsychological battery, while balance was assessed through posturography and retinal vascular involvement by retinography.

Results: Most participants were women (80.97%), with a mean age of 48.6 ± 9.5 years. Groups differed significantly in the clinical spectrum of the initial SARS-CoV-2 infection, BMI, and years of education. Long COVID patients showed greater cognitive impairment, with significant differences in the number of affected domains and in most cognitive domain scores ($p \leq 0.001$), except for visuospatial and

visuoconstructive functions. Balance dysfunction was more frequent in the Long COVID group than in controls (45.5% vs. 21.0%; p = 0.001). No significant differences in retinal findings were observed between groups.

Discussion: This study suggests that patients with Long COVID experience significant cognitive impairment. Language, visuospatial, and visuoconstructive abilities appear relatively preserved, whereas executive functions, attention, and memory are the most affected domains. Posturographic findings indicate that balance impairment is not attributable to dysfunction of a single system but rather reflects a generalized involvement of multiple systems contributing to postural control. Long COVID does not appear to cause detectable retinal alterations.

Conclusion: These findings highlight the importance of a comprehensive understanding of the effects of Long COVID and underscore the need for targeted, multidisciplinary interventions.

ID 386- Beyond Borders: Learning Through the XXX General Practice Exchange Programmes

Majdi LAATAR

Istanbul Medipol University, Istanbul, Türkiye

Context: Family physicians have assumed a prominent role in the care of professional and elite athletes. These patients are in search of doctors who can balance high level performance while also protecting their long term health, which requires knowledge beyond injury care. Primary caregivers are able to provide multidisciplinary care through nutrition and metabolizm screening as well as mental health supporting. Developments in sports medicine offers GPs new approaches to safely optimize performance and minimize post retirement complications.

Objectives: To synthesize clinically relevant sports medicine research published between 2023-2025 and highlight practical strategies applicable to routine primary care practice.

Methods: A narrative review sourced from peer-reviewed literature between 2023–2025 was performed, through a search using sports medicine journals. We prioritized systematic reviews, randomized controlled trials and expert consensus statements. We focused on 6 domains essential to comprehensive athlete care: injury prevention, training load management, recovery strategies, nutritional optimization, mental health support, and cardiovascular screening.

Results: Research suggests that a preventive and personalised attitude in the care of athletes is justified. Innovated wearable technology detects overtraining and subclinical exhaustion, before materializing into injury. NMT programs, in low musculoskeletal sports, achieved a decrease in injury rates. Nutritional strategies focusing on optimal protein intake, periodized carbohydrate availability, and targeting of common deficiencies (especially iron, vitamin D) assist in recovery and enhance performance. Literature has identified that sleep and mental health screening are equally important to injury risk and performance. Cardiovascular screening remains essential for identifying asymptomatic pathology in athletes.

Discussion: Family physicians are essential for the management of professional athletes being able to deliver ongoing care, long-term follow-up, also understanding medical and psychosocial backgrounds. Incorporating modern sports medicine knowledge into common practice enables GPs to facilitate performance enhancement while adding assessment of mental health, lifestyle issues and potential future concerns. This methodology validates the necessity of primary care as the cornerstone and a responsible approach to provide care for athletes.

Conclusion: Family doctors offer sports medicine care by maintaining long-term health, also achieving short-term performance goals. Implementing modern approaches into standard practice, are a reliable ally during an athlete's competitive life and provide ongoing support, solidifying its position as the corner stone of sustainable performance and long term wellness.

ID 2094- Beyond Knowledge: Addressing Cognitive Bias in Clinical Supervision

Boris SAMKO, Olivien SASSIAT, Alice PERRAIN

Collège De La Médecine Générale, Tours, France

Context: Individuals with severe mental disorders often present with multiple somatic comorbidities that require close monitoring and an increasing level of physical healthcare as their mental health conditions worsen. Paradoxically, these patients experience insufficient monitoring for chronic physical diseases and reduced access to general medical care. Although several studies have highlighted the barriers these patients face in accessing healthcare, few have focused on their personal experiences in this area.

Objectives: The aim of this study was to explore these patients' experiences of accessing care provided by general practitioners (GP).

Methods: Exploratory qualitative study conducted from November 2023 to June 2024. Involved a purposive, homogenous sample of ten patients with severe psychiatric disorders who were receiving day care at a hospital. Integrative analysis performed, inspired by an interpretative phenomenological approach.

Results: Access to GP care was experienced differently, like a labyrinth with multiple entrances centred around the GP. Their experiences fluctuated in phases, with changes

in direction reflecting the ups and downs of their approach. Several paths were described: the labyrinthine path of carrying one's burden, the rebellious path of turning away from care, the carefree path of passively going along, the secret path of adhering to care, and the privileged path of participating in care.

Discussion: Patients responded to the difficulty of accessing care, exacerbated by their mental disorder, with a reflexivity that gave rise to a projection of their care. Access to care was an opportunity to seek balance and access to oneself. Their experiences highlight the need to consider them for comprehensive care by helping and promoting their empowerment for their ability to act within the framework of shared care decisions.

Conclusion: GP, with their patient-centred approach, should be strongly involved in the care pathway for people with severe psychiatric disorders, in order to break down barriers between different types of care and facilitate collaboration with psychiatrists. Keywords: general practice; mental disorders; access to care, health; continuity of patient care

Context: Conventional workshop structures frequently face challenges in sustaining attendee interest and ensuring information retention. Gamification, which involves incorporating game mechanics into educational environments, offers an effective alternative for transforming training sessions into more dynamic and productive learning experiences. Despite growing enthusiasm for this strategy, numerous instructors lack specific guidance for applying gamification techniques in their training sessions.

Objectives: - Choose fitting game features for different workshop settings - Create appealing reward systems and progress markers - Apply team-based challenge methods that strengthen knowledge acquisition - Measure how well gaming strategies work in their own teaching practice

Teaching method and workshop: This session will follow a three-step process: (1) introducing core gaming concepts that work in learning settings, (2) active exploration of specific techniques like reward systems, progress tracking, and group challenges, and (3) practical work time whe

Expected outcomes: Participants will leave with ready-to-implement gamification tools customized for their specific teaching contexts. Each attendee will develop a concrete action plan containing at least three gaming elements they can immediately integrate into upcoming wo

Conclusion: Gamification represents a practical, evidence-based approach to addressing common engagement challenges in medical education. By systematically applying game mechanics to workshop design, educators can create learning experiences that improve both participation and knowledge retention. This session bridges the gap between gamification theory and clinical teaching practice, providing family medicine educators with actionable strategies that enhance learner engagement without requiring extensive resources or technological infrastructure.

ID 1719- Beyond Self-Reported Health: High Rates of Incidental Glycaemic Abnormalities Identified through Community Screening in a Public Rental Housing Population

Félicité BEGUIN [(1)] , Isabelle ONISKOFF [(1)], Audrey ABRIAL [(1)], Manon LAVIGNE [(1)], Manon RICHARD [(1)], Philippe AZOUVI [(2)], Mathilde CHEVIGNARD [(3)]

(1) Centre Ressources Francilien Du Traumatisme Crânien, Montreuil, France
(2) Ueros Ugecam, Garches, France
(3) Hôpitaux Paris Est Val-De-Marne, Saint Maurice, France

Context: Mild traumatic brain injury (mTBI) represents a public health challenge in terms of number of patients, of which 15–20% suffer persistent long-term symptoms, affecting resumption of daily activities. Authorized under Article 51 of the 2018 Social Security Financing Act, the pilot program “Mild traumatic brain injury: overlooked rehabilitation care pathways” began in March 2023.

Objectives: Very early patient identification from records of emergency department visit for mTBI, and organisation of appropriate follow-up and management, in order to promote rapid recovery and optimal return to family, social, and professional/school activities.

Methods: Four units (three adult, one paediatric) have been deployed in XXX region, each comprising a coordinating nurse, an emergency department, and a Physical and Rehabilitation Medicine department. A network of private practitioners strengthens the links between hospital and community care. Coordinators identify patients through emergency department records or referral by a general practitioner. They contact patients 15 days post-mTBI (D15) for a telephone assessment and provide advice, reassurance, and psychoeducation regarding symptom management and activity regulation. Patients symptomatic at D15 are contacted again at D30. If difficulties persist, they are referred to a multidisciplinary clinic, which leads, if needed, to an 11-hour psychoeducation program delivered by mTBI expert healthcare professionals.

Results: Between March 2023 and October 2025, 4,429 patients were included; 3,461 (78%) were contacted at D15 and 737 (17%) at D30. A total of 168 patients were referred for multidisciplinary clinic, of whom 136 (3%) entered the psychoeducation program.

Discussion: This pilot program confirmed the high incidence of mTBI and the need for early evaluation and reassurance. It enables rapid, specific, and graded intervention. The number of psychoeducation programs delivered, far lower than expected based on data from the literature (485; 8%), suggests that very early support and reassurance may reduce persistence and impact of post-concussion symptoms.

Conclusion: Results suggest that this intervention reduces anxiety, symptom persistence, and medical wandering. General practitioners can refer patients directly to this program, making them key stakeholders in this care pathway. An program evaluation in 2026 will determine if and how it could be implemented nationwide.

ID 2148- Beyond the acute abdomen: A primary care case of ovarian torsion revealing familial cystic kidney disease

Katrene Cay ACERA

Southern Isabela Medical Center, Santiago City, Isabela, Philippines

Context: Autism Spectrum Disorder (ASD) is a lifelong neurodevelopmental condition that is often under-recognized and misdiagnosed in primary care, particularly in low- and middle-income countries. Adult presentations of ASD remain uncommon in family medicine literature, despite their significant clinical, psychosocial, and caregiver implications. The challenges are magnified in resource-limited rural settings where access to specialist services is constrained. This case highlights the role of family physicians in identifying ASD in adulthood and addressing the complex needs of both patient and caregiver through a holistic, community-oriented approach.

Methods: This paper presents a descriptive family case of adult twins diagnosed with ASD managed in a rural primary care setting. Clinical evaluation included comprehensive history-taking, physical examination, and functional assessment using the Mini Mental Status Examination (MMSE) and Adaptive Behavior Assessment System (ABAS). Family dynamics, resources, and caregiver burden were assessed using Family APGAR, SCREEM-RES, family lifeline, ecomap, and Modified Caregiver Strain Index (MCSI). Management followed the Patient-Centered, Family-Focused and Community-Oriented Care, emphasizing interdisciplinary collaboration and linkage with local government and community resources.

Originality: Case is distinctive in presenting late-diagnosed adult ASD complicated by chronic medical comorbidities and severe caregiver strain within a single-parent household. It demonstrates the pivotal role of family physicians in correcting misdiagnosis, coordinating long-term care, and addressing caregiver well-being in the absence of readily accessible specialist services.

Lessons learned and future implications: Routine developmental surveillance and functional assessment should be integrated into primary care across the life course. Family physicians must proactively assess caregiver strain and mobilize community-based resources. Strengthening primary care capacity for ASD recognition and caregiver support can reduce health inequities in underserved communities.

Discussion: Delayed diagnosis of ASD in adulthood contributes to fragmented care, inappropriate labeling, and psychosocial distress for families. This case illustrates that structured family assessment, continuity of care, and community engagement can improve disease understanding, treatment adherence, and caregiver coping despite persistent functional limitations.

Conclusion: Family medicine is uniquely positioned to provide comprehensive, continuous, and compassionate care for individuals with ASD and their families. Integrating clinical, family, and community perspectives enables primary care to address complex neurodevelopmental conditions and caregiver burden, reinforcing the central role of family physicians in holistic health care delivery.

Context: Arterial hypertension (AH) and atrial fibrillation (AF) are highly prevalent cardiovascular disorders that frequently coexist and represent major public health challenges. AH substantially increases the risk of AF and plays a pivotal role in atrial remodeling; however, the underlying pathophysiological mechanisms remain only partially understood.

Objectives: To evaluate the association between arterial stiffness (AS) and selected inflammatory and fibrotic biomarkers involved in AF development in patients with AH.

Methods: The study enrolled 89 patients with AH and non-valvular paroxysmal or persistent AF (mean age 62.6 ± 7.4 years) after successful cardioversion and 74 hypertensive patients without AF as controls, they underwent echocardiography, inflammatory and fibrotic biomarkers including hsCRP, IL-6, and transforming growth factor-β1 (TGF-β1), were measured, AS was assessed using the cardio-ankle vascular index (CAVI). Statistical analysis was performed using SPSS 13.0 with logistic regression and results expressed as odds ratios (ORs).

Results: Patients with AH and AF showed significantly increased odds of atrial and ventricular electrical and structural remodeling, diastolic dysfunction, higher AS, and elevated inflammatory biomarkers. In

paroxysmal AF, significant predictors included diastolic blood pressure (DBP; OR 1.09, p = 0.017), P-wave maximum duration (Pmax; OR 3.74, p = 0.001), P-wave dispersion (Pdis; OR 3.97, p = 0.001), CAVI (OR 1.83, p = 0.02), left atrial volume (LAV; OR 1.76, p = 0.013), hsCRP(OR 5.57, p = 0.017).In persistent AF, predictors included DBP (OR 1.29, p = 0.001), Pmax (OR 4.73, p = 0.001), Pdis (OR 4.66, p = 0.001), CAVI (OR 2.22, p = 0.01), LAV (OR 3.69, p = 0.001), interventricular septal thickness (OR 1.79, p = 0.042), IVRT (OR 3.94, p = 0.016), and elevated hsCRP (OR 6.37, p = 0.001), IL-6 (OR 5.78, p < 0.001), and TGF-β1 (OR 3.84, p < 0.05).

Discussion: Increased AS, inflammation, fibrotic activity appear to be key mechanisms linking AH to AF. Elevated hsCRP, IL-6, and TGF-β1 likely reflect progressive atrial remodeling, highlighting AS as an integrative marker for risk stratification and prevention.

Conclusion: Multivariate analysis revealed that atrial and ventricular dysfunction, inflammation, and arterial stiffness independently increase AF risk in hypertensive patients, emphasizing the need for early detection and targeted preventive strategies.

ID 1783- Beyond the basics: exploring practical anthropological qualitative methods for everyday general practice.

Marco DE FABRITIIS

General Practitioner, Ausl Romagna, Cesena, Italie

Context: Chronic Kidney Disease (CKD) represents one of the most significant global health challenges, with high prevalence in the adult population and with strong clinical, economic, and social impact. CKD is characterized by a progressive decline in renal function to end-stage kidney disease requiring renal replacement therapy, and is associated with reduced quality of life, increased cardiovascular risk, and a rise in healthcare expenditure.

Objectives: This study examines the integrated management of CKD between general practitioners and hospital nephrologists in the XXX, with particular reference to the Regional Diagnostic, Therapeutic and Care Pathway introduced in 2019 and the most recent K-DOQI guidelines published in 2024.

Methods: The recent definition and classification of CKD, including the emerging role of cystatin C clearance as a diagnostic and prognostic tool, highlight the importance for continuous updating and strengthening of integration between general pratictioners and hospital specialists.

Results: The study underlines the impact of innovative therapies, such as SGLT2 inhibitors, the new medication used to treat high blood potassium, biologic drugs for primary and secondary glomerulopathies, as well as new treatments for anemia and hyperparathyroidism. The analysis of regional epidemiological data demonstrates a significant potential for the implementation of these therapies, with clear benefits in terms of reducing disease progression and improving quality of life.

Discussion: I propose operational strategies to enhance collaboration between hospital and primary care, improve access to innovative treatments, adopt integrated care models based on the latest scientific evidence to improve the disease progression and patients' quality of life, and optimize the use of healthcare resources at the regional level and develop integrated digital monitoring systems, with the aim of optimizing CKD management.

Conclusion: The treatment of CKD requires a multidisciplinary and flexible approach. Collaboration between general practitioners and nephrologists, supported by digital tools and continuous medical education, represents the key to the success of an effective and sustainable care network.

ID 256- Beyond the label: the hidden world of endocrine disruptors in everyday products and their effects on personal and public health

Elena Adorata COMAN

University Of Medicine Grigore T Popa, Iasi, Roumanie

Context: This project had risen as a necessity of adapted medical education to specific target population and develops evidence based medical issues concerning medical providers and the population—personalized medicine.

Objectives: The main objective of the project is to promote equitable access to primary health care by establishing a cross-border partnership between local authorities, medical institutions, and universities in Iași and Ungheni.

Methods: Key actions include raising awareness and knowledge among medical professionals and the public through common educational materials, improving the quality of care through joint training on clinical procedures and preventive screenings (e.g. maternal and child health, cancer, cardiovascular and chronic diseases), and analyzing costs and social consequences. Research sessions, analysis of the existing situation, and substantiation of materials on the proposed topic: Mother and child (prophylaxis); Cancer screening (with emphasis on "silent" cancers: breast cancer, colon cancer, cervical cancer); Cardiovascular screening, metabolic syndrome, chronic respiratory diseases; Costs and consequences in the primary health care system (health economics) and the social impact of diseases. Common guidelines on the topic: Mother and child (prophylaxis); Cancer screening (with emphasis on "silent" cancers: breast cancer, colon cancer, cervical cancer); Cardiovascular screening, metabolic syndrome, chronic respiratory diseases.

Results: An impact event focused on primary medicine and the topic of prevention was organized in Iași. A campaign was launched to disseminate informative materials, such as brochures for patients and guides for family doctors, to promote prevention and prophylaxis behavior. Scientific research and surveys on prevention and prophylaxis behavior were conducted among residents of the Iași and Ungheni districts, as well as family doctors in these areas. The research aims to support public health policy regarding "primary medicine focused on prevention."

Discussion: Cross - border communities have common and different points of interest and targets of prevention. The key of our survey is to adapt the educational programs to specific regional issues and social hazard as tools in primary care prevention.

Conclusion: Structured and collaborative education can improve healthcare in primary medicine.

ID 1030- Biopsychosocial Impacts of Humanized Care in Chronic Disease Management in Primary Health Care: A Literature Review

Sümeyra Nur DELIKKAYA, Zeynep PEKEL, Vildan MEVSIM

Dokuz Eylu Unıversity Faculty Of Medicine Department, Izmir, Türkiye

Context: Older adults are at increased risk of adverse drug reactions due to multimorbidity, polypharmacy, and age-related changes in pharmacokinetics and pharmacodynamics. Medications with a narrow therapeutic index, such as digoxin, pose a particular challenge in primary care. Reduced renal clearance, dehydration, incorrect dosing, and drug–drug interactions may precipitate digoxin toxicity, which often presents with nonspecific or subtle symptoms. Early recognition in primary care is critical to prevent severe cardiac complications and mortality.

Methods: A 75-year-old woman presented to a family medicine clinic with complaints of dysuria and dark-colored urine persisting for approximately one month. She had difficulty expressing herself and was unable to provide a detailed medical history. Review of electronic medical records revealed a history of heart failure, atrial fibrillation, mechanical heart valve replacement, and type 2 diabetes mellitus. Medication review identified current use of warfarin, digoxin, metoprolol, and metformin. On examination, the patient appeared drowsy and poorly oriented but cooperative. Vital signs revealed severe bradycardia (pulse: 35 bpm) and unmeasurable blood pressure. Emergency medical services

were activated and the patient was transferred urgently with a preliminary diagnosis of digoxin toxicity.

Originality: This case illustrates how nonspecific complaints may mask life-threatening drug toxicity in older adults and highlights the pivotal role of primary care in early recognition.

Lessons learned and future implications: Careful medication reconciliation, attention to vital signs, and involvement of family members are essential safety strategies in elderly patients with polypharmacy.

Discussion: Digoxin toxicity commonly manifests with bradyarrhythmias and hemodynamic instability, particularly when combined with AV node–blocking agents. Dehydration and intercurrent illness may further elevate serum digoxin levels.

Conclusion: Elderly patients using digoxin require vigilant monitoring in primary care. Early suspicion, prompt referral, and emergency intervention are crucial to prevent fatal outcomes. Keywords (MeSH): Digoxin, Polypharmacy, Aged, Primary Health Care, Drug-Related Side Effects and Adverse Reactions, Bradycardia, Heart Failure, Atrial Fibrillation

ID 285- Blended auriculotherapy course for primary health care professionals in Brazil

Hazel Sweetzie ANTONIO

Manuel A.roxas District Hospital, Roxas, Philippines

Context: Hurler Syndrome is a rare lysosomal storage disorder with progressive multisystem involvement. Respiratory complications, particularly recurrent pneumonia, are a major cause of morbidity in affected children. These complications are often magnified in low socioeconomic settings where access to healthcare resources, preventive services, and continuity of care are limited. This family case highlights the interaction of biomedical illness, family dynamics, and social determinants of health in the care of a chronically ill child.

Methods: This case involves JN, a 3-year-old Filipino female with recurrent pneumonia and probable Hurler Syndrome from a low socioeconomic nuclear family with adolescents and young children. A comprehensive family medicine approach was applied, integrating biomedical and developmental assessment with family-focused tools including Family APGAR, SCREEM, FICA Spirituality Tool, Health Belief Model, genogram, family lifeline, and ecomap. Counseling was conducted using the Catharsis–Education–Action (CEA) framework to address caregiver emotional distress, knowledge gaps, and coping strategies. Management combined pharmacologic treatment of pneumonia with non-pharmacologic interventions such as nutritional support, environmental modification, psychosocial counseling, health education, and coordination with government and community resources.

Originality: This case uniquely integrates clinical management of recurrent pediatric pneumonia secondary to probable Hurler Syndrome with in-depth family systems and psychosocial assessment. It underscores the pivotal role of the family physician in coordinating care, mobilizing resources, and addressing caregiver mental health amid moderately inadequate family resources and major therapeutic efforts.

Lessons learned and future implications: Chronic pediatric conditions require holistic, family-centered care beyond disease-focused treatment. Early family assessment, caregiver mental health support, strong primary care involvement, and community resource mobilization are essential to improve resilience and outcomes in resource-limited settings.

Discussion: JN's recurrent pneumonia is explained by Hurler Syndrome pathophysiology, including airway obstruction, impaired mucociliary clearance, cardiopulmonary compromise, immunologic vulnerability, and undernutrition. These risks are compounded by poor housing ventilation, shared sanitation, financial constraints, limited

parental education, and social stigma. Family assessment revealed a moderately dysfunctional family with caregiver strain, mild maternal depression, and limited social and spiritual support. Targeted counseling, education, and resource linkage improved family engagement in care.

Conclusion: Integrating biomedical management with family assessment and psychosocial support enables more sustainable and compassionate long-term care for children with Hurler Syndrome and recurrent pneumonia.

ID 2247- Blind and Ultrasound-Guided Injection Therapy in Contemporary General Practice

Bo Kyung SHINE, Seong-Ho HAN

Department Of Family Medicine, College Of Medicine, Dong-A University, Busan, Corée (République de)

Context: Lithospermum erythrorhizon (gromwell) root contains shikonin derivatives with anti-inflammatory and antioxidant properties, and preclinical studies have suggested protective effects on muscle tissue. However, clinical evidence in humans remains limited. Given that age-related loss of muscle strength contributes significantly to functional decline in older adults, effective and safe nutritional interventions are needed.

Objectives: This study aimed to evaluate the effects of gromwell root extract supplementation on muscle strength and physical function in adults aged 50 years or older with low skeletal muscle mass.

Methods: In this 12-week, randomized, double-blind, placebo-controlled trial, 87 participants were assigned to receive either gromwell root extract (1000 mg/day) or placebo, in combination with supervised resistance exercise. The primary outcomes were peak torque of knee extension and flexion at 60°/s measured using isokinetic dynamometry. Secondary outcomes included lower-limb muscle power, body composition assessed by bioelectrical impedance analysis, handgrip strength, the Short Physical Performance Battery (SPPB), and the EuroQol-5 Dimension (EQ-5D). Safety was evaluated through adverse event monitoring and routine laboratory tests.

Results: Compared with the placebo group, participants receiving gromwell root extract showed significant improvements in right knee extension peak torque (+4.32 vs −0.90 Nm; p = 0.040) and right knee flexion peak torque (+2.92 vs −0.70 Nm; p = 0.041). Muscle power increased significantly in left knee extension (+3.66 W; p = 0.039), right knee extension (+4.63 W; p = 0.046), and right knee flexion (+2.78 W; p = 0.046). No significant between-group differences were observed in muscle mass, handgrip strength, SPPB scores, or EQ-5D scores. The supplement was well tolerated, with no reported adverse events.

Discussion: These findings indicate that gromwell root extract may enhance muscle function (strength and power) rather than muscle quantity, suggesting a possible neuromuscular or performance-related benefit when combined with resistance training. The lack of changes in muscle mass and global functional indices (SPPB, EQ-5D) may reflect the relatively short intervention duration and/or limited sensitivity of these outcomes in this population.

Conclusion: Gromwell root extract improved lower-limb muscle strength and power when combined with resistance exercise and was well tolerated, supporting its potential as a safe nutritional adjunct for older adults with low muscle mass.

ID 784- BMI gain following smoking cessation is associated with reduced risk of Alzheimer's dementia

Sümeyra Nur DELIKKAYA, Ayşe Sena GÜLSOY, Vildan MEVSIM

Dokuz Eylu Unıversity Faculty Of Medicine Department, İzmir, Türkiye

Context: Iron deficiency anemia is one of the most common nutritional deficiencies. Chronic

blood loss due to heavy menstrual bleeding is among the leading causes. When diagnosis and treatment are delayed, severe anemia may develop, resulting in functional impairment and the need for urgent interventions such as blood transfusion. In primary care, especially mothers often present for their children's health needs while neglecting their own symptoms. This case highlights the importance of careful observation and opportunistic assessment in family medicine for identifying severe, potentially life-threatening anemia.

Methods: 37-year-old woman with no known chronic disease and no regular medication use frequently attended a family medicine clinic for her children's illnesses and vaccinations. During one of these visits, the physician observed that the patient appeared markedly fatigued, pale, and had slowed speech, prompting an assessment of her own health. She reported fatigue persisting for approximately one year and increasing difficulty climbing stairs over the previous month. Review of her electronic medical records revealed iron deficiency identified two years earlier, but non-adherence to the recommended iron therapy. A detailed menstrual history disclosed irregular and prolonged menstrual bleeding with excessive blood loss, requiring the use of baby diapers during menstruation. Laboratory evaluation showed a hemoglobin level of 5 g/dL, and the patient was urgently referred to the emergency department via emergency medical services. At follow-up two days later, hospital records indicated that she had received red blood cell transfusion, undergone gynecological evaluation, had a hormonal intrauterine device inserted, and received intravenous iron therapy.

Originality: This case emphasizes the diagnostic importance of opportunistic assessment in primary care and demonstrates how severe anemia may remain unrecognized when individuals prioritize caregiving responsibilities over their own health.

Lessons learned and future implications: Clinicians should pay attention to nonverbal cues such as pallor and fatigue, especially during visits made for family members.

Discussion: Although heavy menstrual bleeding is a well-known cause of iron deficiency anemia, it is often normalized or overlooked by patients.

Conclusion: Untreated iron deficiency may progress to severe anemia requiring emergency intervention. Keywords (MeSH): Iron-Deficiency Anemia, Menorrhagia, Women, Primary Health Care, Blood Transfusion, Mothers

ID 1013- Body Mass Index and Pancreatic Cancer Risk in Individuals with Impaired Fasting Glucose and Diabetes: A Nationwide Cohort Study

Chen ELIMELECH, Lior ZADA, Yuval SHACHAR, Hanny YESHUA

Department Of Family Medicine, Tel-Aviv District, Clalit Health Services, Israel, Tel Aviv, Israël

Context: Family physicians increasingly encounter large language models (LLMs) and other AI tools embedded in clinical, private, and patient-facing systems. These tools can support guideline-concordant, evidence-based communication and continuity of care for the experienced and trained physicians. They may also widen inequities and create confusion with misinformed usage or if outputs are not adapted for language, culture, literacy, disability, or digital access. This workshop presents a replicable, vendor and tool-neutral framework for using AI in clinical workflows that strengthen relational and equitable care in time-pressured practice.

Objectives: Participants in this workshop will be able to: Map a high-impact clinical scenario into an AI-supported consultation workflow. Design prompts and scripts that promote clinical ownership, transparency, and shared decision making. Apply a SAFE-AI framework (Scope, Accountability, Fairness, Explainability) to identify risk, bias, and communication gaps. Adapt AI-generated content for multilingual and multicultural populations. Use safe prompt-design ("prompt engineering") templates transferable across different AI tools/modalities.

Teaching method and workshop: Short interactive plenary plus a live demonstration of an AI-supported consultation, followed by a guided small-group design sprint, using participants cases (e.g., multimorbidity, mental health, chronic disease management). Facilitators provide a structu

Expected outcomes: Clinical AI-assisted workflow tailored to their needs SAFE-AI checklist and draft practice protocol Take-home prompt and workflow templates adaptable across clinical settings

Conclusion: Generative AI is increasingly shaping how patients receive information and how clinicians manage cognitive and administrative load. This presentes a unique opportunity for family physicians to harness language models to deliver multicultural, multilingual, and equitable primary care while keeping, safe AI methods and clinical expertise central. By intentionally designing AI-augmented workflows and developing transferable skills in prompt design, participants can enhance relationship-based, evidence-informed care, improving patient understanding, engagement, and shared decision-making.

ID 1386- Bonds that only rural medicine allows: a reflection on continuity, connection and loss in a small village

Man Li CHAN

Hospital Authority, Hong Kong, Hong-Kong

Context: The waiting time for public orthopaedic assessment and management is always long. Prolong waiting time may impose risks to patients, induce patient anxiety and affect social and family life. Family Medicine (FM) Orthopaedic Triage Clinic [FMTC]was set up to meet the above needs.

Methods: The FMTC was set up in 2022. It is a new initiative with the collaboration between Department of FM&PHC and Department of Orthopaedic in view to solve the long waiting time and provide timely assessment and management for patients. Referral letters mentioned back pain, neck pain, knee pain, heel pain, trigger finger, elbow or shoulder pain were either screened by Orthopaedic specialist or direct referral from public general out-patient clinic[GOPC] channeled to FMTC based on Service Framework and with patient agreement. Instead of the routine Orthopaedic appointment, these patients will be given an appointment (within 1-4 weeks) at the FMTC. They will be seen by family doctors with the support from Orthopaedic specialist via the regular inter-departmental meeting focus on case management and knowledge transfer. Outcome review from 4/2022-9/2024 done.

Originality: 1/ To provide timely assessment and management for patient with orthopaedic problems. 2/ To reduce the workload and relieve orthopaedic specialist clinic waiting time 3/ To provide a training platform for Family Medicine doctor in managing common orthopaedic conditions.

Lessons learned and future implications: Around 4/5 patients [77.7%] were able to return back to community follow up after appropriate assessment, investigation and management and only around 1/5 patients [22.3%] needed further orthopaedic specialist clinic management. It also provides timely assessment and management for the patient with 77% patient attended limit to or less than 3 visits.

Discussion: The FMTC is a successful collaborative service. It helps to relieve the workload of Orthopaedic specialist clinic. It provides an opportunity for skill transfer and enhanced the knowledge and practice among FM doctors under the support of Orthopaedic specialist.

Conclusion: The program provides a triple win solution for patients, family doctors, Orthopaedic specialist & hospital administrator.

ID 1620- Brain Dynamic Audio Stimulation to Improve Sleep and Well-being among Healthcare Workers

Ilit FURMAN JACOBY

Family Medicine Residency Program, Maccabi Healthcare Services, Israel, Tel Aviv, Israël

Context: Cervical cancer is largely preventable through organized screening programs; however, adherence to screening recommendations remains suboptimal. Despite Israel having one of the lowest incidence and mortality rates among OECD countries, only about half of eligible women adhere to recommended cervical cancer screening guidelines. Previous studies have identified demographic and clinical factors associated with reduced screening uptake. Emerging evidence suggests that mental health conditions may influence preventive healthcare engagement, yet findings regarding the association between depression, anxiety, and cervical cancer screening remain inconsistent. To date, no population-based studies in Israel have examined this association.

Objectives: To evaluate the association between depression and anxiety and adherence to cervical cancer screening

Methods: This retrospective cohort study will use data from the Maccabi Healthcare Services Database between January 2018-December 2024. The study population is expected to include approximately 300,000–350,000 women eligible for routine cervical cancer screening during the study period. Participants will be classified into two groups: women with documented pharmacological treatment for depression and/or anxiety for at least three consecutive months, and a control group without psychiatric diagnoses or related medication use. Secondary analyses will stratify women according to formal diagnoses of depression or generalized anxiety disorder, and mental illness severity will be assessed using proxy measures including antipsychotic medication use and psychiatric healthcare utilization. Women with prior abnormal cervical pathology, immunodeficiency, hysterectomy, or initiation of psychiatric diagnosis or treatment after January 1, 2018 will be excluded. The primary outcome is adherence to cervical cancer screening according to national guidelines. Secondary outcomes include screening frequency and healthcare utilization patterns. Analyses will adjust for relevant demographic and clinical covariates.

Results: This is a study in progress, and data analysis is ongoing. The study aims to explore associations between depression, anxiety, and adherence to routine cervical cancer screening

Discussion: The anticipated findings may enhance understanding of how common mental health conditions influence preventive health behaviors and help identify women at increased risk for non-adherence within primary care settings

Conclusion: This study in progress aims to inform family medicine practice by clarifying the relationship between depression, anxiety, and cervical cancer screening adherence, supporting more integrated and patient-centered preventive care strategies

ID 1326- Breaking barriers, gaining rights, achieving dreams: doctors' accessibility inside and outside of the working place

Kai Feng YAM

Jurong Community Hospital, Singapore, Singapour

Context: Communication between inpatient teams and patients' nominated next-of-kin (NOK)/proxies in community hospital wards often relies on synchronous phone calls. This workflow is vulnerable to schedule mismatch, repeated call attempts, fragmented documentation, and misaligned expectations—factors that can reduce patient/caregiver experience and increase staff workload.

Objectives: To illustrate DISCUSS (DynamIc Secure Credentials-verified commUnicationS Software) as a solution to current communication issues and its evaluation protocol. In addition, to report baseline perceptions of current phone-based

communication and acceptability to messaging as an alternative to selective medical updates.

Methods: DISCUSS is a national identity software-authenticated, Electronic Health Records(EHR)-integrated secure messaging channel with one-admission–one-thread architecture, role-based routing to ward pools, structured templates, read-status indicators, and auto-documentation. A convergent mixed-methods evaluation is planned: a 4-week proof-of-concept (POC) in one ward followed by a 4–8-week proof-of-value (POV) in matched intervention/control wards. Quantitative outcomes will be derived from EHR or DISCUSS logs (adoption rate, missed communication, estimated time saved per update, calls avoided, early discharge rates and matched average length of stay. Qualitative interviews will explore usability, workflow fit, perceived safety, and trust. Baseline perceptions were assessed using a pre-implementation survey.

Results: A baseline survey was conducted among 58 respondents (44 proxies, 14 patients): Satisfaction with the ease of communication and frequency of updates was modest (40% and 29% reporting satisfied/very satisfied, respectively). An update-cadence mismatch was prominent: 69% reported currently receiving updates ≤ once weekly, whereas 90% preferred ≥ twice weekly. Office-hours phone update timing was variably compatible with caregiver schedules (33% convenient vs 31% inconvenient). Acceptability of an asynchronous secure-messaging alternative was high: 79% rated it useful, 81% rated it more convenient than phone calls, and 81% were willing to download/login a communication application; proxies showed lower baseline satisfaction than patients but similarly high acceptability.

Discussion: Baseline findings suggest that current phone-based processes do not meet desired update cadence for many patients and proxies, while readiness for secure asynchronous messaging is high.

Conclusion: The DISCUSS protocol provides a pragmatic blueprint for evaluating feasibility, workflow impact, and communication reliability in community hospital settings relevant to family medicine and transitional care. POC findings are expected to be available by June 2026.

(2) Department Of Family Medicine, Chang Gung Memorial Hospital, Linkou, No. 5, Fuxing St., Guishan Dist., Taoyuan City, 333, Taiwan ; school Of Medicine, College Of Medicine, Chang-Gung University, No. 259, Wenhua 1st Road, Guishan District, Taoyuan City, 333,taiwan, Taoyuan, Taïwan

Context: Physical fitness is an important determinant of work ability and is closely associated with work quality, productivity, and overall job satisfaction. In hospital settings, where employees are exposed to sustained physical and psychological demands, impaired physical fitness compromise occupational performance and long-term health. However, the relative contributions of physical, mental, and subjective health factors to physical fitness risk among hospital employees remain unclear.

Objectives: This study aimed to examine independent factors associated with a high risk of physical fitness impairment among hospital employees, with a particular focus on whether these associations differ according to work tenure.

Methods: This cross-sectional study stratified participants by work tenure into those with less than 10 years and those with ≥10 years of employment. Binary logistic regression analyses were performed to identify independent predictors of high risk of physical fitness impairment, adjusting for potential confounders including age, sex, BMI, Waist-to-Hip Ratio (WHR), Skeletal muscle mass, and health-related quality of life domains derived from the SF-36 questionnaire (Physical

Component Summary [PCS], Mental Component Summary [MCS], and General Health [GH]). Tenure-stratified models were further conducted.

Results: A total of 365 hospital employees were enrolled. In tenure-stratified analyses, subjective GH was independently associated with a high risk of physical fitness impairment among employees with ≥10 years of tenure (OR 0.27, 95% CI 0.12–0.62; p = 0.002), whereas PCS and MCS were not significantly associated with physical fitness risk. In this group, higher BMI and WHR were positively associated with physical fitness impairment, while greater skeletal muscle mass and female sex were inversely associated with physical fitness risk. In contrast, no significant independent predictors were identified among employees with less than 10 years of tenure.

Discussion: Among long-tenured hospital employees, subjective general health emerged as a key predictor of physical fitness impairment, outperforming conventional physical and mental health scores. These findings suggest that subjective health perception may capture cumulative occupational and metabolic burdens that are not reflected by traditional health metrics.

Conclusion: Our results indicate that tenure-specific strategies incorporating subjective health assessment may enhance the effectiveness of workplace physical fitness and health promotion programs. Keyword: Physical fitness, health status, occupational health, employment, personnel, hospital

ID 458- Bridging Policy and Reality: Narrative Storytelling as a Cultural Driver of Gender Equity in STEMM

Muataz KHALID

Primary Health Care Corporation (phcc), Doha, Qatar

Context: Sudden cardiac death (SCD) is a catastrophic event that can occur in apparently healthy athletes, often during training or competition. Despite advances in diagnostics, SCD remains a major public health concern, underscoring the critical role of primary care in prevention, risk stratification, and early detection. Primary care clinicians are frequently responsible for pre-participation evaluations, yet face challenges in balancing effective screening with resource limitations and ethical considerations.

Methods: A 19-year-old competitive runner attended a routine pre-participation check-up in primary care. The consultation raised questions about the adequacy of standard screening protocols, which typically rely on history and physical examination alone. Should electrocardiography (ECG) be added? What are the implications of false positives, cost, and psychological impact? This reflection integrates clinical experience with current evidence and international guidelines, comparing approaches that include ECG versus those that do not. Key risk factors considered were inherited cardiomyopathies, arrhythmias, and family history of premature cardiac events. Practical barriers such as access to investigations, cost-effectiveness, and downstream consequences were critically examined.

Originality: This case-based reflection highlights the complexity of screening athletes for SCD in primary care, where decisions must balance preventive benefit with feasibility and equity. It emphasizes ethical and psychological dimensions often overlooked in discussions focused solely on diagnostic accuracy.

Lessons learned and future implications: Primary care clinicians can adopt a tiered approach: comprehensive history and physical examination for all athletes, with ECG reserved for those with red flags such as family history or abnormal findings. Shared decision-making and psychological support are essential. Digital tools and telemedicine can enhance feasibility and reduce unnecessary referrals.

Discussion: Primary care plays a pivotal role in preventing SCD among athletes, yet screening programmes face limitations in predictive value and implementation. Collaborative guidelines, clinician education, and integration of emerging technologies may improve effectiveness while reducing harm.

Conclusion: Preventing SCD in athletes requires a balanced, evidence-based approach that combines clinical vigilance, ethical safeguards, and practical implementation. Primary care clinicians are central to delivering accessible and equitable strategies that support informed decision-making and early intervention.

ID 2039- Bridging the Distance: Rural POCUS-Based Diagnosis and Co-Management of Non-Immune Fetal Hydrops

Hsin-Hsuan CHUNG, Hung-Keng WU, Yi-Wen TSAI

Department Of Family Medicine, Chang Gung Memorial Hospital, Linkou, No.5, Fuxing St., Guishan Dist., Taoyuan City, 333, Taiwan, New Taipei City, Taïwan

Context: Fatigue is highly prevalent among healthcare workers and is associated with impaired health, reduced productivity, and increased occupational risk. Fatigue assessment using standardized scales may provide a practical approach for identifying workers at risk of functional decline and guiding workplace health promotion strategies. However, its association with objectively measured physical fitness remains unclear in occupational healthcare settings.

Objectives: This study aimed to examine whether moderate-to-severe personal or work-related fatigue, assessed using validated fatigue scales, is independently associated with physical fitness performance, such as muscle strength, muscle endurance, flexibility, cardiorespiratory fitness, and grip strength among hospital employees.

Methods: In this multicenter, cross-sectional study, personal and work-related fatigue were assessed using validated scales, and participants were categorized into mild or moderate-to-severe fatigue groups. Independent t-tests were conducted to compare demographic characteristics and physical fitness parameters between fatigue groups. Multivariate linear regression analyses were performed to examine associations between fatigue severity and physical fitness outcomes, particularly muscle strength and muscle endurance, adjusting for potential confounders.

Results: A total of 365 hospital employees were enrolled, with a mean age of approximately 45 years. Compared with employees reporting mild fatigue, those in the moderate-to-severe fatigue group were significantly younger (43.2 vs. 46.1 years, $p < 0.05$), exhibited poorer muscle strength and endurance as measured by sit-up normative scores (3.54 vs. 3.94, $p < 0.05$), and had lower overall physical fitness scores (11.8 vs. 12.7, $p < 0.05$). After multivariable adjustment, moderate-to-severe fatigue remained independently associated with lower muscle strength and endurance ($\beta = -0.10$; 95% CI: −0.19 to −0.01; $p = 0.026$). Compared with employees reporting mild fatigue, those with moderate-to-severe fatigue demonstrated an approximately 0.1-point reduction in muscle strength and endurance performance.

Discussion: Fatigue severity, assessed using standardized scales, was independently associated with poorer muscle strength and endurance, suggesting that fatigue may capture aspects of functional health status not fully reflected by traditional cardiometabolic or anthropometric indicators.

Conclusion: Fatigue assessment may serve as a scalable and actionable tool for healthcare employers to identify workers at risk of functional decline and to guide targeted workplace health promotion and fatigue management strategies. Keywords (MeSH Terms) Fatigue; Physical Fitness; Workplace Health Promotion

ID 777- Bright beginnings: protecting mothers from postpartum depression

Elif GUNES, Velittin Selçuk ENGIN

University Of Health Sciences Hamidiye Faculty Of Medicine, Istanbul, Türkiye

Context: Family medicine residents work under high clinical workload, emotional demands, and continuous accessibility requirements, which may adversely affect their professional

quality of life. With the integration of smartphones into clinical practice, physicians are increasingly exposed to work-related digital demands beyond working hours. Excessive and problematic smartphone use has been associated with burnout and psychological distress in healthcare professionals; however, evidence focusing on family medicine residents and professional quality of life subdimensions remains limited. Exploring this relationship is essential to support physician well-being in primary care settings.

Objectives: This study aimed to investigate the association between smartphone addiction and professional quality of life among family medicine residents, with a specific focus on compassion satisfaction, burnout, and compassion fatigue.

Methods: This cross-sectional descriptive study was conducted among family medicine residents. Data were collected using an online self-administered questionnaire including sociodemographic characteristics, the Smartphone Addiction Scale–Short Version, and the Professional Quality of Life Scale. Associations between smartphone addiction and professional quality of life and its subdimensions were analyzed using appropriate statistical methods.

Results: A total of 305 family medicine residents were included in the study. Higher levels of smartphone addiction were associated with lower compassion satisfaction and higher levels of burnout and compassion fatigue. Smartphone addiction showed a negative association with compassion satisfaction and positive associations with burnout and compassion fatigue. In multivariate analyses, problematic smartphone use remained independently associated with increased burnout and compassion fatigue.

Discussion: This study contributes to the literature on digital behaviors and physician well-being by demonstrating that smartphone addiction is associated with professional quality of life among family medicine residents. Multivariate analyses suggest that problematic smartphone use may play a role in burnout and compassion fatigue beyond sociodemographic characteristics. These findings are consistent with previous research in healthcare professionals and highlight the relevance of digital exposure in the residency context, where workload and constant connectivity are prominent features of training.

Conclusion: Smartphone addiction was associated with professional quality of life among family medicine residents, particularly with increased burnout and compassion fatigue. These findings underscore the importance of problematic smartphone use in understanding professional well-being during residency

Tom AXELROD, Marina GOLDIN ISSERLIS, Manal MUHAREB

Clalit Healthcare Services And The Hebrew University, Jerusalem, Israël

Context: Narrative Medicine and the field of Medical Humanities highlight the role of literature and writing in understanding the experiences of patients and physicians, fostering reflection, and shaping professional identity. These dimensions are increasingly recognized as essential in medical education, as they contribute to resilience, empathy, and a sustained sense of meaning throughout a medical career. This workshop presents literature as a structured educational tool in family medicine training and professional development.

Objectives: By the end of the workshop, participants will be able to: 1. Practice reflective reading skills using literary texts related to medicine and healthcare. 2. Generate ideas for integrating literature into family medicine education, supervision, and professional development. 3. Explore different literary genres relevant to medical practice. 4. Contribute to the creation of a shared repository of literary resources for family medicine training.

Teaching method and workshop: The workshop will combine guided reading of selected literary texts in small groups with facilitated discussion and collective reflection. Participants will actively contribute to creating a shared repository of literary resources, discussing their releva

Expected outcomes: Participants will gain practical experience in reflective reading, develop concrete ideas for using literature as an educational tool, and deepen their understanding of diverse literary approaches to medicine. The workshop will provide an opportunity to d

Conclusion: Literature is a powerful yet underutilized resource in medical education. By offering a structured and pedagogically grounded approach to integrating literary texts into family medicine training, this workshop aims to enrich educational practice, support professional identity formation, and strengthen reflective and empathic capacities among family physicians.

ID 1882- Building a European Trainer-of-Trainees Network for Point-of-Care Ultrasound in Rural Family Medicine

Gin Juat TAN, Lacey ANG, Ayush JAYAKRISHNAN, Jovern TEO, Lay Hoon GOH

National University Of Singapore, Singapore, Singapour

Context: Preventive services reduce disease burden, yet uptake remains suboptimal among public rental housing residents. Continuous contact with a regular primary care physician may influence preventive services engagement, but this association remains under-characterised in Singapore's rental-flat communities.

Objectives: To examine associations between having a regular primary care physician and uptake of preventive services, including colorectal screening, mammogram, general health screenings, and glucose and lipid screening.

Methods: In 2025, the NUS conducted a community screening among Toa Payoh rental housing residents. Data included self-reported regular primary care physician status and preventive services uptake. Descriptive statistics summarised uptake. Logistic regression assessed associations with colorectal screening or glucose and lipid screening, adjusting for age, gender, and number of chronic conditions.

Results: Among 116 participants (50.9% female; mean age 64.0±10.8), 47.4% reported having a regular primary care physician. 35.6% of 59 eligible females reported mammogram uptake in the past 2 years, 23.3% of all residents reported general health screenings in the past year, 18.1% reported colorectal screening uptake in the past year, and 10.3% reported glucose and lipid screening. Colorectal screening (30.9% versus 6.6%, p=0.0013) and glucose and lipid screening (18.2% versus 3.3%, p=0.0125) were significantly higher among people with a regular physician as compared to those without. There were no associations found for mammogram and general health screenings. Logistic regression showed a regular physician remained strongly associated with colorectal screening (aOR 16.0, 95% CI 3.36-76.46) and glucose and lipid screening (aOR 6.78, 95% CI 1.32-34.71). Older age increased colorectal screening odds (adjusted OR 1.06 per year, 95% CI 1.002-1.12). Female gender was associated with glucose and lipid screening, while chronic conditions were not associated with either outcome.

Discussion: Regular contact with a primary care physician can reinforce health-seeking behaviours, explaining higher colorectal screening and glucose and lipid screening. Weaker mammogram and general health screening associations may reflect accessibility, gender norms, or perceived relevance.

Conclusion: Among public rental housing residents attending a community screening in Singapore, having a regular primary care physician was associated with higher uptake of preventive care.

ID 1229- Building capacity to assess scalability of innovations in primary healthcare for equitable and humanistic impact: Workshop proposal

Alexandre FERRO, Cezzanne ALMEIDA, Eduarda ROSSI, Iasser AYOUB, Hugo RODRIGUES

Faculty São Leopoldo Mandic, Araras, Brésil

Context: Sepsis is a life-threatening condition with significant public health implications. Despite its severity, public awareness remains low. This project aimed to increase community awareness about sepsis while promoting overall health literacy using an innovative active music methodology. The initiative aligns with broader health promotion goals, emphasizing preventive measures and early intervention strategies in primary care settings.

Methods: A community program with primary care clinics used active music to educate about sepsis and health. Weekly workshops over six months had participants create songs guided by healthcare providers and music educators. Surveys measured knowledge and behavior changes.

Originality: The application of active music creation as a tool for comprehensive health promotion in primary care settings, including sepsis awareness, is innovative. This approach differs by actively engaging patients and community members in content creation, potentially increasing retention and fostering a sense of ownership over health information.

Lessons learned and future implications: Key lessons included the effectiveness of integrating specific health topics with broader primary care messages, the importance of culturally adaptive approaches, and the power of peer-to-peer education through music. The project demonstrated the potential of creative arts in enhancing health literacy and patient engagement in primary care. Future iterations could explore integration with electronic health records for personalized follow-ups and assess impact on primary care utilization patterns.

Discussion: The active music methodology proved effective in increasing sepsis awareness and overall health literacy in the primary care context. Post-intervention surveys showed a 40% improvement in sepsis knowledge and a 30% increase in reported preventive health behaviors. Primary care providers reported increased patient engagement and more informed discussions during consultations. The program also led to a 25% increase in timely primary care visits for early signs of infection, potentially reducing late-stage sepsis presentations.

Conclusion: This approach demonstrates the potential of integrating creative arts with primary care initiatives. By making health education more engaging, the project contributes to community empowerment, improved health literacy, and enhanced patient-provider communication in primary care settings. It underscores the importance of holistic, engaging approaches to health education that can lead to more health-conscious communities and more effective primary care interventions.

ID 1108- Building Resilience in Primary Care: A Practical Toolkit for Crisis Preparedness in XXXXX General Practices

Teresa RIBEIRO [(1)], Carolina CORDOVIL [(2)] , Daniel NEVES [(1)], Oxana SECARA [(1)], Paula MAIA DA SILVA [(1)]

(1) Usf Novo Mirante, Lisboa, Portugal
(2) Eyfdm, Lisboa, Portugal

Context: Intrauterine devices (IUD) are a widely used and reliable long-acting contraceptive method, favored for their convenience and cost-effectiveness, and commonly inserted by family physicians in Portugal. Although uterine perforation is one of the most serious complications associated with IUD use, it remains rare and may be clinically silent. Following perforation, the device may migrate and be found in adjacent structures, with ectopic locations reported in the omentum, mesentery, pouch of Douglas, colon, and bladder.

Methods: We report the case of a 39-year-old Portuguese woman (G2P2) who underwent successful placement of a 52-mg

levonorgestrel-releasing IUD on August 9, 2024, during a consultation with her family physician, without complications. Following the procedure, she experienced two days of colicky suprapubic pain accompanied by light vaginal spotting, which resolved spontaneously, and she subsequently remained asymptomatic. Eleven months after insertion, she presented again to her family physician with complaints of menorrhagia. On physical examination, she reported no abdominal pain, and the IUD strings were not visualized. A subsequent transvaginal ultrasound revealed an empty uterus with no trace of the IUD. This prompted further investigation. Plain abdominal X-ray: IUD in an indeterminate location, projecting over the right pelvis. Given this result, a computed tomography (CT) scan of the pelvis was requested for clarification. The CT scan revealed the displaced IUD located in the right iliac fossa. After that, she was referred to hospital. The hospital gynecology team opted for laparoscopic removal of the IUD after imaging confirmed its intra-abdominal position and suggested favorable conditions for minimally invasive retrieval.

Originality: This case highlights the importance of vigilance for mildly symptomatic uterine perforations, which are less commonly reported in the literature.

Lessons learned and future implications: Clinicians should maintain a high index of suspicion for IUD displacement or uterine perforation in women presenting with menorrhagia and no lower abdominal pain.

Discussion: IUD migration is an uncommon complication, immediate or delayed. Diagnosis requires imaging: ultrasound first-line but may miss extrauterine devices; abdominal X-ray helps, while CT provides superior localization and visualization accuracy.

Conclusion: Clinicians should be aware of the possibility of a paucisymptomatic presentation and should consider this diagnosis in IUD users, particularly when new compatible symptoms arise.

ID 424- Bullous Pemphigoid induced by gliptins: Successful management with Dupilumab

Iasser AYOUB, Bárbara BUENO, Felipe PANAINO, Márcio DE MELO, Naila DE OLIVEIRA

Faculty São Leopoldo Mandic, Araras, Brésil

Context: Cardiovascular diseases are a leading cause of mortality globally, including in Brazil, necessitating rapid and effective interventions such as cardiopulmonary resuscitation (CPR). Basic life support (BLS) is crucial for increasing survival rates in cardiorespiratory arrest cases, especially when applied early. Given Primary Health Care's (PHC) role as the health system's gateway, understanding PHC professionals' BLS preparedness is critical.

Methods: This integrative literature review utilized the Virtual Health Library (BVS), EBSCO, Google Scholar, and PubMed platforms, considering publications from 2014 to 2024. The review included 15 relevant studies.

Originality: This review uniquely focuses on PHC professionals' knowledge and performance in BLS, an area not extensively explored in previous literature reviews.

Lessons learned and future implications: The review revealed significant gaps in PHC professionals' BLS preparation. Findings include: 13.33% of studies dealt with BLS simulation scenarios for PHC professionals; 53.33% assessed these professionals' knowledge levels; 13.33% highlighted training and qualification needs; 13.33% discussed lack of organization and adequate materials at PHC units; and 6.66% pointed out professionals' insecurity as a limiting factor. These findings underscore the need for regular training and practical updates to improve healthcare quality and reduce complications from late or inadequate interventions.

Discussion: Results indicate a clear need for improvement in PHC professionals' BLS knowledge and skills. The high percentage of studies assessing knowledge levels suggests recognition of this issue in the field. The identified lack of organization, adequate

materials, and professional insecurity further compounds the problem.

Conclusion: This review highlights significant gaps in PHC professionals' BLS preparation. To address these shortcomings, it is essential to offer regular training and practical updates. Such initiatives would enhance healthcare quality and contribute to reducing complications from delayed or inadequate interventions in emergency situations. Investing in continuous education is crucial to ensure more effective and safe care in cardiovascular emergencies within primary health care settings.

ID 924- Can we reduce microbial burden in frail patient care by dry fog disinfection?

Omar SARI

Samg Algerie, Tlemcen, Algérie

Context: 1 - Difficultés lors de l'abord de la stratégie diagnostique2 - Difficultés de prise en charge.

Objectives: 1.Améliorer l'approche pratique du praticien, devant une adénopathie d'origine tuberculeuse. 2.Améliorer l'éducation thérapeutique du patient en discutant lors de l'annonce du Dc, des effets secondaires des thérapies spécifiques. 3.Repérer les situations cliniques de la pathologie ganglionnaire (tbc, processus infectieux, lymphome…).

Teaching method and workshop: Présentation interactive des adénopathies en générale et de la tuberculeuse en particulier: * Introduction. * Démarcheétiologique pratique (Dc Différentiel) - ACRONYME MIAMI * Démarche diagnostic (Dc Différentiel) * Pathgogénie * Les milieux à risques. *

Expected outcomes: 1°) - Amélioration de la prise en charge d'une TEP dans sa forme ganglionnaire. 2°) - Education thérapeutique du patient. 3°) - IDRt Vs IGRA, quand prescrire? avantages et inconvénients

Conclusion: •Penser à la tbc GGL, chez les patients migrants, immunodéprimés, et les patients âgés en raison d'une réactivation possible de la tuberculose. •L'échographie cervicale avec cytoponction couplée à la coloration de ZN et à la PCR permet une identification rapide de mycobacterium tuberculosis. •La tuberculose ganglionnaire peut répondre lentement au traitement avec le risque de développement de réaction paradoxale chez un grand nombre de patients (20%). L'exérèse chirurgicale initiale a une sensibilité diagnostique optimale et constitue un complément du traitement médical.

ID 1041- Cancer Risk Reduction Associated with Ezetimibe–Statin Combination Therapy in Primary Care

Didem KAFADAR, Sevda SEYRIMEZ, Gunay CAN

Istanbul University-Cerrahpasa, Istanbul, Türkiye

Context: Throughout the course of chronic diseases such as ankylosing spondylitis, many factors affect disease activity and quality of life. Diet and exercise in these patients have been investigated in various studies. In addition, treatment adherence plays a critical role in improving clinical outcomes and quality of life in the management of chronic diseases.

Objectives: This study aimed to evaluate the effects of adherence to the Mediterranean diet(MEDAS), physical activity level, and treatment adherence on disease activity and quality of life in patients diagnosed with ankylosing spondylitis.

Methods: A total of 175 patients followed up with an ankylosing spondylitis diagnosis in the rheumatology outpatient clinic of the hospital participated in the study. Mediterranean Diet Adherence Scale, the International Physical Activity Questionnaire–Short Form, the Compliance Questionnaire for Rheumatology,and the Bath Ankylosing Spondylitis Disease Activity Index were utilized and sociodemographic data and disease history were gathered through face-to-face interviews.

Results: The study group consisted of 40.6% women. The mean age of participants was 44.6 ± 10.7 years, and a positive and significant correlation was found between age and

adherence to MEDAS (r =0.246, p = 0.001). Individuals with higher physical activity levels had significantly lower MEDAS scores (p = 0.027). A positive and significant correlation was found between treatment adherence and adherence to the MEDAS (r = 0.203, p = 0.012). Women had significantly higher disease activity than men(p<0.001).Among socioeconomic variables, active employment status (p= 0.038) and monthly income level (p = 0.045) were significantly associated with disease activity. Quality of life scores were higher in the low-income group (p < 0.001) and in those with chronic comorbidities (p = 0.020).

Discussion: Overall, this study revealed that disease activity in patients with ankylosing spondylitis is influenced by sociodemographic factors such as sex, income level, employment status, and presence of chronic disease. Older individuals and those who were adherent to treatment showed better Mediterranean diet adherence.

Conclusion: The findings of thi study emphasize that in the management of the disease, attention should be paid not only to medical treatment but also to patients' sociodemographic characteristics, lifestyle factors, and treatment adherence.

ID 1404- Cardiac alterations following an electric shock

Lourdes Erika RODRIGUEZ

San Lazaro Hospital Manila, Manila, Philippines

Context: Human Immunodeficiency Virus (HIV) is a virus that attacks the body's immune system. Malnutrition is one of the complications of HIV infection and may lead to the development of opportunistic infections and death. Evaluation and enhancement of patients' nutritional status may help correct deficiencies and help in the treatment of HIV. Keywords: HIV, Malnutrition, Antiretroviral Drug

Objectives: This study assessed the nutritional status of newly diagnosed HIV patients prior to antiretroviral drug treatment at a tertiary hospital from March 2024 to December 2024.

Methods: This is a prospective descriptive study which included newly diagnosed HIV patients without prior antiretroviral drug therapy enrolled in the outpatient department, males and females aged 19 to 59 years old with no known comorbidities. Anthropometric data were collected using Body Mass Index (BMI), Mid-upper-arm Muscle Area (MAMA) and Skinfold Thickness (SFT). Nutritional risk was determined using Nutritional Risk Screening 2002 (NRS-2002), and dietary intake was assessed using 24-hour Food Recall with the Food Exchange List as guide. Purposive sampling method was used. Sample size was computed using Raosoft sample size calculator with 95% confidence interval and margin of error of 5%. A z-test was performed to determine if the sample population (N=80, using a population size of 100) is meeting the energy requirements and if it meets the national reference standards.

Results: The highest mean score was observed in the 24-hour Food Intake, indicating that energy intake was relatively higher than the other metrics. In contrast, the lowest mean was found in Nutritional Risk Screening 2002 suggesting that most respondents were not at immediate risk of malnutrition according to clinical criteria.

Discussion: Assessment of nutritional status through standardized tools showed majority of patients were classified as low risk according to Nutritional Risk Screening 2002. A considerable proportion exhibited undernutrition based on BMI and Triceps Skinfold measurements.

Conclusion: There is an urgent need for early nutritional assessment and intervention among HIV patients, even before ART initiation, as undernutrition could compromise immune function and treatment outcomes. Future programs should consider targeted nutritional support alongside antiretroviral therapy to improve patient prognosis and quality of life.

ID 1325- Cardiac alterations following an electric shock

Sigrid LATT, Lona-Liisa PRUKS

Nope, Tallinn, Estonie

Context: Craniosynostosis is one of the most common head and facial malformations. Craniosynostosis is the premature ossification of one or more of the sutures of the skull, which can result in an abnormal shape of the skull or its slower development. Early diagnosis of craniosynostosis is crucial, as delayed diagnosis may lead to increased intracranial pressure, potentially resulting in severe complications such as brain injury and vision loss.

Methods: A male baby was delivered at full term (40+6) via a planned caesarean section with APGAR scores of 9/9, birth weight 4010 g, and head circumference 38 cm. The mother first noticed a visible 1 cm long prominence along the sagittal suture at 10 days of age, which increased progressively over time. The mother requested a referral to a specialist at the 1-month checkup. The patient was seen at 2 months of age – a bony ridge was palpable along the entire sagittal suture, accompanied by scaphocephaly. At 4 months, the diagnosis was confirmed radiographically. The patient underwent cranioplasty at 4.5 months of age. There was no family history of skeletal deformities. At 6 months of age, the infant's psychomotor development was within normal limits.

Originality: Cases in XXX are rare, with approximately 12 diagnoses made in a year. Optimal timing is also complicated by the narrow age gap (ideally 6–12 months) best for treatment. This case illustrates how timely action can prevent more serious complications.

Lessons learned and future implications: Mothers of newborns seek more and more advice during health checkups for various (often minor) concerns. This decreases a physicians' ability to distinguish what is important. In this case, it is worth bearing in mind that a mother's instinct can still be trusted.

Discussion: Would a parent without a medical degree have been able to react as quickly? How should family physicians cope with the ever-increasing number and prevalence of rare diseases? Which rare pediatric conditions should be prioritized in medical education to improve early recognition and management?

Conclusion: In XXX, the main challenges for children with craniosynostosis include delayed diagnosis, low awareness among family doctors, and a shortage of specialists in this field (only one surgeon available).

ID 2032- Caring Without Collapse: Karoshi in General Practice

Angelina PACE

Faculté De Médecine De Strasbourg, Strasbourg, France

Context: Although healthcare systems promote equality and universal access to care, women's care pathways remain permeated by sexist violence rooted in gender stereotypes. These biases can infiltrate everyday clinical encounters and lead to discrimination, loss of trust and, in some cases, medical violence. While research on obstetric and gynecological violence has expanded in recent years, medical violence experienced by women across healthcare settings remains insufficiently explored, particularly from the perspective of primary care.

Objectives: To describe and analyse forms of medical violence linked to gender stereotypes as experienced by women throughout their care pathways.

Methods: A qualitative study was conducted in 2020-2021 using twenty semi-structured interviews with adult French-speaking women. Participants were recruited via social media and snowball sampling. Interviews explored experiences of care across different medical settings. Data were analysed using a phenomenological thematic approach, with double coding and triangulation to enhance analytical rigor.

Results: Analysis led to the development of a "pyramid of medical violence," ranging from the trivialization of sexism to explicit forms of violence embedded in rape culture. Intermediate levels included derogatory remarks, sexist discrimination in research and clinical practice, reification of patients and deprivation of autonomy. Participants frequently reported a sense of dispossession of their identity, body and healthcare decisions. These experiences were linked to societal injunctions surrounding "femininity," internalized sexist norms and normative control over reproductive health. Consequences included resignation, avoidance of male healthcare providers and, in some cases, renouncement of medical care. Conversely, some women developed coping strategies based on solidarity, peer support and empowerment.

Discussion: Findings are consistent with existing literature and highlight medical violence as a systemic phenomenon rather than the result of isolated individual behaviors. Limitations include potential selection bias related to voluntary participation, as well as recall and social desirability biases. However, the qualitative design allowed for in-depth exploration of lived experiences that remain largely invisible in clinical practice.

Conclusion: Gender stereotypes significantly shape women's care pathways and can generate forms of medical violence. Raising awareness among healthcare professionals, particularly in general practice, is essential. Integrating training on gender bias, intersectionality and patient participation into healthcare education appears necessary to foster compassionate, trust-based care environments.

Michaël ROCHOY [(1)] , Sarah CUMPS [(2)], Camille HONG [(3)]

(1) Univ. Lille, Outreau, France
(2) Centre Académique De Médecine Générale, Louvain, Belgique
(3) Univ. Paris, Paris, France

Context: General practitioners face increasing administrative demands, some of which have little medical value ("absurd certificates"). These administrative demands reduce the time available for medical care, while population needs continue to rise. Requests originate from private insurers, employers, schools, sports clubs, public institutions, etc. These requests vary from country to country, but share several mechanisms: transfer of responsibility to doctors ("controllers" rather than caregivers), lack of legal basis, and erosion of access to care. In response, Belgian and French Colleges of general practitioners have launched the websites certificats-absurdes(.be and .fr) combining several initiatives to identify, document, challenge abusive certificate requests and, where relevant, advocate for legislative change.

Objectives: The workshop aims to share concrete experiences from France and Belgium in identifying and reducing excessive requests for medical certificates; present practical tools and strategies; encourage discussion on the transferability of these initiatives to European primary care systems; and build a European network aimed at reducing low-value-added administrative tasks.

Teaching method and workshop: The teaching method will involve active participation, peer exchanges and practical examples. The workshop will be co-facilitated by Belgian and French experts on these topics, with the following schedule: 10min: Interactive introduction: participants sha

Expected outcomes: Participants will acquire practical skills to identify abusive certificate requests, respond to them with sound legal arguments, and take action at local or national level. The workshop will establish common principles and a preliminary roadmap for po

Conclusion: This workshop draws on real-life experiences to address a common issue in European primary care, responsible for a massive loss of medical time. By sharing our tools, results and lessons learned from French and Belgian experiences, we aim to promote evidence-based strategies to reduce

administrative overload and give back medical time to general practitioners across Europe.

ID 1259- Case report: Persistent hematuria

Fernanda PIRES DILLY [(1)], Felipe ALVES DOS SANTOS [(2)]

(1) Fiocruz, Barra Do Piraí, Brésil
(2) Icepi, Vitória, Brésil

Context: In the current Brazilian public health scenario, medical qualification is one of the pillars for strengthening the Unified Health System (SUS). In this landscape, the lato sensu public specialization program in Family and Community Medicine (FCM) stands out as a large-scale initiative covering the vast and heterogeneous national territory. The complexity of this proposal requires a pedagogical structure that combines academic robustness with the flexibility necessary to adapt to regional singularities and the local demands of Primary Health Care (PHC).

Methods: Structured as an online distance learning program, the methodology relies on the medical tutor to bridge theoretical knowledge and professional practice. Continuous monitoring ensures that participants develop essential FCM competencies integrated into their specific healthcare contexts.

Originality: The report's originality lies in redefining the tutor as an active agent of transformation rather than mere technical support. This shift uses technology to ensure pedagogical capillarity, extending high-quality specialization to remote areas and democratizing medical knowledge through empathetic, human mediation.

Lessons learned and future implications: Experience shows that online tutoring enhances accessibility and knowledge exchange across diverse Brazilian realities, enriching clinical practice. However, student isolation and low engagement remain persistent challenges, often worsened by technological barriers. This underscores the need for a tutorial presence that is not only instructive but also motivating and welcoming.

Discussion: Reflecting on teaching practice reveals that tutoring in FCM requires a professional in a constant state of "construction." The discussion involves the need to overcome the traditional teaching paradigm and adopt a dialogic posture, where the tutor uses digital tools to mitigate physical distance and create bonds of pedagogical trust. The quality of primary care is directly linked to this tutor's ability to transform technology into a tool for humanization and technical qualification.

Conclusion: In conclusion, the medical tutor is indispensable to the success of large-scale programs. Future efforts must prioritize continuous professional development for tutors, focusing on engagement strategies and new educational technologies. The goal remains to maximize digital resources to ensure medical training translates into higher quality health care for the Brazilian population.

Context: There are many situations in which family doctors need to expand their medical activity: buying either a new diagnostic tool, or a new building, or hiring more staff, or others. In these situations, even having a good financial reserve, it may be smart to use credit. The use of credit is nearly unavoidable among doctors who are self-employed or who are partners in a medical society. A smart use of credit may boost incomes and may allow to achieve the goals. An erroneous use of credit may lead to a disaster. No use of credit may be a loss of opportunities.

Objectives: To provide an overview of the essential financial concepts adapted to family

doctors To explain different types of financial credit instruments (mortage, loan, pledge...) To show the best way of using credit in different situations To analise essential financial indicators To increase the financial knowledge of the participants applied to family medicine

Teaching method and workshop: 1- Theoretical introduction: 15 minutes We will explain the essentials of finance for doctors. We will introduce the exercise to be done by the attendants in groups. 2- Practical exercise to be done in small groups of 5 people: 20 minutes The exercise w

Expected outcomes: To increase the financial knowledge of the participants To provide practical skills related to the use of credit To show how to avoid common mistakes To identify real day-to-day situations in which credit may be used To manage basic financial indicato

Conclusion: Credit may be used in a significant number of situations in our daily life. Family doctors should have a good knowledge of credit management. A smart use of credit leads to a successful medical activity.

(3) Julius Center, Julius Center, Dept. General Practice & Nursing Science Circulatory Health Infection & Immunity, Utrecht, Pays-Bas

Context: A process of defining the Core Values of General Practice/Family Medicine (GP/FM) has been going on for a few years. It started in some European countries, later on at a WONCA Europe level and now on a WONCA World level. The project now enters its second phase which will integrate the core values into training of the discipline of GP/FM. The authors of this workshop have been and are still part of this global project.

Objectives: Our values and the principles of GP/FM are the cornerstones of our discipline. Teaching of these values are essential for medical students, for doctors in training for GP/FM and the values should also be an integrated part of professional development for family doctors. We will explore how well values and principles are integrated in teaching at all 3 levels across Europe. Practices and standards wary across European countries due to different contexts (local needs, public expectations and demands versus available resources), but still the cornerstones are part of the same foundation. Exchanging teaching and training methods of these core values in different settings will inspire participants in implementing new methods in their own settings.

Teaching method and workshop: Teaching methods: Short lecture, small group discussion and plenary discussion. Workshop schedule: Introduction with an overview of WONCA Core Values project (10 minutes) Group discussion which aims to share experiences and strategies for change Plenary w

Expected outcomes: Participants will get a broader knowledge about the WONCA Core Values project – and how to implement the values and principles of our discipline into medical teaching and training.

Conclusion: Defining the core values of GP/FM was first step – second step is to secure teaching and training of these defined values of our discipline.

(4) Universidad De O'higgins, Rancagua, Chili

(5) Nova School Of Science And Technology, Lisbon, Portugal
(6) Norwich Medical School, Norwich, Royaume-Uni

Context: Primary healthcare is the biggest healthcare activity globally, with pervasive evolving issues that require ethics support and education. And for a number of reasons it is a poorly served speciality in terms of ethics support and education, which often resides in institutions disconnected from the primary healthcare environment. The WONCA Working Party on Ethics and Professionalism, in collaboration with the Working Parties on Education, Policy and Advocacy, Family Violence, Emergency medicine and Quality and Safety, has been awarded seed funding to develop an ethics support and education model for primary healthcare globally. We have identified a list of pilot countries: Australia, Chile, Portugal, South Africa, and the UK. We aim for a mutally informative roundtable discussion with WONCA Europe delegates who by default represent a key stakeholder group.

Objectives: The WONCA Working Party on Ethics and Professionalism will use the workshop to showcase the clinical ethics support project so far, and illustrate this using our pilot countries: Australia, Chile, Portugal, South Africa, and the UK. Delegates will learn about ethics support and education as it currently exists in these countries for primary healthcare. We also aim to discuss: the literature, modes of support and education, training for ethics facilitators, what institutions might take on ethics support, and how we might reach appropriate policymakers, policy workers and publics to ensure that we offer effective supportive and sustainable structures. We will discuss costs of such activities, risks, governance and other practical aspects of ethics support around the world. We expect that the discussion will be useful to all primary healthcare leaders and educators, as well as clinicians considering where they might access support in their own institutions.

Teaching method and workshop: Brief discussion of the WONCA clinical ethics support project. Round-table discussion with delegates

Expected outcomes: We will report on what we know so far from pilot countries as a knowledge exchange opportunity The discussion will also inform the WONCA clinical ethics support project

Conclusion: We expect that the discussion will be useful to all primary healthcare leaders and educators, as well as clinicians considering where they might access ethics support and education in their own institutions.

No, Madrid, Espagne

Context: A 29 years female patient pressented to her family physician with a big unilateral cervical lymphadenopathy of two weeks of evolution. She refers fever at the begining of the episode after catching a cold with a maximum body temperature of 38º with sore throat, in treatment with antipyretics with resolution of the fever but pain in lymph node. On the first examination, the patient had no fever, and had multiple and painful lymphadenopathies in the right side of the neck. No adhesion to the surrounding tissue. No hepatomegaly or splenomegal. No weight loss, no travels, no family illness.

Methods: The ultrasound in primary care evidence: multiple enlarged lymph nodes in the right cervical upper jugular measuring the largest 45x15mm. Blood examination laboratory tests showed a white blood cell count of 2,5x109 L, C reactive protein 9,43 mg/dl Lymph noce escisional biobsy showed numerous lymphohistiocytic cells, multiple necrotic areas with marked karyorrhexis and prolifetation of histiocytes, The diagnosis was: Kikuchi-Fujimoto disease

Originality: Kikuchi-Fujimoto disease is a rare, bening, self-limited disorder characterized by

subacute or acute cervical lymphadenopathy, often accompained by fever, predominantly in young adults of Asian descent bit reported worldwide The etiology ramains unclear, bt current evidence implicates an aberrant immune response, possibly triggered by viral infection or autoimmune mechanisms, with a predominance of CD 8 T cells and plasmacytoid dentritic cells in affected lymph nodes. Diagnosis is established by escisional lymph node biopsy, which reveals characteristic paracortical necrosis with abundant karyrrhectic debris, proliferation of histiocytes, and absence of neutrophils and eosinophils.

Lessons learned and future implications: The clinical and histopathologyfical features can mimic lymphoma and systemic lupus erythematosus, making accurate disgnosis essential to avoid unnecessary or inappropriate therapy.

Discussion: Treatment is primarily supportive, as the disease typically resolves spontaneously within 1-4 months. Nonsteroidal anti-inflammatory drugs and analgesics are first-line for symptom control. Corticosteroids may be considered in severe or persistent cases. Long-term follow up is recommended due to small but subnotable risk of subsequent development of lupus erythematosus.

Conclusion: Accurate clinicopathologic recognition is crucial, particulary because it can be mistaken for malignant lymphoma

Beatriz LOPEZ SERRANO, Sandra María HURTARTE ARROYO, Pedro MEDINA CUENCA, Rayrinne Karina MARMOLEJOS DEL ROSARIOO, Angie SIERRA TAMAYO, Sara FERNANDEZ BRAVO, Macarena NUÑEZ CUETO, Adrian WOJCIK HAMZA, Eva DE SANTIAGO CORTES, Susana PELAYO VELAZQUEZ

No, Madrid, Espagne

Context: A 31-year-old male patient, with no relevant personal medical history, who comes to his primary care physician reporting having noticed a lump in his left testicle for the past 3 weeks. No local pain, no urinary symptoms, no prostatic syndrome, no fever, no weight loss. His family physician discover after on physical examination, a large, hard mass is palpable in the left testicle. No inguinal lymph nodes are palpable. An ultrasound performed in primary care detected a large homogeneous and hypoechoic mass that occupies almost the total left testicle. A body CT scan was performed, which did not show distant metastatic disease A left orchiectomy was performed, and the anatomopathological study revealed a testicular seminoma. ..

Originality: Seminoma is a malignant germ cell tumor of the testis, accounting for approximately half of all testicuLar germ cell tumors. It typically presents as a unilateral testicular mass in men aged 30-40 years, and its high sensity to radiotherapy and chemotherapy, with an excellent long-term survival rate.

Lessons learned and future implications: Diagnosis is established by physical examination of the testes and scrotal ultrasonography showing an homogeneously hypoechoic intratesticular mass, and confirmed by histopathology following radical inguinal orchiectomy. Pure seminoma does not elevate Alpha fetoprotein. B-human chorionic gonadotropin may be midly elevated in up to 30% of cases. Scrotal ultrasound has a sensitive and specificity > 90% for distinguishing malignant from benign masses

Discussion: Staging with computed tomography of the chest, abdomen and pelvis is recommended to assess for metastatic diseasee. Radical inguinal orchiectomy is both diagnostic and therapeutic. Histopathological assessment of the orchiectomy specimen confirms seminoma. Percutaneous biopsy is contraindicated due to risk of tumor seeding.

Conclusion: A seminoma should be suspected in any male, typically aged 30-40 years, , presenting with a painless, unilateral testicular mass, or with extratesticular symptoms such as abdominal mass, gynecomastia, or supraclevicular lymphadenopathy, especially if

risk factors like cryptorchidism or family history of testicular cancer are present.

No, Madrid, Espagne

Context: Pancreatic cancer is a highly deadly malignant neoplasm and a major public health problem due to its high mortality rate. It is the fourth leading cause of cancer death in developed countries, and its incidence is gradually increasing, potentially becoming one of the top three causes of cancer death. The only curative treatment is surgery, but only 15% of patients are candidates because the disease is usually diagnosed at an advanced stage. Rarely occurs in young patients. The median age is between 65 and 69 years for men and between 75 and 79 years for women.

Methods: A 72-year-old female patient with a history of hypothyroidism, fibrosing alopecia, and hypertension presented with a three-week history of changes in bowel habits (loose stools) without abdominal pain or weight loss. After normal blood work and stool culture, persistent symptoms prompted a positive fecal occult blood test. During the evaluation, and while awaiting gastroscopy and colonoscopy, the patient developed sudden, painless jaundice of 48 hours' duration

Results: Urgent blood work revealed an obstructive cholestatic pattern (bilirubin 7 mg/dL, GGT 1035 U/L, transaminases >500 U/L). An abdominal ultrasound identified a solid mass in the head of the pancreas, a diagnosis confirmed by PET-CT and ERCP biopsy, with histopathological results showing pancreatic adenocarcinoma.

Discussion: This clinical case demonstrates that diagnosis is often delayed due to the presentation of nonspecific symptoms, such as the change in bowel habits initially observed in this case. The current diagnostic standard is multidetector computed tomography with a pancreatic protocol to define resectability based on involvement of the mesenteric vessels and the celiac trunk. ERCP not only allows for biopsy sampling but is also essential for biliary palliation through stent placement. The approach can be summarized as systemic medical treatment: modified FOLFIRINOX neo/adjuvant Gemcitabina/Nab-placitaxel, and curative surgery: pancreaticoduodenectomy (Whipple). The prognosis is good, with a 5-year survival rate of 12-13%, and R0 resection being the most significant prognostic factor.

Conclusion: Given the short survival rate, rapid resistance to treatments, and high mortality, further research is needed at various levels to achieve: earlier diagnoses, more specific and effective follow-up, and improved disease prognosis.

ID 2228- Cervical cancer screening in primary care: adherence and barriers identified during a mass screening initiative

Sena GULSOY, Zeynep PEKEL, Vildan MEVSIM

Dokuz Eylul University, Faculty Of Medicine, Department Of Family Medicine, Izmir, Türkiye, Izmir

Context: In primary care, patients frequently attribute weight loss and palpitations to stress or anxiety, especially during psychosocially demanding periods. While psychological explanations are common, premature attribution may delay recognition of underlying organic disease. This case illustrates how hyperthyroidism was uncovered after reassessing symptoms initially framed as anxiety-related.

Methods: A 34-year-old woman presented to a family medicine clinic requesting help for “stress-related weight loss and anxiety.” She reported fatigue, sleep disturbance, intermittent palpitations, and a 7-kg unintentional weight loss over three months. She had no prior chronic illness or regular

medication use. The patient initially linked her symptoms to work-related stress and caregiving responsibilities. On focused review, she also described heat intolerance and discomfort in warm environments. Physical examination revealed resting tachycardia (102 bpm) and fine tremor, without palpable goiter. Given the discordance between psychosocial attribution and physical findings, targeted laboratory tests were ordered. Results showed suppressed TSH (<0.01 mIU/L) and elevated free T4 (3.1 ng/dL), consistent with hyperthyroidism. The patient was promptly referred to endocrinology for definitive management.

Originality: This case reframes hyperthyroidism as a condition masked by patient-led psychosocial interpretation rather than physician oversight, highlighting a subtle diagnostic trap in primary care.

Lessons learned and future implications: Non-specific symptoms attributed to anxiety warrant structured reassessment. Simple examination findings and basic laboratory tests can prevent diagnostic delay.

Discussion: Hyperthyroidism and anxiety share overlapping features. Anchoring on psychosocial explanations may obscure endocrine pathology unless actively challenged.

Conclusion: Primary care physicians play a key role in re-evaluating symptom narratives. Unintentional weight loss accompanied by tachycardia should prompt thyroid testing, regardless of apparent psychosocial context.

ID 2036- Chagas disease: using a non-invasive biomarker to identify diagnosis

Anaïs SOCKALINGUM, Judith OLLIVON

Dr, Lille, France

Context: In XXX, contraception, legalized in 1967, was rapidly medicalized and predominantly assigned to women. Initially perceived as an emancipatory advancement, contraception became embedded in a "contraceptive norm" assigning near-exclusive responsibility to women.

Objectives: This study aims to explore and model men's perceptions of the contraceptive burden and their involvement within heterosexual couples, in order to improve physician–patient communication in primary care.

Methods: This qualitative study was informed by grounded theory methodology. Adult male participants were recruited from primary care practices in north XXX. Interviews were semi-structured guided by an iterative interview guide, and continued until data saturation. Interviews were recorded, fully transcribed, and analyzed using Excel software. A total of 12 adult men were interviewed, with a mean age of 39 years and a mean interview duration of 25 minutes. Seventy percent of the data were triangulated.

Results: Men acknowledged the existence of costs, constraints, and tasks, defining the concept of "contraceptive burden." Four interrelated dimensions were identified: cognitive or mental (anticipation, information seeking), bodily (physical and psychological side effects), organizational or logistical (scheduling appointments, allocating time), and financial (out-of-pocket expenses for consultations and contraceptive methods, or indirect costs).Four male profiles emerged: distant men (low involvement), fluctuating men (involvement varying across relationships), relational men (long-term engagement), and individualistic men (seeking personal control).

Discussion: This study addresses a rarely explored gender inequality in medicine using an appropriate qualitative methodology. Its limitations include self-reporting bias and the absence of users of innovative male contraceptive methods.

Conclusion: The findings highlight the central role of the general practitioner in promoting male responsibility and supporting couple balance regarding the contraceptive burden, particularly through dedicated consultations.

ID 604- Challenges in diagnosing myasthenia gravis: a case report

Sena GULSOY, Yasemin ÖZKAYA, Vildan MEVSIM

Dokuz Eylul University, Faculty Of Medicine, Department Of Family Medicine, Izmir, Türkiye, Izmir, Türkiye

Context: Tinea corporis is a common dermatophyte infection, frequently transmitted through contact with infected animals. When treated inappropriately with corticosteroids, its classical features may be masked, resulting in tinea corporis incognito. In primary care, distinguishing steroid-modified infections from chronic inflammatory dermatoses is essential to avoid diagnostic delay.

Methods: A 27-year-old female pharmacist with a known history of psoriasis presented with widespread annular plaques on the trunk and extremities. Notably, she reported no pruritus. She had self-administered oral methylprednisolone (16 mg/day) for presumed psoriasis flare. One week before symptom onset, she had adopted a stray cat. Physical examination revealed erythematous plaques with atypical morphology. Given treatment failure and exposure history, fungal infection was suspected. Mycological assessment supported tinea corporis incognito. Systemic corticosteroids were discontinued, and oral terbinafine (250 mg/day for 28 days) with topical luliconazole was initiated, resulting in complete clinical resolution.

Originality: This case highlights the “healthcare professional–patient paradox,” where self-diagnosis and inappropriate steroid use masked a zoonotic infection, delaying correct diagnosis.

Lessons learned and future implications: Family physicians should maintain diagnostic vigilance when chronic skin diseases present atypically or fail to respond to immunosuppressive therapy. Detailed environmental and exposure history is crucial.

Discussion: Systemic corticosteroids suppress inflammatory responses, eliminating hallmark symptoms such as pruritus and altering lesion morphology. In patients with known dermatologic disease, new or changing patterns should prompt reconsideration of the diagnosis. Primary care continuity enables critical reassessment beyond prior labels.

Conclusion: Tinea corporis incognito should be considered when presumed inflammatory dermatoses worsen under corticosteroid therapy. Family physicians play a key role in recognizing masked infections through holistic assessment and continuity of care.

ID 534- Challenges of informing and raising awareness among general practitioners on end-of-life issues

Rayrinne Karina MARMOLEJOS DEL ROSARIO, Beatriz LOPEZ SERRANO, Anggie Lizzethe SIERRA TAMAYO, Sandra Maria HURTARTE ARROYO, Gabriela GONZALEZ LEAL, Maria Victoria JORGE CONTRERAS, Susana PELAYO VAZQUEZ

No, Madrid, Espagne

Context: A 30-year-old male with no relevant medical history presented with a 24-hour onset of dyspnea. He reported recent alcohol and cocaine use over the weekend. He denied fever or previous trauma.

Objectives: To determine the etiology of sudden dyspnea in a young patient without classic risk factors, emphasizing the relevance of substance use history in the diagnostic process.

Methods: The evaluation began in Primary Care (93% oxygen saturation, pathological lung sounds). A point-of-care lung ultrasound revealed an image compatible with a pulmonary infarction. To confirm the findings, the patient was referred to the hospital for D-dimer testing and a CT pulmonary angiogram (CTPA).

Results: The CTPA confirmed a bilateral pulmonary embolism (PE), and laboratory tests showed elevated D-dimer levels. After ruling out differential diagnoses such as pneumonia, pneumothorax, or myocarditis, the thrombotic origin was confirmed.

Discussion: Cocaine exerts a direct vasoconstrictive effect on the pulmonary

endothelium, facilitating thrombus formation even in the absence of comorbidities. In young patients, isolated dyspnea following substance use should raise suspicion of vascular events, as cocaine acts as a potent thrombotic trigger.

Conclusion: This case highlights the critical role of Primary Care in the early detection of life-threatening conditions. Cocaine use is an independent risk factor for PE. The patient was stabilized with anticoagulant therapy and outpatient follow-up.

Corresponding author: Rayrinne Karina Marmolejos Del Rosario, rayrinne30@gmail.com

ID 1299- Changes in Clinical Supervision During Emergency Shifts After National Resident Advocacy Efforts: Preliminary Results from the 2026 Spanish Follow-Up Survey

Charlotte GOOLAERTS [(1)] , Thomas FIERLING [(2)]

(1) Aix-Marseille University, Villeneuve-Lez-Avignon, France
(2) Aix-Marseille University, Aix-En-Provence, France

Context: In 2019, a global appeal was launched by WONCA, inviting general practitioners to take action for planetary health (PH). Four years after this call, what are GPs doing to promote PH?

Objectives: To describe the opinions of GPs about this subject and the prevalence of pro-PH actions in general practice and to evaluate their knowledge of PH.

Methods: According to the STROBE guidelines, we conducted a quantitative cross-sectional study by distributing an online questionnaire. This questionnaire was distributed by email to general practice networks. Responses were analyzed according to role and demographic data using descriptive statistics.

Results: The 974 participants placed significant importance on ecology in their personal lives (mean = 7.1/10) and were relatively aware of the environmental impact of health care. In their professional lives, the importance placed on ecology was lower (mean = 5.80/10). Only 23.1% (n=225) reported being trained during their medical education. During consultations, among the advice that provided both health and environmental cobenefits, the most frequently given were those with a direct benefit to patients' health. The lack of time (n=676, 69.4%) was the first barrier to integrating PH into practice, and the second barrier was the lack of knowledge (n= 606, 62.2%)

Discussion: Our study highlights a significant gap between general practitioners' strong personal interest in environmental issues and the limited integration of PH principles into clinical practice. PH-related actions remain largely ad hoc, focusing mainly on patient health benefits rather than environmental impact. Major barriers include lack of time, insufficient training, feelings of powerlessness, and the perception of PH as a politicized topic. Nevertheless, GPs express genuine interest and concern about their role in PH. The literature emphasizes their responsibility to lead by example for patients and colleagues, as practice managers and decision-makers. Consistent with previous studies, a discrepancy persists between personal commitment and professional implementation.

Conclusion: GPs are citizens who are sensitive to environmental issues, but they are more detached from these issues in their professional lives. It seems crucial to strengthen prevention efforts and integrate environmental considerations into training programs and health policies to create the conditions necessary for this change in practice.

ID 52- Characteristics and healthcare utilization of Long COVID patients included in the care trajectory post-Covid-19.

Muhammet AVCI [(1)] , Esra SAATÇI [(2)]

(1) Erzurum Provincial Health Directorate, Erzurum, Türkiye
(2) Department Of Family Medicine, Faculty Of Medicine, Çukurova University, Adana, Türkiye, Adana, Türkiye

Context: Ageism has been defined as "the expression of prejudice against older individuals through attitudes and behaviors".

Assessing medical students' attitudes towards elderly is critically important to ensure that elderly receive comprehensive and non-discriminatory care in family medicine practice.

Objectives: The aim of this study is to assess and compare attitudes of medical students towards elderly in Adana, Türkiye.

Methods: The first, third and sixth year medical students in Çukurova University Faculty of Medicine in 2023-2024 academic year were enrolled. Sociodemographic Data Collection Questionnaire and Kogan's Attitudes Toward Old People Scale (KOPS) were used. Data were analyzed using SPSS package program version 23.0.

Results: Of 571 students with a mean age of 21,7±3,1 years, 241 (42,2%) were male, 324 (56,7%) were female. The mean KOPS total score was 98.0±14.3. A significant decrease in KOPS scores was observed as students' ages increased ($p<0.001$). The KOPS scores of students with no experience about elderly were significantly higher than those with experience ($p=0.003$).

Discussion: Our KOPS score findings were similar to those found by Özerdoğan et al. (2022), Kavuran and Caner (2021), Turan et al. (2016), Yazıcı et al. (2016), and Adıbelli et al. (2013) However, scores found by Koca et al. (2020) and Sarı et al. (2019) were higher than ours (more positive attitude) whereas scores reported by Salman et al. (2015) were lower. The discrepancy may be due to sociodemographic and geographical characteristics of the studies (more negative attitude).

Conclusion: Our findings indicate that the awareness of family physicians regarding elderly health and discrimination against the elderly needs to be improved starting from basic medical education.

ID 1064- Chest pain and fever: It's not always myopericarditis

Vildan MEVSIM [(1)] , Gizem LIMNILI [(1)], Sude Nur KOMUR [(2)], Uzay Cevik KANTEKIN [(2)]

(1) Dokuz Eylul University, Faculty Of Medicine, Department Of Family Medicine, Izmir, Türkiye
(2) Dokuz Eylul University, Department Of Computer Engineering, Izmir, Türkiye

Context: Ageing populations and the growing burden of chronic diseases place increasing pressure on primary care services. Older adults often face barriers such as limited health literacy, reduced digital skills, mobility constraints, and fragmented follow-up, which may impair self-management and continuity of care. Innovative, user-friendly digital solutions are needed to support elderly patients while reducing general practitioner (GP) workload and promoting equitable access to care.

Objectives: To describe the development and intended functionality of a Virtual Reality (VR)–assisted artificial intelligence (AI) chatbot designed to support chronic disease self-management among elderly patients in primary care.

Methods: This study presents the conceptual design and technological architecture of a VR-assisted AI chatbot developed for use in primary care settings. The system integrates three core components: (1) an AI chatbot that supports daily symptom reporting, medication reminders, and decision guidance; (2) a VR-based education module that delivers simplified, immersive health education tailored to elderly users; (3) a clinician dashboard that summarizes patient-reported data and flags potential risks. The design process was informed by anticipated needs of elderly patients and primary care clinicians, focusing on accessibility, simplicity, and low cognitive load. The system is intended to collect structured patient input and generate concise summaries for healthcare professionals, rather than replace clinical decision-making.

Results: The resulting platform enables daily remote monitoring, reinforces treatment adherence, and provides interactive education aimed at improving patient engagement and self-efficacy. From the clinician perspective, the system is designed to reduce administrative burden by filtering routine data and highlighting patients who may require active follow-up.

Discussion: Unlike conventional digital health tools, the integration of VR aims to overcome educational and motivational barriers commonly observed in older adults. The combination of AI-supported interaction and immersive education represents a novel approach within primary care–based chronic disease management.

Conclusion: This VR-assisted AI chatbot represents a promising technological innovation to support elderly patients in primary care. By enhancing self-management and streamlining clinician workflows, the system has the potential to improve continuity, efficiency, and equity of care. Future studies will evaluate user experiences, clinical integration, and real-world impact.

ID 1755- Chronic brucellosis and obstacles in diagnosis

Ahmet EMIN, Didem KAFADAR

Istanbul University Cerrahpasa, Istanbul, Türkiye

Context: The widespread use of smartphones has become an integral part of daily life among medical students, raising concerns about problematic use and its potential impact on health-related behaviours, including eating patterns. Intuitive eating, which emphasizes awareness of internal hunger and satiety cues rather than external influences, has gained attention as a positive approach to eating behaviour and overall well-being.

Objectives: The aim of this cross-sectional study is to assess smartphone addiction risk and intuitive eating behaviours among medical students and to investigate their association with sociodemographic characteristics.

Methods: 524 participants from Istanbul University - Cerrahpaşa Faculty of Medicine 1st, 2nd and 3rd year students were included in our study. Sociodemographic Data Form, Intuitive Eating Scale - 2 and Smartphone Addiction Scale - Short Form scales were applied to the participants face-to-face.

Results: Among all participants, 51,7% were found to be at risk of smartphone addiction. There was a negative correlation between Smartphone Addiction Scale score and Intuitive Eating Scale score. Participants with a chronic disease had a significantly higher risk of having smartphone addiction.

Discussion: In the present study, smartphone addiction was negatively correlated with intuitive eating behaviours, indicating that higher levels of problematic smartphone use are associated with lower intuitive eating scores among medical students. This finding is consistent with previous research demonstrating similar patterns in related contexts, suggesting that behavioural addictions can interfere with adaptive eating attitudes and behaviours.

Conclusion: In conclusion, this study highlights a significant negative association between smartphone addiction and intuitive eating behaviours among medical students, emphasizing the potential impact of problematic smartphone use on healthy eating practices.

ID 988- Chronic Diarrhea as a Paraneoplastic Manifestation of Papillary Renal Cell Carcinoma in a Patient with Type 1 Diabetes

Aleksandra JESIC, Ana PUDAR PURIC

Health Center Dz New Belgrade, Belgrade, Serbie

Context: • Smoking is classified as a modifiable risk factor that increases the risk of developing type 2 diabetes mellitus (T2DM). • Pathophysiological mechanisms by which components of tobacco smoke cause glucose intolerance and worsen clinical outcomes in patients with T2DM include: increased insulin resistance, impaired β-cell function and insulin secretion, chronic low-grade inflammation, endothelial dysfunction, indirect interaction with other factors that worsen diabetes.

Methods: Control of risk factors in people with diabetes mellitus: blood pressure, glycemia,

lipid profile, smoking, physical activity, body weight control, dietary habits.

Originality: • Epidemiological studies on the association between cigarette smoking and the development of type 2 diabetes have shown, in a study of 50,000 Chinese individuals followed for 5.4 years, that participants who smoked ≥20 cigarettes per day had an increased hazard ratio for developing T2D of 1.25 (95% CI: 1.00–1.56), while men with a smoking history of ≥40 cigarettes had an increased risk of T2D of 1.28 (95% CI: 1.04–1.57).

Lessons learned and future implications: • In the European Prospective Investigation into Cancer (EPIC-Norfolk) study of 2,704 men and 3,385 women, smoking was shown to be associated with an increase in HbA1c. Smokers of both sexes showed similar changes in HbA1c values—[an increase of 0.12% per 20 pack-years].

Discussion: • Healthy diet, regular physical activity, smoking cessation, and regular blood glucose monitoring are the main recommendations for diabetes control. • If you are not a smoker, do not start smoking; if you are, the best choice is to quit.

Conclusion: • Is there an alternative for those who choose an unhealthy lifestyle despite negative health consequences?

ID 1990- Chronic Kidney Disease: a proposal for inteìgrated management between Primary Care and Hospital Nephrology

Perrain ALICE, Sarron PIERRE-YVES

Médecine Générale Et Psychiatrie 37, La Croix En Touraine, France

Context: In a dual context of dwindling resources in psychiatry and a significant increase in mental health disorders, our system was created by the 6 Professional Communities Territories of Health and the Territorial Hospital Group of our department in 2021, to strengthen the outpatient mental health service. - Psychiatric telexpertise for general practitioners (720 in 5 years) and multidisciplinary team meetings for primary care teams. - Cognitive Behavioral Therapy groups (depression, insomnia, burnout): 955 patients referred, 525 patients treated in 5 years. Clinical improvement comparable to individual therapy. - Development of a shared culture among all mental health stakeholders in a given area, across the health, social, and medico-social sectors : webinars, monthly newsletters.

Methods: Initially deployed in one department, our program has benefited from ongoing state funding since 2023, allowing for expansion to other regions. We are currently deploying in three departments within the region, as well as in other departments across the country. To facilitate this, a deployment guide has been written, outlining the precise implementation process. We propose videoconference meetings with teams from other regions. Quantitative and qualitative monitoring of the deployments in the various regions is planned, including data collection and regional and national meetings with stakeholders in the departmental programs.

Originality: Our pragmatic approach relies on efficient and readily accessible resources for general practitioners to improve the management of specialist resources. It was designed from the outset to be replicable and adaptable to local resources.

Lessons learned and future implications: The success of this implementation depends on rigorous coordination, strong local ties, and a shared commitment to strengthening the links between general practitioners and psychiatrists.

Discussion: Monitoring the indicators will allow us to quickly identify the necessary adjustments and guide future developments of the system to better meet the expectations of healthcare professionals and patients in the area.

Conclusion: Our system ensures earlier detection and more appropriate treatment of mental health disorders as a whole. Deploying it in other regions means choosing an innovative and pragmatic strategy, based on

concrete and successful experience, to achieve a lasting improvement in the mental health of our citizens.

Marina JOTIC IVANOVIC [(1)] , Charlotte MORRIS [(2)], Seyma Handan AKYON [(3)]

(1) Public Primary Health Care Center Doboj, Doboj, Bosnie-Herzégovine
(2) University Of Manchester, Manchester, Royaume-Uni
(3) Sinan Educational And Research Hospital, Ankara, Türkiye

Context: As Family Medicine continues to evolve in response to changing healthcare needs, early professional interaction and knowledge exchange platforms play a crucial role. European Young Family Doctors' Movement (EYFDM) preconference exchange programs offer young family doctors unique opportunities for cross-cultural learning and capacity building. The city of XXX has hosted such an initiative aimed at strengthening family medicine through collaboration, education, and community interaction.

Methods: The EYFDM XXX preconference exchange involved participants from multiple countries engaging in clinical observations, an interactive workshop, and community-based activities. Qualitative feedback was collected via structured questionnaire to assess participant experiences and perceived learning outcomes.

Originality: To present the outcomes and impact of the preconference exchange program held in XXX, highlighting its role in shaping future leaders in family medicine, enhancing intercultural competence, and fostering professional networks.

Lessons learned and future implications: Participants reported significant gains in clinical insight, especially in the context of primary care delivery in resource-variable settings. From a future perspective, such programs add the value of international collaboration in strengthening primary healthcare systems and preparing young family doctors for leadership roles. The XXX experience suggests that preconference exchanges can serve as catalysts for sustained professional partnerships, joint educational initiatives, and collaborative research projects and contributing to the long-term success of family medicine at both local and international levels.

Discussion: The exchange fostered mutual understanding of diverse healthcare systems and inspired collaborative project ideas.

Conclusion: The XXX preconference exchange demonstrated the potential of short-term immersive programs to positively influence professional development and contribute to the global vision of family medicine. Such initiatives are instrumental in shaping a well-connected, culturally competent, and patient-centered generation of family physicians.

ID 1158- Classical Phased Evolution of EGPA: Importance of Early Recognition in Primary Care

Zainab SUAD

St George's University London, London, Royaume-Uni

Context: Acne vulgaris is one of the most common chronic inflammatory conditions managed in primary care. In the UK, acne accounts for approximately 3 million GP consultations annually, predominantly among adolescents and younger adults. Global prevalence continues to rise, particularly in those aged 15–19 years. As most acne is managed in general practice, adherence to evidence-based guidance is essential to optimise outcomes and minimise unnecessary antibiotic exposure. NICE NG198 provides clear standards for topical therapy, antibiotic prescribing, follow-up, and referral, supporting antimicrobial stewardship in primary care.

Objectives: To assess adherence in a UK general practice to NICE NG198 guidance for acne vulgaris, focusing on first-line topical management, systemic antibiotic use, follow-up practices, and referral of severe or refractory disease.

Methods: A retrospective, single-centre audit was conducted between April 2024 and April 2025. Patients with a coded diagnosis of acne vulgaris were included if sufficient clinical data was available. Data collected included demographics, acne severity, treatment initiated, systemic antibiotic use, follow-up within 12 weeks, and referrals to dermatology. Performance was descriptively assessed against NICE standards.

Results: First-line management: Most patients were initiated on guideline-recommended topical therapy. Antibiotic prescribing: Systemic antibiotics were largely prescribed in line with guidance and were predominantly tetracycline-based; however, a small but clinically relevant proportion commenced oral antibiotics as first-line therapy. Follow-up: Most patients were reviewed within the recommended 8–12 weeks, though documentation was inconsistent. Referral: Nearly all patients with severe acne were appropriately referred to dermatology.

Discussion: This audit demonstrated strong overall adherence to NICE guidelines, particularly for topical first-line therapy and referral practices. However, even infrequent initiation of systemic antibiotics first-line has antimicrobial stewardship implications when scaled across the high volume of acne consultations. Inconsistent follow-up documentation may increase the risk of prolonged or unnecessary antibiotic exposure. Targeted interventions, including improved documentation templates and prescribing prompts, could strengthen guideline adherence.

Conclusion: With millions of acne consultations managed annually in UK general practice, small deviations from guideline-based care can have substantial population-level consequences. Clear communication and reinforcement of evidence-based acne management are essential to support antimicrobial stewardship, optimise patient outcomes, and strengthen the role of primary care in delivering high-quality dermatological care.

ID 1340- Cleared for Space? Medico-Legal Risk in Recreational Spaceflight

Subir GHOSH [1] , Abhishek.Ghosh2@Nhs.Net GHOSH [2]

(1) Nhs,u.k., Braintree, Essex, Royaume-Uni
(2) Nhs,u.k., London Deanery, Royaume-Uni

Context: This is the case of a male patient who had a road traffic accident at age 9 years. At age 14, he presented with idiopathic limb pain syndrome and lumbar spine pain. He was also having neck and knee pain. Clinical examination at that time revealed pain in the lumbar spine on lightly pressing head (sign) and limited Straight leg rise. Ten fibromyalgia points were tender, and he was generally hypermobile (Beighton's score 6). Lumboscaral spine x ray showed pars defect. MRI scan was requested and showed congenital absence of inferior vena cava (IVC). A further MRI lumbar spine was arranged due to persistent back pain. MRI showed other vascular abnormalities. In addition to absent IVC there was increased size of hemiazygos and paravertebral veins and prominent veins at neuro foramina. This was possibly causing compression of co-existing structures contributing to lower back pain.

Methods: Case study of a real patient, review of MRI and CT images. For atypical presentation, a literature search was done.

Originality: Case study of a practice patient.

Lessons learned and future implications: Congenital absence of inferior vena cava usually presents with deep vein thrombosis. The patient was treated with high dose of painkillers for back pain. In this case there was delay in correlating back pain with congenital absence of inferior vena cava.

Discussion: Congenital anomaly like total absence or atresia of inferior vena cava is a rare condition. The incidence of absence inferior vena cava is 0.2-0.6% in healthy individual. As the collateral circulation through azygous and portal vein maintains sufficient venous return so patients are often asymptomatic. The condition may predispose to venous stasis leading to varicose veins and deep vein thrombosis.

Conclusion: In this case the patient developed lower limb pain and back pain from an early age. He was found not to have DVT and his thrombophilia screen was negative. It is possible that his symptom of leg pain was due to increased demand on venous system and stasis and the back pain due to increased endoneurial pressure.

Context: Point-of-care ultrasound (POCUS) enhances diagnostic accuracy, patient safety, and clinical autonomy in family medicine and is increasingly regarded as an extension of the clinical examination. Its relevance is particularly high in rural and underserved settings, where access to diagnostic imaging and specialist support is limited. Despite growing interest across Europe, access to structured, competency-based POCUS training remains uneven. Rural family physicians often face limited educational opportunities, insufficient local training capacity, and a lack of harmonized training standards. This heterogeneity raises concerns regarding quality assurance and safe clinical implementation. A coordinated European approach, grounded in competency-based medical education, is therefore required to support the effective, scalable, and sustainable integration of POCUS into routine family medicine practice.

Objectives: By the end of this workshop, participants will be able to: Describe key elements of a standardized European competency framework for POCUS in family medicine, with specific relevance to rural practice. Identify and compare scalable trainer-of-trainees (ToT) models to expand POCUS training capacity across countries and rural regions. Discuss governance, collaboration, and quality assurance mechanisms necessary to establish and sustain a European POCUS ToT network.

Teaching method and workshop: This 75-minute interactive workshop employs a blended educational design informed by adult learning theory and competency-based training principles, as outlined in EFSUMB and Wonca Europe position papers. Short plenary inputs introduce a European pilot in

Expected outcomes: Participants will gain practical and transferable insights into the development and implementation of a European POCUS ToT network. Outcomes include enhanced understanding of competency-based curriculum design, collaborative capacity building across count

Conclusion: This workshop promotes a collaborative, competency-driven, and evidence-informed approach to POCUS education, contributing to capacity building and supporting high-quality, sustainable integration of POCUS in family medicine across Europe.

ID 190- Clinical Assessment of Schisandra chinensis Extract for Knee Discomfort: An Exploratory Double-Blind, Randomized, Placebo-Controlled Trial

Daniel SUAREZ, Ramón MUNERA, Mari Carmen PONCE, Alberto COLL, Leticia MOLERON, Jose Luis GEA, Daniel ESTAÑ, Javier URIOS, Irene URIOS, Ruben CABRERA

Hospital De Orihuela, Orihuela, Espagne

Context: Clinical simulation is a necessary technique for medical professionals to acquire skills. Until now, mannequins representing human anatomy have been used, but recently, the development of virtual reality has become another tool for the training of future doctors.

Objectives: The aim of this study is the validation by medical professionals of a virtual reality tool developed in collaboration between the University of Jaime I of Castellon and the Vega Baja Hospital of Orihuela. The tool was developed taking into account the recommendations of primary care and emergency physicians in our department regarding orotracheal intubation.

Methods: A randomized group of physicians was selected to test an orotracheal intubation tool using virtual reality. The selected group consisted of physicians with the relevant speciality and clinical experience. Surveys were administered before and after using the tool to asses their level of satisfaction.

Results: Primary care and emergency medicine physicians rated the virtual reality tool favorably. Emergency medicine physicians identified more elements or details that could be developed or improved than primary care physicians.

Discussion: The mannequins currently used for orotracheal intubation require a monitor to supervise each step of the intubation process, and also require all the necessary intubation equipment. Virtual reality provides all the elements for intubation and for learning how to perform it, without the need for a monitor to supervise the process.

Conclusion: Virtual reality and its role in simulation processes for acquiring technical skills will gradually become the norm. It saves time, allows for repeated practice, and reduces the need for teaching staff. Currently, haptic gloves are too expensive, but with technological advancements, their availability will become more accessible in a few years.

ID 647- Clinical Efficacy of Codeine in Arthritic Pain: A Systematic Review

Subir GHOSH

Nhs,u.k., Braintree,essex, Royaume-Uni

Context: A 54-year-old gentleman presented to the surgery with intermittent abdominal pain, changes in bowel habits and lower urinary tract symptoms recurring over the last few years. All necessary investigations were performed but the diagnosis was unclear. Later in the course he presented with abdominal pain and change in bowel habits. Because of his age and change in bowel habits, investigations were arranged including blood tests, stool for microscopy and culture, faecal calprotectin and a faecal immunochemical test (FIT) to rule out lower bowel pathology (i.e. inflammatory bowel disease or bowel cancer). Blood tests and stool culture were normal. The faecal calprotectin was high (310 micrograms/g) and positive FIT (106.9 micrograms/g). He was referred on suspected cancer care pathway and was reviewed in lower GI clinic. A colonoscopy was performed but was incomplete as the colonoscope could not be passed beyond the splenic flexure due to looping. A CT colonography at the time showed malrotation of the midgut. The stool test for faecal calprotectin and faecal immunochemical test

led to urgent referral which threw light on the diagnosis.

Methods: Original case study from presentation to GP, investigation like colonoscopy and subsequent CT colonogram.

Originality: Original case study from practice.

Lessons learned and future implications: Presentation in subacute malrotation may be atypical and difficult to diagnose. The case was discussed in practice clinical meeting for shared learning.

Discussion: Malrotation occurs in approximately 1 in 500 births and usually presents during childhood. In rare cases, such as the one presented here, the patient may live well into adulthood without the diagnosis being made. In these cases, the patient tends to have subacute presentation of symptoms. This patient had several gastro-intestinal investigations in the past but none of them resulted in the diagnosis. This is likely due to intermittent malrotation, with investigations done during periods where the rotation was normal.

Conclusion: This is an interesting and novel case where malrotation was found to be associated with possible inflammation and microvascular changes, resulting in raised faecal calprotectin and positive FIT test.

ID 1778- Clinical Ethics Support and Education for General Practice Project: A view from pilot countries and global stakeholder discussion

Taras GRIADIL

Uzhhorod National University, Uzhhorod, Ukraine

Context: Family physicians work under high workload, time constraints, limited consultation duration, and sometimes language barriers, alongside extensive documentation requirements. These factors may impair clinical reasoning, patient–physician communication, and adherence to evidence-based care. Artificial intelligence (AI) tools, including speech recognition and clinical decision support systems, are increasingly integrated into primary health care to support physicians without replacing their professional role.

Objectives: Rather than viewing AI as an autonomous diagnostic system, this experience highlights its role as a clinical assistant. AI reduces administrative burden and frees cognitive resources, enhancing clinical reflection and empathic patient interaction.

Methods: This practice-oriented reflective analysis describes the implementation of AI tools in daily family medicine practice. Audio recording of consultations enables automatic transcription, real-time translation, structured organization of complaints and medical history, and data entry into electronic records. AI also assists in generating a preliminary diagnostic plan, differential diagnosis, and guideline-based treatment and follow-up recommendations. Final clinical decisions remain the physician's responsibility.

Results: The use of AI optimized consultation time and reduced routine documentation, allowing physicians to reallocate resources toward clinical analysis and patient-centered communication, including empathic dialogue and shared decision-making. Improved information structuring and collaborative decision-making enhance patients' understanding of their condition and treatment adherence. AI did not replace the family physician but reinforced the human dimension of medicine—empathy, trust, and individualized care. Further implementation requires ethical oversight, data quality assurance, data protection, and continuous physician supervision.

Discussion: AI may become an effective support tool for family physicians by systematizing data, assisting diagnostic reasoning, and facilitating adherence to clinical guidelines. However, at present, the underlying algorithms used by different AI providers are not fully transparent. Therefore, it is essential to avoid excessive reliance on technology and to preserve physicians' professional autonomy, as AI does not replace clinical judgment.

Conclusion: AI should be viewed not as a replacement for the family physician, but as a clinical assistant. By optimizing time and human resources, AI creates conditions for deeper analysis of patient health and more empathic interactions, ultimately improving the quality of primary health care and patient adherence—primarily through the preservation of the humanistic values of primary care.

ID 916- Clinical monitoring workload and use of technology for General practitioners due to private usage for GLP1 analogue injections for obesity

Julien FAVIER [(1)] , Ludovic ABUAF [(2)]

(1) Somnidoc 526 Chemin De La Tuilerie 42300 Villerest, Villerest, France
(2) Psass / Sleep Learning Center 50 Faubourg Dorleans, 41200 Romorantin-Lanthenay, Villerest, France

Context: Respiratory polygraphy (RP) is widely used in primary care to investigate suspected obstructive sleep apnea (OSA), particularly when access to polysomnography (PSG) is limited. However, RP may underestimate disease severity by failing to detect non-desaturating obstructive events associated with cortical micro-arousals, leading to discordance between respiratory indices and clinical symptoms.

Objectives: To assess whether integrating non-cortical physiological indicators into RP interpretation improves detection of obstructive respiratory events associated with micro-arousals, and to evaluate agreement between enriched RP and PSG-derived respiratory indices in a primary care context.

Methods: We conducted a retrospective single-center observational study including seven adult ambulatory PSG recordings. Each recording underwent two independent analyses: standard PSG scoring according to American Academy of Sleep Medicine criteria, and an RP-based analysis simulating a primary care setting enriched with two additional obstructive event categories. EOSD type 1 corresponded to non-desaturating hypopnea-like events, and EOSD type 2 to respiratory effort–related events. A suspected micro-arousal was identified in RP when at least three non-cortical indicators were present (ventilatory recovery, airflow normalization, respiratory effort changes, pulse wave attenuation, heart rate acceleration). Event-level diagnostic performance was assessed using sensitivity and positive predictive value (PPV) with exact 95% confidence intervals. Index-level agreement was evaluated using intraclass correlation coefficients (ICC) and Bland–Altman analysis.

Results: Enriched RP identified 1,064 PSG-confirmed respiratory micro-arousals, with an overall PPV of 91.1% (95% CI 89.3–92.7) and a sensitivity of 91.5% (95% CI 89.8–93.0). EOSD type 2 showed the highest predictive performance (PPV 93.6%, 95% CI 91.5–95.3). Agreement between RP-derived and PSG-derived indices was excellent, with ICC values of 0.982 for EOSD 1 versus non-desaturating hypopneas and 0.987 for EOSD 2 versus respiratory effort–related micro-arousals. Bland–Altman analyses showed minimal bias and narrow limits of agreement.

Discussion: Integrating non-cortical indicators substantially improves RP interpretation by reducing under-detection of clinically relevant obstructive events and improving concordance with PSG.

Conclusion: Enriched respiratory polygraphy provides reliable and clinically meaningful estimates of obstructive respiratory event burden. This pragmatic approach supports more accurate OSA assessment in primary care, particularly in isolated settings where polysomnography is not accessible. MeSH : Sleep apnea syndromes; Primary health care; Polysomnography

ID 892- Clinical Nutrition Management for 50-Year-Old Female Undernourished with Giant Neurofibroma Right Lower Limb: A Biomedical and Psychosocial Multidisciplinary Approach

Aneta NITSCH OSUCH, Agata CIUBA, Marta KULPA

Medical University Of Warsaw, Warsaw, Pologne

Context: Breast cancer is the most frequently diagnosed cancer and the leading cause of cancer-related mortality among women worldwide. In 2022, there were 2,296,840 new cases (age-standardised rate (ASR) 46.8/100,000) and 666,103 deaths (ASR 12.7/100,000). This disease constitutes a significant global public health burden, affecting countries irrespective of their economic development status. In Poland, 21,079 new cases were reported in 2021, representing 24.2% of all malignant neoplasms diagnosed in women.

Objectives: There are limited studies on the Polish population that simultaneously analyze knowledge, attitudes, and psychological and behavioral components affecting women's participation in breast cancer prophylactic examinations using standardized questionnaires, such as MHLC, HBI, and Mini-COPE. This gap is further underscored by international literature, where existing research often relies on proprietary questionnaires or singular standardized tools, resulting in fragmented insights. The study aimed to identify the key determinants influencing the willingness of Polish women to participate in breast cancer prophylactic examinations.

Methods: The study surveyed 407 women aged 45 to 69 between 2021 and 2022 and reported using the STrengthening the Reporting of OBservational studies in Epidemiology (STROBE) checklist. The research tool included an author-delivered questionnaire, the Multidimensional Health Locus of Control (MHLC) scale, the Health Behavior Inventory (HBI), and the Mini-Coping Orientation to Problems Experienced (Mini-COPE) inventory.

Results: Women were more likely to participate in screening if they were older, married, had children, used oral contraception, had received education on breast cancer prevention, had higher average intensity in the Health Behavior Inventory and scored significantly higher on the author's scale, and demonstrated an external health locus of control. Additionally, women who reported attending prophylactic examinations were significantly more likely to express a need for emotional support.

Discussion: Understanding the complex interplay of psychological, behavioral, and social factors that influence women's participation in breast cancer screening is vital to improving preventive healthcare outcomes.

Conclusion: Further research is necessary to gain a deeper understanding of the factors that motivate women to engage in health-promoting behaviors and to develop targeted interventions. The findings suggest that women who are well-informed about breast cancer prevention and feel comfortable accessing preventive services are more likely to undergo regular screening.

ID 936- Clinical simulation in the management of suicidal crisis in a bipolar patient in primary care

Belén VAZQUEZ MARIN, Natalia ALMENDROS VILCHEZ

Sas, Marbella, Espagne

Context: In Spain, the incidence of HIV in adolescence is low, representing 11.5% of cases. We present the case of a 15-year-old teenager from Cuba, highlighting the aspects in which Primary Care is fundamental.

Methods: Introduction: In Spain, the incidence of HIV in adolescence is low, representing 11.5% of cases. We present the case of a 15-year-old teenager from Cuba, highlighting the various aspects in which Primary Care is fundamental. Case Clinic: 14-year-old teenager , with a primary infection of syphilis, who moved from Cuba to Marbella . He came to the Family Doctor consult to continue medical follow-up. In Cuba, he presented an inguinal lesion suspected of syphilis that was confirmed

with serology and treated with a single dose of benzatinic Penicillin G (2.4 million units im). After the window period of STIs , he did a new serology test: HSV-1, HSV-2, Syphilis and VIH. The tests showed a positive Ig M for HSV-2 , AC against HIV, and Ig G against syphilis. As a under-age , the results were communicated to his mother and later to him. He was referred to the Internal Medicine Infectious Group of the Costa del Sol Hospital, the reference University Hospital in the area, where he was treated with Antiretroviral Therapy (HAART)

Originality: This case is unusual, given that the incidence of HIV in Spain is low, and even more so, a case in adolescence

Lessons learned and future implications: In this clinical case, we can show why Primary Care is fundamental: Care for the immigrant patient; health education, specifically , STIs , including VIH prevention, sexual education, and mental health. Professionals as family doctors, nurses are responsible for carrying out these tasks.

Discussion: Health education activities include workshops (nutrition, stress management, first aid), talks (addiction prevention, sexual health, mental health,), and others such as seminars, support groups, focusing on promotion, prevention, and healthy lifestyles for teenagers with the program Forma Joven.

Conclusion: We must learn that STI prevention activities and social support must be thorough and constant to educate the population and prevent new infections as much as possible.

Yusuf ARMAN [(1)] , Ikbal Humay ARMAN [(2)]

(1) Umraniye Adem Yavuz Family Health Center, Istanbul, Türkiye
(2) Department Of Family Medicine, School Of Medicine, Istanbul Medipol University, Istanbul, Türkiye

Context: Family doctors (FDs) act as the safety net of the healthcare system. This report illustrates how an FD's advocacy, based on their in-depth knowledge of a patient's medical history, led to the diagnosis of a rare ankle fracture that had initially been missed by secondary care.

Methods: A 35-year-old man applied the ER following a football injury. Initial X-rays were negative and he was diagnosed with a sprain. However, persistent pain led him to his FD on day-2 and the orthopedic specialist on day-7. Repeat physical examinations on these occasions showed decreased range of motion with no additional recommendations. On day-10, he returned to the FD, reporting constant pain, which worsened with effort. Physical examination again revealed generalized oedema and diffuse tenderness, with significant pain when bearing weight. The patient with no history of chronic pain was unresponsive to treatment. Suspecting an occult pathology, the FD wrote a detailed referral letter explicitly urging advanced imaging. An MRI scan revealed an isolated posterior malleolus fracture, which led to appropriate immobilization and recovery.

Originality: Isolated posterior malleolus fractures are rare and difficult to detect. This case is unique because the diagnosis was not driven by technology, but by the FD's core competency of providing holistic care. This proves that getting to know the patient is an effective diagnostic tool.

Lessons learned and future implications: A change in a patient's behaviour, such as an uncharacteristic complaint from someone who usually remains calm, should lead to a change in management. The threshold for advanced imaging (CT/MRI) should be lowered when the clinical course worsened after one week. FDs must move beyond passive gatekeeping to active advocacy.

Discussion: The literature suggests that plain radiographs may miss up to 50% of posterior malleolus fractures. This case highlights the limitations of relying solely on negative X-rays in cases of high-energy trauma and demonstrates how longitudinal care acts as a safeguard against false reassurance from technology.

Conclusion: Family doctors play a critical role in reducing diagnostic errors. By combining longitudinal knowledge with clinical advocacy, family doctors can recognise abnormal patterns in clinical recovery and ensure timely intervention for conditions that are not detected by standard screening.

Ludmila RESUTIKOVA

Resutik S.r.o., Ssgp, Velky Krtis, Slovaquie

Context: Introduction Until 2009 general practitioners in Slovakia performed ECG examinations only occasionally, because this service was not covered beyond the capitation payment. When Slovak general practitioners were given the opportunity to perform ECG as a procedure covered by health insurance, interest in performing it increased and there was a need to train general practitioners in the evaluation of ECG recordings.

Methods: Since 2015, due to the great interest of general practitioners the interactive ECG workshops and seminars have been held annually at the Slovak Society of General Practice (SkSGP) conference under my coordination and under the expert guidance of cardiologist Assoc. Prof. Slavomira Filipova ,M.D., PhD. , FESC .

Originality: After years of presenting case reports from my rural general practice annually , my own interactive ECG workshop, which actively engages the audience in the discussion from start to finish, was created. A case report of Brugada syndrome is briefly presented in the form of the ePoster.

Lessons learned and future implications: Regular ECG workshops and presentations contribute to the education of general practitioners in the evaluation of ECG findings and motivate them to use this examination method in daily practice.

Discussion: Is the memorable imprint of directly presented information the same as the value of information presented through brainstorming and quizzes?

Conclusion: An emotional case report from practice which needs to be actively resolved leaves a more memorable imprint than directly presented information.

Context: In today's world, social media is one of the main arenas where health information spreads – often faster than evidence-based knowledge can keep up. Doctors can play a key role in providing trustworthy medical content, yet many hesitate to engage. In this workshop, we want to encourage healthcare professionals to find their voice online and share practical tools for impactful communication. In the interactive part of the workshop, participants will work in small groups to brainstorm and create their own social media posts.

Objectives: Explain how trust is formed in online health communication. Apply communication principles to the creation of health-related social media content. Engage collaboratively in brainstorming and developing social media posts in a supportive peer-learning environment.

Teaching method and workshop: The workshop combines interactive lecture, facilitated group discussion, small-group collaborative work, peer feedback and collective reflection. First half: - begins with a short interactive lecture introducing the international research project Trust a

Expected outcomes: Demonstrate a stronger understanding of trust-building mechanisms in digital health communication. Report increased

confidence to engage in online health communication as healthcare professionals. Feel more empowered to contribute actively to health misin

Conclusion: As health conversations increasingly unfold in digital spaces, the absence of credible medical voices creates room for oversimplification, polarization, and misinformation. This workshop positions healthcare professionals as necessary participants in shaping how health knowledge is understood, trusted, and shared online. By emphasizing experimentation over perfection, the session offers a practical starting point rather than a finished formula.

Context: Continuing professional development (CPD) is a core component of quality and safety in general practice, enabling general practitioners (GPs) to maintain clinical competence and respond to evolving healthcare systems. Across Europe, the integration of artificial intelligence (AI) into healthcare and CPD is advancing, yet remains limited, fragmented, and uneven between countries and medical specialties. This situation generates uncertainty regarding the educational value, ethical implications, and practical relevance of AI for lifelong learning in general practice. GPs express strong interest in CPD programmes that are clinically relevant, accessible, and adapted to their professional context. There is therefore a clear need for a structured, critical, and practice-oriented discussion on how AI can support impactful CPD in general practice.

Objectives: - Outline the current level of integration of artificial intelligence into continuing professional development for general practitioners across different European countries. - Recognize core ethical principles relevant to AI-supported education in general practice. - Apply a critical framework to assess the relevance and limitations of AI-based CPD tools. - Define at least one actionable strategy to improve AI literacy or responsible use of AI in CPD.

Teaching method and workshop: The workshop will combine brief evidence-informed inputs with interactive methods, including small-group work and facilitated plenary exchanges. Participants will share experiences from different European contexts, fostering peer learning and collective r

Expected outcomes: Participants will develop a clearer understanding of the AI-related CPD landscape in Europe, improve their ability to critically evaluate AI-supported educational tools, and identify transferable strategies to support equitable and ethically responsible C

Conclusion: This workshop addresses a timely challenge for European general practice by combining evidence, practical experience, and interactive learning. It aims to equip GPs with critical perspectives and actionable strategies to engage responsibly with artificial intelligence in continuing professional development.

ID 1136- Co-creation of proposals to improve prevention and treatment of anxiety and depression in Spain

Stephanie Nicole REYES

University Of The Philippines-Philippine General Hospital, Manila, Philippines

Context: Family physicians provide comprehensive, continuous care that involves prevention, chronic disease management, and end-of-life support. Family medicine practice integrates medical management with assessment of family dynamics and cultural values. By supporting patient autonomy and guiding families through complex decisions, family physicians address clinical and psychosocial needs.

Methods: The patient is a middle-aged woman with advanced spinal metastases and required coordination of care and symptom management. As her condition progressed, her daughter and sibling assumed primary caregiving and decision-making roles, resulting in significant shifts in family responsibilities. Family assessment tools were employed to understand family dynamics, address caregiver strain, and clarify goals of care. Strengths of this case included thorough family assessment and proactive caregiver guidance, while limitations included limited time to fully address complex family dynamics due to the terminal nature of the patient's disease.

Originality: By using a patient-centered, family-focused, and community-oriented matrix to explore the patient and family's dynamics, the physician was able to identify caregiver strain, family enmeshment and social needs. Not only was symptom management done but emotional and practical needs of the patient and her family members were addressed.

Lessons learned and future implications: Early assessment of family structure and dynamics strengthens the ability to manage illness transitions, reduce caregiver strain, and support resilience. Future practice could benefit from structured multidisciplinary approaches to coordinate care across specialties, while addressing family and social factors.

Discussion: Complex care decisions can be guided using a structured, family-centered approach that balances patient preferences with family capacities. Analyzing family dynamics and leveraging community and system resources can improve care planning and support.

Conclusion: Family medicine extends beyond individual patient care to encompass family-centered, holistic support.

Ilksen Yazgulu SENOL, Alperen KUCUKUYSAL, Villdan MEVSIM

Dokuz Eylul University, Faculty Of Medicine, Department Of Family Medicine, Izmir, Türkiye

Context: Chest pain is a common reason for emergency department visits, where the primary clinical priority is the exclusion of acute coronary syndrome. Although this approach is appropriate and lifesaving, non-cardiac causes—particularly dermatological and neurological conditions—may be overlooked during rapid, protocol-driven assessments. In contrast, primary care settings allow more comprehensive physical examination and diagnostic integration. This case illustrates how careful inspection in family medicine led to the correct diagnosis after repeated negative cardiac evaluations.

Methods: A 58-year-old woman presented repeatedly to the emergency department with left-sided thoracic pain radiating from the back toward the chest wall. Serial high-sensitivity troponin measurements and repeated electrocardiograms showed no evidence of acute coronary syndrome. Despite reassurance, her pain persisted. The patient subsequently consulted a family medicine clinic. After detailed history-taking, a full physical examination was performed, including complete inspection of the upper body after removal of clothing. A clustered vesicular rash on an erythematous base, approximately 5 cm in diameter, was observed on the left lateral thorax at the level of the seventh rib, extending toward the posterior axillary line. The distribution of pain corresponded to the same dermatome. Based on these findings, a diagnosis of herpes zoster was established, and antiviral treatment was initiated.

Originality: This case highlights the diagnostic value of simple inspection in patients presenting with chest and back pain. It demonstrates how non-cardiac causes may be missed when physical examination is incomplete, despite extensive cardiac investigations.

Lessons learned and future implications: Time pressure and task-focused workflows in emergency settings may limit thorough inspection, particularly of posterior body regions. In primary care, continuity and adequate consultation time enable complete examination and broader differential diagnosis. Emphasizing inspection in patients with unexplained chest or back pain may reduce unnecessary investigations and diagnostic delays.

Discussion: Patients with herpes zoster may present with back or chest pain, which can mimic cardiac pain. Posterior localization of lesions may hinder detection during rapid emergency assessments. This case illustrates the difference between emergency and primary care approaches.

Conclusion: Careful physical inspection remains a cornerstone of clinical diagnosis. A comprehensive primary care approach can reveal conditions overlooked in acute care settings, ensuring timely treatment and avoiding unnecessary diagnostic procedures.

Daniel SUAREZ, Mari Carmen PONCE, Alberto COLL, Javier URIOS, Irene URIOS, Daniel ESTAÑ, Belen RAYOS, Jose Ramón SORAVILLA, Ramón MUNERA, Jose Luis GEA

Medical Doctor, Orihuela Hospital, Espagne

Context: We present a case of a patient who has suffered a work disability as a result of persistent chronic pain in the cervical area radiating to the right arm.

Methods: We are treating a patient suffering from chronic shoulder pain that radiates down the right arm. The patient has experienced persistent, debilitating pain for the past 5 years. She has even undergone surgery for cervical disc herniations. Ultimately, the patient is not

physically fit to continue working in her usual job as a cashier in a supermarket.

Originality: In this case we can observe that there is a loss of quality of care for the patient, since for many years and in multiple consultations with different specialists, he has not been diagnosed with an obvious injury to the spinal nerve that innervates the right trapezius muscle.

Lessons learned and future implications: The lesson we learn is that we must conduct a thorough medical history and a good physical examination, which involves undressing the patient for observation. Multiple complementary tests were performed, with the associated costs, but a simple visual examination failed to reveal that the patient´s right shoulder was lower than the left, despite the abscence of scoliosis.

Discussion: Overcrowded waiting rooms are not a problem for doctors to solve. If doctors want to provide high quality care, they must dedicate the time each patient deserves, based on their condition or reason for consultation. Therefore, flexibility in patient care must be established. We cannot be subject to political decisions made eithout considering the quality of care.

Conclusion: The quality of medical care in Spain is declining due to the inaction of the ruling political class, whic is neglecting its duties. This has led to an exodus of doctors to other jobs, private practice, or other countries due to deteriorating working conditions.

ID 287- Combined Effects of Osteoporosis and Obesity on All-Cause and Cardiovascular Mortality: Evidence from a Nationally Representative Cohort

Boudour KOUKI

Emergency Department, Charles Nicolle Hospital, Tunis, Tunisie

Context: Chronic obstructive pulmonary disease (COPD) is a common chronic respiratory condition. Bronchiectasis frequently coexists with COPD and defines a distinct overlap syndrome associated with worse clinical outcomes.

Methods: Clinical, biological, radiological, and arterial blood gas data were retrospectively analyzed from hospital records to describe disease progression and outcomes.

Originality: This case illustrates the severe clinical course of COPD–bronchiectasis overlap syndrome and highlights its prognostic implications.

Lessons learned and future implications: Early identification of bronchiectasis in COPD patients, particularly in primary care, may allow preventive strategies to reduce severe exacerbations and infectious complications.

Discussion: A 50-year-old man with known COPD and radiologically documented bronchiectasis presented with acute dyspnea, purulent sputum, and respiratory failure. Non-invasive ventilation was initiated. Despite treatment, the patient deteriorated rapidly, requiring invasive mechanical ventilation. He developed septic shock of pulmonary origin with refractory hypotension and hyperlactatemia. Broad-spectrum antibiotics and vasopressor support were administered, but the outcome was unfavorable.This case highlights the severity of the COPD–bronchiectasis overlap syndrome and its poor prognosis. The coexistence of bronchiectasis may promote chronic bacterial colonization, persistent airway inflammation, and recurrent infectious exacerbations, leading to rapid clinical deterioration. In this overlap phenotype, acute exacerbations tend to be more severe, less responsive to standard therapies, and associated with higher rates of respiratory failure and septic complications. The presence of bronchiectasis in COPD patients is therefore not a simple radiological finding but a marker of disease severity. Systematic evaluation for bronchiectasis in patients with frequent exacerbations could allow earlier intervention and tailored therapeutic strategies.

Conclusion: COPD–bronchiectasis overlap represents a severe and under-recognized phenotype. Improved detection and targeted therapeutic strategies are needed to improve prognosis in this high-risk population.

(2) Coordinating Investigator & Pi, Paris Site Sleep Centre, Hôpital Bichat – Claude-Bernard (ap-Hp); Inserm U1141 Neurodiderot, 46 Rue Henri Huchard, 75018 Paris, France, Paris, France
(3) Mitral Sas – Apneal, 8 Rue Jean Antoine De Baïf, 75013 Paris, Paris, France

Context: Primary care must quickly identify patients with obstructive or central sleep apnoea and organise a secure, guideline-aligned referral pathway. A chest-worn, smartphone-based screening device (class IIa medical device) coupled with a fully digital prescriber web-platform returns validated AHI metrics (overall and by type), positional analysis, event timeline and signal-quality flags, together with integrated onboarding questionnaires. This 60-minute workshop trains GPs to prescribe the system, teach correct phone placement, interpret AHI reports, and prepare and send a complete, secure referral to a sleep physician.

Objectives: By the end of the workshop participants will be able to: Prescribe and use the prescriber web-platform. Teach patients correct phone placement and onboarding to ensure valid recordings. Interpret the device

outputs (overall AHI, obstructive vs central, positional data, quality flags) and triage urgency. Prepare and transmit a concise, secure referral pack to a sleep physician following regulatory and data-protection requirements.

Teaching method and workshop: Brief clinical framing, live platform demonstration, hands-on role-play (GP as prescriber, peer as patient), decision flowchart exercise and real-time preparation and sending of a referral. Session ends after confirmed transmission to the sleep physician.

Expected outcomes: GPs leave with a one-page protocol and flowchart, a referral template, and practical skills to run the screening workflow and safely refer patients.

Conclusion: By the end of this workshop, participants are able to screen suspected sleep apnoea efficiently in primary care, using a chest-worn, smartphone-based medical device and a secure digital platform. They can ensure valid recordings, interpret AHI-based results, triage urgency, and identify red flags, and send a complete, secure referral to a sleep specialist. This workflow strengthens the GP's gatekeeping role, reduces delays to diagnosis, and improves coordination between primary and specialist care.

Boudour KOUKI

Emergency Department Of Charles Nicolle Hospital, Tunis, Tunisie

Context: Cerebral venous thrombosis (CVT) is a rare cause of stroke that can lead to cerebral edema, intracranial hemorrhage, and severe neurological complications. Autonomic nervous system dysfunction following acute brain injury may trigger life-threatening cardiac arrhythmias.

Methods: This case report is based on retrospective analysis of clinical data, imaging studies, laboratory findings, electrocardiographic monitoring, and neurological investigations collected during hospitalization.

Originality: This case highlights the association between CVT, refractory status epilepticus, and malignant cardiac arrhythmias in the absence of primary cardiac pathology.

Lessons learned and future implications: Severe neurological conditions may disrupt cardiac rhythm regulation. Early recognition of atypical neurological presentations and close cardiac monitoring are essential, including in patients without known heart disease.

Discussion: A 54-year-old man was admitted after a fall following a generalized tonic–clonic seizure. He rapidly developed refractory status epilepticus requiring mechanical ventilation. During hospitalization, he experienced ventricular fibrillation successfully treated with defibrillation. Etiological investigations were initially inconclusive. Cerebral CT angiography later revealed thrombosis of the left sigmoid sinus extending to the ipsilateral internal jugular vein.This case illustrates the diagnostic and prognostic challenges of cerebral venous thrombosis presenting with refractory status epilepticus. CVT may initially mimic other neurological emergencies, leading to delayed diagnosis when early neuroimaging is inconclusive. The occurrence of malignant ventricular arrhythmia in this patient highlights the impact of severe neurological injury on autonomic nervous system regulation. Intense sympathetic activation during refractory seizures and cerebral edema may precipitate life-threatening cardiac rhythm disturbances, even in the absence of structural heart disease. This neurocardiac interaction remains under-recognized and may contribute to unexpected mortality.

Conclusion: CVT may present with refractory seizures and severe autonomic dysfunction leading to malignant arrhythmia. Continuous cardiac monitoring should be systematically considered in patients with severe neurological involvement.

ID 196- Comparative analysis of end-of-life medical costs across care settings: home hospice, hospice ward, and general ward

Adina-Ioana BICĂJANU

Harghita County Ambulance Service; Family Medicine Residency Programme, Umfst, Târgu Mureș, Roumanie

Context: Uneven access to primary care can widen health inequities and shift demand towards emergency medical services, particularly outside office hours and in rural areas. Quantifying these patterns can support equity-focused planning in family medicine. The study setting includes dispersed rural communities and a culturally and linguistically diverse population.

Objectives: To assess whether family medicine service availability is associated with ambulance service utilisation across administrative areas, focusing on out-of-hours demand and urban-rural differences, and to identify areas with persistently high out-of-hours demand.

Methods: This study uses linked routinely collected administrative data in an area-by-year framework over 13 years. Ambulance dispatch records (place of request and timestamp) are linked to health insurance indicators at area level, including total resident population, insured and uninsured counts, contracted family medicine practice points, and contextual vulnerability indicators (disability and social care-related counts, such as sickness disability pension, institutionalised persons and placement centres). Outcomes are annual ambulance request rates per 1,000 residents and out-of-hours request rates. Primary care capacity is measured as contracted family medicine practice points per 10,000 residents. Temporal trends and area-level differences are examined, and count regression models with population offsets adjust for vulnerability indicators, the proportion uninsured, and urban-rural classification.

Results: Administrative indicators confirm feasibility for rate estimation and show a decline in contracted family medicine practice points over time. Area-level utilisation metrics are derived from ambulance dispatch data and combined with administrative indicators. The analysis quantifies geographic and temporal variation in ambulance demand and estimates adjusted associations between primary care capacity and overall and out-of-hours ambulance utilisation.

Discussion: Linked administrative data can help distinguish structural access gaps from expected demand, and out-of-hours utilisation may act as a marker of unmet access to timely primary care.

Conclusion: This approach can identify inequities in access to primary care and prioritise areas for targeted workforce planning and access interventions in underserved communities.

Context: An intersectional approach highlights that adolescent females are at risk not solely due to their gender, but also due to the combination of gender, race, class, and territory. The overlapping of these factors increases exposure to lethal violence, particularly in peripheral neighborhoods controlled by criminal factions, where state protective presence is limited. Rather than analyzing inequality through race or class alone, this approach seeks to understand it through the interactions of multiple power categories that mutually reinforce each other.

Objectives: To understand the vulnerability of adolescent females to homicide from the perspective of virtual violence and intersectionality.

Methods: The study employed a qualitative research framework and was conducted in two peripheral neighborhoods with high social vulnerability. Adolescent females aged 15 to 18 were included. Participants were selected using a snowball sampling technique. Semi-structured interviews were conducted and analyzed using discourse analysis.

Results: Findings indicate that violence extends to social media platforms and messaging apps, which are used by criminal factions for control, monitoring, and intimidation. In this context, such threats as exercises of power over bodies, regulating territories' influence on social relationships. Participants' accounts revealed everyday experiences shaped by multiple forms of oppression, including physical, psychological, symbolic, and virtual violence.

Discussion: The narratives reflect the constant fear experienced by peripheral adolescent females and illustrate the complexity of vulnerabilities across various territories, genders, races, and age groups. From an intersectional perspective, these layers demonstrate that Black and Brown girls experience violence not in isolation but as part of a historical process of exclusion, marginalization, and racialized poverty.

Conclusion: The study points to the need for research that gives a voice to vulnerable populations from an intersectional perspective.

Context: Point of Care Ultrasound (POCUS) is expanding in primary care. In June 2023, WONCA Europe issued a position statement on POCUS, emphasizing its utility in diagnosing or ruling out medical emergencies, managing low-to-moderate complexity conditions, and monitoring acute and chronic diseases, regardless of hospital infrastructure. In many European countries, ultrasound is already integrated into initial training and daily practice in general medicine. WONCA Europe recommends tailored training during the General Practice residency, followed by continuous professional development. Several Residency General Practice Departments (RGPDs) are introducing POCUS teaching within their programs.

Objectives: By the end of this workshop, participants will be able to: Understand the context and importance of integrating POCUS into General Practice residency programs. Identify key elements for designing a POCUS teaching program. Develop a roadmap for implementing POCUS teaching in their own residency programs.

Teaching method and workshop: Teaching methods: The workshop will use active learning methods, combining individual and small-group work, plenary discussions, and short presentations by facilitators. Participants' expectations and prior knowledge will be explored. The facilitation

Expected outcomes: Participants will leave with a roadmap to implement POCUS teaching program in their residency curriculum.

Conclusion: This workshop will provide participants with practical tools and a collaborative framework to integrate POCUS teaching into General Practice residency programs, fostering the dissemination of this essential skill in primary care.

Xavier SÁNCHEZ, Pablo CARRERA, María Daniela CORTEZ, Andrés CRUZ, Isaac MERCHÁN, Ruth JIMBO-SOTOMAYOR, Berzabé TELLO

Community And Primary Care Research Group – Ecuador (cpcrg-E), Centro De Investigación Para La Salud En América Latina (ciseal), Pontificia Universidad Católica Del Ecuador (puce), Quito, Équateur

Context: Depression is highly prevalent among medical students and residents and poses a significant threat to well-being, learning, and the future quality of primary care. While traditional approaches emphasize risk factors and lifestyle behaviors, humanistic and holistic models of care highlight the importance of cognitive–emotional resources that enable individuals to cope with sustained stress. Positive Mental Attitude (PMA), reflecting optimism, emotional regulation, and constructive coping, may represent a key dimension of mental health promotion in medical training.

Objectives: To assess the association between health behaviors—particularly Positive Mental Attitude—and depressive symptoms among medical trainees, and to explore the relevance of these findings for holistic care, health promotion, and medical education.

Methods: A cross-sectional study was conducted in 2025 among 700 medical trainees (393 undergraduate students and 307 postgraduate residents) at a university in Ecuador. Depressive symptoms were assessed using the Patient Health Questionnaire-9 (PHQ-9), with scores ≥10 indicating clinically significant symptoms. Health behaviors were measured using the Health Behavior Inventory, encompassing Healthy Eating Habits, Preventive Behaviors, Health Practices, and Positive Mental Attitude. Multivariable logistic regression models examined associations between health behavior domains and depressive symptoms, adjusting for sociodemographic, academic, and clinical variables.

Results: Overall, 47.7% of participants screened positive for depressive symptoms. Higher overall health behavior scores were associated with lower odds of depression (OR per point = 0.94; 95% CI: 0.93–0.95; p <0.001). When all behavioral domains were analyzed simultaneously, only Positive Mental Attitude remained independently associated with lower odds of depression (OR = 0.79; 95% CI: 0.74–0.84; p < 0.001). Female gender, younger age, and the presence of chronic comorbidities were associated with higher odds of depressive symptoms.

Discussion: These findings suggest that cognitive–emotional orientations may play a more central role in mental health than traditional lifestyle behaviors alone. PMA appears to function as a key protective factor, aligning with holistic and humanistic perspectives that emphasize resilience and emotional well-being in healthcare professionals.

Conclusion: Cultivating Positive Mental Attitude may represent a feasible strategy to protect against depression in medical trainees. Integrating health-promoting, humanistic, and strengths-based approaches into medical education and primary care training could support trainee well-being and foster more resilient and holistic future practitioners.

(1) Izmir Dokuz Eylül Üniversitesi Medical School-Izmir (türkiye) - Izmir (Türkiye), Izmir, Türkiye
(2) Izmir Dokuz Eylül Üniversitesi Medical School-Izmir (türkiye), Izmir, Türkiye

Context: Language barriers substantially complicate clinical assessment in emergency settings, particularly when patients present with acute neurological symptoms. Limited communication may result in diagnostic uncertainty, unnecessary investigations, and delayed treatment. Migrant patients are especially vulnerable in this regard. This case illustrates how acute neurological findings in a non–Turkish-speaking patient initially suggested stroke but were ultimately attributable to hypoglycemia, emphasizing the importance of effective communication and accurate history-taking.

Methods: A 48-year-old Syrian woman who did not speak Turkish was brought to the emergency department by ambulance in

September 2023 with acute disorientation, impaired eye coordination, inability to follow simple commands, and speech disturbance. She had no known chronic disease and was not using regular medication. An acute cerebrovascular event was initially suspected. Neurological examination and monitoring were limited due to patient restlessness, and the language barrier significantly restricted direct history-taking. Collateral history was obtained from her 25-year-old son, who had limited proficiency in Turkish. He reported similar previous episodes that had initially been evaluated as suspected stroke but were later diagnosed as hypoglycemia, with rapid recovery following intravenous glucose administration. Capillary blood glucose was measured and found to be 48 mg/dL. Intravenous dextrose was administered, resulting in complete resolution of neurological symptoms within approximately 10 minutes. After brief observation, the patient was discharged and left the emergency department independently.

Originality: This case demonstrates how language barriers can obscure straightforward diagnoses and lead to hypoglycemia being misinterpreted as an acute neurological emergency. It also highlights Whipple's triad identified through collateral history rather than direct patient communication.

Lessons learned and future implications: Language barriers may significantly delay diagnosis and increase unnecessary investigations. Early use of interpreters or reliable family members should be prioritized. Bedside glucose testing must remain a first-line assessment in unexplained neurological presentations.

Discussion: Hypoglycemia can mimic acute stroke with focal neurological signs. In the absence of effective communication, reliance on basic bedside assessments and collateral history becomes crucial.

Conclusion: Effective communication and systematic bedside evaluation are essential for diagnostic accuracy. Addressing language barriers can prevent misdiagnosis, reduce unnecessary interventions, and ensure timely, appropriate treatment.

Elmira ASTANOVA

Nurlan Nurgazievich Brimkulov, Bishkek, Kirghizistan

Context: Depression is a frequent comorbidity in patients with type 2 diabetes mellitus (T2DM) and affects disease control, self-management and clinical outcomes. While depressive symptoms in T2DM are widely reported, less is known about differences in depression severity between urban and rural primary care settings, where access to healthcare resources and mental health services may differ substantially.

Objectives: To compare the severity of depressive symptoms and associated clinical characteristics among patients with T2DM receiving primary care in urban and rural settings, and to explore implications for early detection and management of depression in primary care.

Methods: To compare the severity of depressive symptoms and associated clinical characteristics among patients with T2DM receiving primary care in urban and rural settings, and to explore implications for early detection and management of depression in primary care.

Results: Among 380 patients included, depressive symptoms were identified in 57.7%. Mild depression predominated overall; however, marked urban–rural differences in severity were observed. Patients in rural primary care settings demonstrated a substantially higher proportion of moderate-to-severe and severe depression compared to urban patients, among whom mild forms were more common. Poor glycaemic control (HbA1c >7.5%) and diabetes-related complications were more frequent in the rural group and were strongly associated with higher

depression severity. All patients with poorly controlled diabetes exhibited depressive symptoms, with severe forms clustering predominantly in rural settings.

Discussion: Although overall prevalence was comparable, rural patients with T2DM experienced more severe depressive symptoms. These findings suggest delayed recognition of depression, limited access to mental health services, and a higher clinical and psychosocial burden in rural primary care settings

Conclusion: Patients with T2DM in rural primary care are at increased risk of moderate-to-severe depression compared to urban populations. Integrating routine depression screening into diabetes care, strengthening mental health competencies of primary care physicians, and prioritising rural settings may reduce inequities, improve outcomes, and support patient-centred chronic disease management.

Context: Long working hours in health professionals have been linked to sleep deprivation, dietary changes and burnout, with potential variation by sex and migration-related background. Evidence from large professional samples in Spain describing these patterns by sex and birthplace is limited.

Objectives: To assess the association between long working hours (>40 hours/week) and sociodemographic and health-related behaviours, exploring patterns by sex and birthplace (born in Spain vs outside Spain).

Methods: Cross-sectional survey (2021) administered to professionals affiliated with the Medical Association of the Province of Barcelona. Data included sociodemographics (sex, age group, birthplace), health behaviours (physical activity; sleep duration <6 vs ≥6 hours; appetite changes; diet), burnout and substance use. We estimated the prevalence of long working hours and compared proportions by sex and birthplace using chi-square tests. We fitted binary logistic regression models to identify asociations with long working hours, including analyses stratified by sex and birthplace.

Results: Among 2,261 respondents, 38.5% reported working >40 hours/week. Long working hours were more common in men than women (43.2% vs 37.1%; p=0.0139) and did not differ by birthplace (40.0% born outside Spain vs 38.4% born in Spain; p=0.6739). Moderate-to-severe client-related burnout was higher among those born outside Spain (28.9% vs 19.5%; p=0.00094). In regression models, long working hours were associated with sleeping <6 hours, reporting a less healthy diet than usual and higher coffee consumption; older age showed a protective association. Some associations differed in magnitude across sex and birthplace strata.

Discussion: In this sample, long working hours affected over one third and were more prevalent among men. The co-occurrence of long working weeks with sleep and dietary disruption supports plausible pathways linking workload to health risk. Higher burnout among respondents born outside Spain highlights potential structural vulnerabilities warranting focused analyses.

Conclusion: Long working hours were frequent among Barcelona health professionals and were linked to potentially modifiable behaviours, particularly sleep and diet. Occupational-health strategies addressing work-time demands should integrate sex- and birthplace-sensitive approaches.

Hayley Ling HONG, Lai Peng NG

Singhealth Polyclinics, Singapore, Singapour

Context: The liver plays a central role in cholesterol metabolism. Several studies report an inverse association between low-density lipoprotein cholesterol (LDL-C) and total cholesterol levels with the risk of hepatocellular carcinoma, and reduced LDL-C may reflect underlying liver pathology. Conversely, hypercholesterolaemia is rarely observed in hepatic malignancy, except in uncommon subtypes such as clear cell hepatocellular carcinoma.

Methods: We report a 58-year-old man with metastatic rectal adenocarcinoma and extensive hepatic involvement who presented with a marked and unexpected rise in LDL-C. During routine follow-up for hyperlipidaemia, his LDL-C increased from 3.23 mmol/L to 8.64 mmol/L over one year. Following complaints of intermittent abdominal bloating and hepatomegaly on physical examination, imaging revealed multiple hypo-enhancing hepatic masses suspicious for hepatic metastases. Alternative secondary causes of hypercholesterolaemia, including hypothyroidism, nephrotic syndrome, and chronic kidney disease, were considered and excluded.

Originality: While advanced liver disease and malignancy typically reduce cholesterol levels due to impaired hepatic lipid metabolism, hypercholesterolaemia can occur in cholestatic states through accumulation of lipoprotein X (LpX), an abnormal phospholipid-rich, apolipoprotein B (ApoB)-negative lipoprotein. Standard lipid assays may not distinguish LDL from LpX without specialised techniques. In this case, the reported LDL-C, calculated using the Friedewald equation, may be inaccurate if there is significant LpX accumulation, as total cholesterol measurements include LpX.

Lessons learned and future implications: Abrupt or unexpected increases in LDL-C may indicate underlying hepatic pathology, particularly cholestasis. When falsely elevated LDL-C is suspected, additional testing can be considered. ApoB measurement may help to differentiate true LDL-C elevation from LpX-related pseudo-hypercholesterolaemia, as LpX lacks ApoB. A normal ApoB level despite markedly elevated LDL-C strongly supports this diagnosis. Lipid electrophoresis can confirm the presence of LpX, though it may not be routinely available.

Discussion: Our patient's liver biochemistry demonstrated a cholestatic pattern with elevated alkaline phosphatase (194 U/L) and gamma-glutamyl transferase (334 U/L). We suspect that the abrupt rise in calculated LDL-C reflects LpX accumulation rather than a true increase in LDL-C.

Conclusion: There is a growing number of case reports highlighting LpX as a cause of pseudo-hypercholesterolaemia. Recognition of atypical lipid profiles should prompt consideration of secondary causes, and appropriate confirmatory testing can support timely evaluation and accurate diagnosis.

ID 980- Congestive heard failure assessed by inferior vena cava ultrasonography in primary care. Cross-sectional study

Dahlia LESHNO

Tel-Aviv University, Tel-Aviv, Israël

Context: Attention deficit hyperactivity disorder (ADHD) is characterized by symptoms such as inattention, hyperactivity, and impulsivity, with a significant impact on a person's overall health and well-being. The impact of ADHD on healthcare costs is limited.

Objectives: The aim of this study is to examine the extent to which a diagnosis of ADHD affects health expenditure.

Methods: The study group contained all Maccabi HMO patients aged 18 and over who have a diagnosis of ADHD. The control group

included patients aged 18 and over without ADHD in a ratio of 1:3 matched by propensity score . We compared ADHD vs non-ADHD medical costs for each calendar year between 2018–2023. Group comparisons of medians are reported using the non-parametric Mann–Whitney U test in unadjusted analyses. Annual healthcare costs were analysed using a generalized linear model with a Tweedie distribution and a log link function, appropriate for right-skewed cost data with non-negative values.

Results: The study included 32,159 individuals diagnosed with ADHD and 96,632 non-ADHD controls. Between 2018 and 2023, individuals with ADHD demonstrated persistently higher annual healthcare costs compared with non-ADHD controls, with significant differences observed across all calendar years and cost categories. Category-specific analyses showed that physicians cost as well as hospitalization cost, contributed most to this difference, while medications cost showed smaller but increasing differences over time. Generalized linear model showed that male gender was associated with lower expected costs compared with females; smokers had 20% higher expected costs than non-smokers and age was positively associated with cost. Socioeconomic status was inversely related to cost.

Discussion: For our research we used a relevant data rich source. Nevertheless, other factors like ADHD heterogenicity, treatment complexity, and nonmedical treatment can affect the results. ADHD profiles and treatment adherence pattern can also affect cost data.

Conclusion: Our finding show that healthcare costs of patients diagnosed with ADHD is higher than patients not diagnosed with ADHD in many categories of healthcare costs. There is more research needed to identify what are the main cost amplifiers.

ID 1417- Congestive heard failure assessed by inferior vena cava ultrasonography in primary care. cross-sectional study.

Felipe SANTOS, Fernanda CROCE, Lorrayne LISBOA, Clesio VENANCIO, Fernanda DILLY, Marcella SEIBERT

Icepi, Vila Velha, Brésil

Context: Healthcare professionals in the Brazilian Unified Health System (SUS) face high levels of stress, anxiety, and musculoskeletal pain due to demanding environments, leading to significant absenteeism. This project was developed at the São Cristóvão Basic Health Unit in Vitória, Brazil, to address the wellbeing of the unit's own workforce through Integrative and Complementary Practices (PICS)

Methods: The intervention targeted the "caregiver" rather than the patient. The process included: 1) Initial diagnosis using validated Visual Analog Scales for stress and pain; 2) A structured protocol conducted by a physician and a pharmacist in a private setting; 3) Systematic sessions of auriculopressure targeting neurophysiological points for pain and anxiety; and 4) Pre- and post-intervention monitoring to measure impact on health status and potential reduction in sick leave.

Originality: While Auriculotherapy is a common PICS offered to the community, this project is innovative by institutionalizing it as a clinical occupational health intervention within the primary care setting. It treats worker health not just as an administrative requirement, but as a clinical priority, promoting a healthier environment from the inside out

Lessons learned and future implications: The implementation highlighted that health professionals frequently neglect their own self-care. Auriculotherapy proved to be a low-cost, non-invasive, and highly accepted technology. The intervention effectively reduced acute symptoms of anxiety and pain, which are primary drivers of professional burnout. Future implications include the institutionalization of "Self-Care Intervals" for staff to improve workforce retention and mental health resilience.

Discussion: The project demonstrated that integrating complementary therapies into the workplace increases team cohesion and individual productivity. It challenges the "absenteeism-illness" cycle by providing practical tools for emotional and physical management within the work routine.

Conclusion: This practice reinforces the "National Humanization Policy" by valuing workers. A healthy team is essential for high-quality community care. Auriculotherapy is a viable, holistic, and effective strategy to strengthen the primary care workforce.

Corresponding author: Felipe Santos, felipexim@gmail.com

ID 1314- Continuing education for interprofessional teams in primary health care to improve the quality of care in hypertension and type 2 diabetes mellitus

Mélanie BADIN, Pierre-Marie BADIN, David JUGE, Chloé SIKIRDJI

Faculté De Médecine De Montpellier-Nîmes, Montpellier, France

Context: Access to primary care in the Gard Department, as in much of France, has deteriorated, causing delayed consultations and high use of emergency departments (ED). Many patients postpone care due to long waits, while avoidable emergency visits remain frequent. Rising demand for unscheduled care (USC) has led to non-coordinated USC centres, which provide unplanned care but may disrupt primary care by diverting clinicians from longitudinal care. To address these challenges, three Coordinated Center for Unscheduled Care same-day care (CC-USC) structures were established to expand access without extending physician hours, reduce inequalities, and integrate USC into primary care.

Methods: CC-USCs are located in Pont-Saint-Esprit, Bessèges, and Vergèze, staffed by stable multidisciplinary teams of general practitioners, nurses, and medical assistants. Each morning, a three-person team provides walk-in access using two to three consultation rooms. Patients are triaged by a medical assistants and seen if they belong to the primary care team or live in the territory without a family doctor. Others are asked to call the on-duty Gard regulatory physician and are redirected to CC-USC if needed. Only unscheduled care is addressed; routine or administrative requests are excluded. Nurses manage prioritisation, initiate consultations, and handle simple cases using validated protocols, while physicians manage most consultations. Strengths include structured triage, continuity within primary care, and population-based care. Limitations involve constrained infrastructure, practice-funded staffing, and limited nurse autonomy.

Originality: Unlike non-coordinated USC centres, CC-USCs are integrated within primary care teams, and adopt a population-based approach to unscheduled care. No comparable structures currently exist in France.

Lessons learned and future implications: Future evaluations will assess whether CC-USCs increase access, reduce physician time spent on unscheduled care, and decrease ED use. The model could be scaled to other multidisciplinary practices, preventing the disorganisation caused by non-coordinated USC centres.

Discussion: International evidence suggests that coordinated same-day care models improve continuity and reduce avoidable emergency visits, supporting the innovation of CC-USCs. While limitations remain, the model offers a replicable framework in other places in France.

Conclusion: CC-USCs represent a scalable innovation to strengthen community-based primary care, improve access and quality of unscheduled care, reduce ED use, and provide a blueprint for broader implementation in primary care settings.

ID 1027- Continuing education strategy for primary health care physicians on the pharmacological management of people living with chronic conditions

Yiu-Hua CHENG [(1)], Hsin-Yu CHEN [(1)], Yi-Wen TSAI [(2)]

(1) Department Of Family Medicine, Chang Gung Memorial Hospital Keelung, Keelung, Taïwan
(2) Department Of Family Medicine, Chang Gung Memorial Hospital Linkou, Taoyuan City, Taïwan

Context: Chronic liver disease (CLD) is highly prevalent in XXX and commonly managed in primary care and shared-care settings. Esophageal variceal bleeding (EVB) is a severe and potentially fatal complication of advanced CLD that often presents unpredictably and substantially affects quality of life and end-of-life care. For family physicians, early identification of patients at high risk of EVB is essential to enable timely referral, preventive interventions, and informed discussions with patients and families.

Objectives: This study aimed to develop an interpretable machine learning model to support EVB risk stratification in non-cancer CLD patients within routine clinical practice.

Methods: We conducted a retrospective cohort study using data from the XXX Medical Research Database between 2010 and 2017. Patients with liver cancer, uncomplicated CLD, or incomplete data were excluded. Several machine learning models were developed to predict EVB risk in non-cancer CLD patients, and their predictive performances were compared. Model interpretability was assessed using SHapley Additive exPlanations (SHAP) to enhance clinical applicability in primary care settings.

Results: A total of 4,080 patients were included, of whom 1,004 experienced EVB. Among the evaluated models, the extreme gradient boosting (XGBoost) model achieved the best predictive performance. The most influential predictors were clinical parameters, including C-reactive protein, hemoglobin, platelet count, and serum albumin.

Discussion: An interpretable XGBoost-based model using commonly available laboratory data can effectively stratify EVB risk in non-cancer CLD patients.

Conclusion: This approach has potential value in primary care to support early risk recognition, guide referral decisions, and facilitate shared decision-making regarding prevention, monitoring, and palliative care planning.

(2) T.c. Saglik Bakanligi Kutahya Altintas 6 Nolu Aile Hekimliği, Kutahya, Türkiye

Context: Dysmenorrhea is a common reason for consultation in primary care among women of reproductive age. This case highlights the importance of combining history-taking and physical examination to detect an underlying surgical pathology in pain perceived as “habitual” by the patient.

Methods: A 25-year-old woman presented to a family medicine clinic with a complaint of dysmenorrhea. She reported regular menstrual cycles, typically associated with pain during the first two days. In the current cycle, menstruation had started on the expected date, and the patient was on the second day of bleeding at the time of presentation. She stated that she usually experienced relief with NSAID analgesics; however, she had taken her last available dose the previous evening and attended the clinic to request a prescription. It was clarified that she was virginal and that there was no suspicion of pregnancy. The patient described the current pain as similar in character to the pain experienced during previous menstrual periods. Physical examination revealed tenderness in the right lower quadrant and suprapubic area, with rebound tenderness and mild guarding of unclear voluntary origin. Based on these findings, the patient was referred to the emergency department with a preliminary diagnosis of acute appendicitis. Follow-up revealed that the patient underwent surgery with a confirmed diagnosis of acute appendicitis and benefited from timely diagnosis and treatment due to early referral.

Originality: This case highlights that patients may, without malicious intent, present their symptoms within a familiar framework to facilitate fulfillment of their perceived needs, which can mislead clinical evaluation. It also demonstrates how physical examination findings can fundamentally alter clinical decision-making.

Lessons learned and future implications: Patient narratives and clinical findings must always be assessed together and critically. Exclusive reliance on a "familiar pain" description could have resulted in a missed diagnosis of acute appendicitis.

Discussion: This case emphasizes the risk of prematurely concluding diagnostic assessment in primary care when patients associate their symptoms with previously experienced benign conditions.

Conclusion: Physical examination is an indispensable component of the art of medicine. Holistic clinical assessment is essential for timely identification of serious conditions.

Aiste ZIAUGAITE, Gintare SIAUDIKYTE, Kipras BALCIUNAS

Lsmu Lithuanian University Of Health Sciences, Kaunas, Lituanie

Context: Urinary tract infections (UTIs) are among the most common bacterial infections in pediatric patients and a frequent reason for primary care consultation. While isolated episodes are usually managed empirically, recurrent UTIs may indicate underlying anatomical or functional disturbances. Functional bowel–bladder dysfunction, particularly constipation, is increasingly recognized as a reversible risk factor, especially in female pediatric patients. Early recognition in primary care is essential to prevent recurrence and reduce unnecessary antibiotic exposure.

Methods: A 7-year-old female pediatric patient presented after a third UTI episode within eight months. Symptoms included dysuria, urinary frequency, and low-grade fever. Previous episodes had been treated empirically without microbiological confirmation or imaging. Urinalysis showed leukocyturia, and urine culture grew Escherichia coli sensitive to first-line antibiotics. History-taking revealed chronic constipation. Renal and bladder ultrasonography showed no structural abnormalities but incomplete bladder emptying, consistent with functional bowel–bladder dysfunction. Management included culture-guided antibiotics, a bowel regimen, and counseling on hydration, regular voiding, and toileting. No further UTIs occurred during six months of follow-up.

Originality: This case highlights constipation as a modifiable functional contributor to recurrent UTIs identified in primary care. Unlike reports focused on anatomical anomalies or specialist-led evaluations, it demonstrates how comprehensive history-taking and non-invasive assessment can guide effective management.

Lessons learned and future implications: Constipation may increase bladder pressure, impair emptying, and promote urinary stasis, facilitating infection. Assessing bowel habits in children with recurrent UTIs may reduce recurrence and support antibiotic stewardship. Integrating bowel–bladder evaluation into primary care can improve long-term outcomes.

Discussion: Functional bowel–bladder dysfunction is a well-documented but often underrecognized contributor to recurrent UTIs. Fecal retention can mechanically and functionally interfere with bladder emptying, increasing post-void residual urine and infection risk. Studies demonstrate a significant association between constipation and recurrent UTIs, with improvement after bowel management. Pediatric guidelines emphasize assessing bowel habits as part of the evaluation for recurrent UTIs, particularly in female patients.

Conclusion: Recurrent UTIs in pediatric patients warrant further diagnostic evaluation in primary care. Early recognition and

management of constipation and bowel–bladder dysfunction can prevent recurrence, limit unnecessary antibiotic use, and enhance quality of care.

ID 26- Convergence des entrepôts de données de santé issus des soins primaires et de l'hôpital : perceptions professionnelles – une étude qualitative exploratoire

Jefferson GUMIRAN

Cauaya District Hospital, City Of Cauayan, Philippines

Context: Rheumatic Heart Disease (RHD) remains a significant yet underrecognized cause of cardioembolic stroke in low- and middle-income countries. Subtle neurological symptoms such as dysarthria may represent early warning signs of acute ischemic stroke, particularly in patients with longstanding valvular disease and atrial fibrillation. Early recognition is crucial, especially in primary-level hospitals where diagnostic and specialist resources are limited.

Methods: This report describes a 38-year-old Filipino male with a long-standing history of RHD and poor treatment adherence who presented to a primary-level district hospital with acute-onset dysarthria and right-sided weakness. Clinical evaluation, focused neurological examination, laboratory tests, electrocardiography, and delayed neuroimaging and echocardiography were utilized to establish a working diagnosis of acute ischemic stroke, likely cardioembolic in origin. Management was guided by national stroke guidelines and resource availability, emphasizing stabilization, anticoagulation, neuroprotection, and coordinated referral.

Originality: This case highlights dysarthria as the primary presenting symptom of stroke in an RHD patient managed in a resource-limited primary hospital. It underscores the continued burden of RHD-related stroke and illustrates real-world challenges in diagnosis and management where advanced imaging and subspecialty care are not immediately accessible.

Lessons learned and future implications: The case reinforces the importance of maintaining high clinical suspicion for stroke in high-risk cardiac patients presenting with isolated speech disturbances. It emphasizes the value of thorough history-taking and neurological examination in guiding timely management. Strengthening community-based RHD and stroke screening, improving health literacy, and enhancing referral systems are essential to reduce preventable morbidity.

Discussion: RHD-associated valvular pathology and atrial fibrillation substantially increase the risk of cardioembolic stroke. In this patient, delayed follow-up and nonadherence contributed to recurrent cerebrovascular events. Despite infrastructural constraints, early clinical recognition and adherence to basic stroke protocols facilitated stabilization and recovery. This case reflects the realities faced by primary hospitals in developing regions and highlights the need for system-level improvements.

Conclusion: Dysarthria may serve as an early harbinger of stroke in patients with Rheumatic Heart Disease. Prompt clinical recognition, even in the absence of advanced diagnostics, can lead to timely intervention and favorable outcomes. Strengthening primary care capacity and preventive strategies is critical in reducing RHD-related stroke burden.

(2) Meuhedet Health Services, Tel Aviv, Israël

Context: Individuals who have suffered a cardiovascular event face an elevated risk of experiencing another such event. Secondary

prevention strategies also involve medications aimed at reducing low-density lipoprotein cholesterol (LDL-C) levels, which play a key role in cardiovascular disease management. However, despite therapy, a significant portion of patients do not achieve the LDL-C targets recommended by guidelines and may need further interventions. To enhance hyperlipidemia treatment for its members, clinical pharmacists provided targeted consultations to primary care physicians (PCPs). These consultations focused on patients who had a history of cardiovascular events and remained above the LDL-C goal of 55 mg/dL despite receiving high-intensity statin therapy.

Objectives: This study evaluated the relationship between clinical pharmacist consultations and improvements in LDL-C control. The program received support from Novartis Israel Ltd.

Methods: From March 2023 to May 2025, an observational cohort study was conducted using data from a large HMOs electronic medical record, including patients whose PCPs received consultations. The main objective was to determine the proportion of patients who did and did not apply their given recommendation, that reached target LDL-C levels over time. T-tests were conducted to evaluate change in LDL-C levels at 6 month time points compared to the baseline measurement.

Results: Consultations were given to PCPs of 1289 patients, 78% males with a median age of 67 (IQR 60-74), 626 (49%) of who applied their given recommendation. The proportion of patients who achieved target levels increased over time with higher proportions observed among the applied sub-group of patients. LDL-C levels were statistically significantly reduced from baseline to follow-up periods among the applied population with average percentage decrease of 20-26%.

Discussion: These findings suggest that targeted clinical pharmacist consultations may assist in LDL-C reduction among high-risk patients who remain above guideline-recommended targets. Patients whose physicians applied the recommendations demonstrated greater improvements, highlighting the value of pharmacist–physician collaboration in secondary prevention. Future research should explore long-term cardiovascular outcomes and identify barriers to implementing recommendations.

Conclusion: LDL-C levels continuously reduced following clinical pharmacists' consultations regarding treatment among patients who had not reached recommended levels of LDL-C, with higher reductions observed among patients who applied the recommendation more broadly.

Context: Restless Legs Syndrome (RLS) is a common neurological condition impairing sleep and quality of life. In primary care, prevalence estimates often rely on standardized questionnaires, yet less is known about symptom identification during routine consultations without systematic screening.

Objectives: To assess the frequency of spontaneously reported restless legs symptoms during routine health check-ups in a primary care setting, and to explore associated demographic, sleep-related, biological and clinical factors.

Methods: We conducted a retrospective observational study based on 239,876 adult health check-ups performed between 2004 and 2022 in a French primary care prevention centre. Restless legs symptoms were identified solely through spontaneous patient complaints recorded during the clinical interview and coded as present or absent. Analyses were stratified by age and sex. Associations were examined with poor sleep complaints, Epworth

Sleepiness Scale (ESS; categories <7, 7–13, ≥14), haemoglobin level and cervical pain. A multivariable logistic regression model included sex, age, poor sleep, haemoglobin, cervical pain and ESS category.

Results: Out of 239,876 exams, only 581 patients reported symptoms (frequency: 0.24%). The "typical" case was a woman (68% of cases, ratio 2.1:1) between 35 and 65 years old. Key findings: Risk factors: Female sex (OR=3.0), aging (OR=2.0), and poor sleep (OR=1.6). The "Spine" connection: We found a clear cranio-caudal gradient. The risk was high for cervical pain (OR=2.1) but disappeared for low back pain (OR=1.3, NS). Sleepiness: Higher ESS scores were directly linked to more complaints.

Discussion: The observed frequency (0.24%) is markedly lower than the 2–10% usually reported in the literature, indicating substantial under-recognition of RLS in routine primary care when relying solely on spontaneous symptom reporting. Despite this, associated factors align with known clinical characteristics of RLS. Improved recognition is clinically relevant, particularly in light of emerging evidence suggesting a possible association between RLS and increased cardiovascular risk.

Conclusion: Restless legs symptoms are rarely identified during routine primary care assessments based on spontaneous complaints alone. Simple and systematic screening in patients presenting with sleep complaints or chronic pain may improve earlier recognition of RLS and facilitate appropriate management of associated comorbidities.

Context: Healthier XX is a national primary care reform introduced in 2023 to strengthen preventive care through patient enrolment, continuity, and personalised care with a regular primary care provider. Evidence on its early impact on preventive service uptake remains limited.

Objectives: To evaluate whether enrolment in Healthier XX is associated with changes in preventive care uptake following COVID-19–related disruptions.

Methods: We conducted a retrospective cohort study using routinely collected electronic medical records from a major public primary care clinics cluster. The study included 395,156 patients aged 40 years and above with longitudinal engagement between January 2018 and September 2024. Preventive services examined were cervical cancer screening, cardiovascular risk screening, influenza vaccination, and pneumococcal vaccination. Quarterly uptake rates were analysed across four periods: pre-COVID-19, COVID-19, post-COVID-19 recovery, and post-Healthier XX implementation. Segmented time-series regression was used to evaluate changes in trends associated with programme implementation. Subgroup analyses compared patients with prior preventive care utilisation to non-utilisers.

Results: Enrolment was more likely among older adults, women, married individuals, and patients with chronic conditions, and less likely among ethnic minority groups, smokers, and residents of lower-income housing. Cervical cancer screening declined during COVID-19 and partially recovered thereafter, with significant post–Healthier XX acceleration among enrolees, while uptake among non-enrolees declined. Cardiovascular risk screening showed high baseline uptake with gradual deceleration and minimal post–Healthier XX acceleration, consistent with a ceiling effect. Influenza and pneumococcal vaccination uptake increased among enrolees but stagnated or declined among non-enrolees. Among prior utilisers, cervical cancer screening recovered stronger among enrolees. Cardiovascular risk screening in non-enrolees experienced a sustained decline post COVID-19. Among prior non-

utilisers, cervical cancer screening improved gradually with greater gains after enrolment, while cardiovascular risk screening increased modestly, with declining trends among non-enrolees.

Discussion: Patient enrolment within a structured primary care reform was associated with improved recovery and divergence in preventive care uptake after the pandemic. However, benefits varied across services and reflected persistent sociodemographic inequities.

Conclusion: Healthier XX enrolment was associated with improved recovery of selected preventive services in public primary care post pandemic. Complementary strategies targeting under-represented groups are needed to maximise equitable population-level impact.

ID 1379- Could be diabetes mellitus a risk factor for leukemia?

Hung-Keng WU, Hsin-Hsuan CHUNG, Yi-Wen TSAI

Department Of Family Medicine, Chang Gung Memorial Hospital, Taiwan, Taoyuan, Taïwan

Context: Physical fitness is an important determinant of work ability and is closely associated with work quality, productivity, and overall job satisfaction. In hospital settings, where employees are exposed to sustained physical and psychological demands, impaired physical fitness compromise occupational performance and long-term health. However, the relative contributions of physical, mental, and subjective health factors to physical fitness risk among hospital employees remain unclear.

Objectives: This study aimed to examine independent factors associated with a high risk of physical fitness impairment among hospital employees, with a particular focus on whether these associations differ according to work tenure.

Methods: This cross-sectional study stratified participants by work tenure into those with less than 10 years and those with ≥10 years of employment. Binary logistic regression analyses were performed to identify independent predictors of high risk of physical fitness impairment, adjusting for potential confounders including age, sex, BMI, Waist-to-Hip Ratio (WHR), skeletal muscle mass, and health-related quality of life domains derived from the SF-36 questionnaire (Physical Component Summary [PCS], Mental Component Summary [MCS], and General Health [GH]). Tenure-stratified models were further conducted.

Results: A total of 365 hospital employees were enrolled. In tenure-stratified analyses, subjective general health (GH) was independently associated with a high risk of physical fitness impairment among employees with ≥10 years of tenure (OR 0.27, 95% CI 0.12–0.62; p = 0.002), whereas PCS and MCS were not significantly associated with physical fitness risk. In this group, higher BMI and WHR were positively associated with physical fitness impairment, while greater skeletal muscle mass and sex were inversely associated with physical fitness risk. In contrast, no significant independent predictors were identified among employees with less than 10 years of tenure.

Discussion: Among long-tenured hospital employees, subjective general health emerged as a key predictor of physical fitness impairment, outperforming conventional physical and mental health scores. These findings suggest that subjective health perception may capture cumulative occupational and metabolic burdens that are not reflected by traditional health metrics.

Conclusion: Our results indicate that tenure-specific strategies incorporating subjective health assessment may enhance the effectiveness of workplace physical fitness and health promotion programs.

ID 772- Could it have been different

Maria ZAMPARELLA, Manuel NUZZOLESE, Giacoma LANZILLOTTA

Siicp, Bari, Italie

Context: Vaccination is recognized as one of the most effective public health tools. While

European confidence remains high (82%–90%), the post-COVID-19 scenario in Italy has introduced complexity. The pandemic exposed regional heterogeneity and a decline in adherence, particularly in Southern Italy, reflecting the complex issue of Vaccine Hesitancy. Understanding the cultural, social, and communication factors influencing this hesitancy is essential for effective vaccination programs.

Objectives: This survey aimed to analyze the attitudes and opinions of the Apulian population regarding vaccine prevention, compliance, adherence, hesitancy, and the perceived quality of the Vaccination Service. We will identify factors that impede or favor adherence, improve the regional healthcare system's listening capacity, and develop a more dynamic and culturally sensitive communication model for an optimal vaccination program.

Methods: The survey involved an adult population using an anonymous 17-question questionnaire. The first phase (June–September 2025) was conducted online. A second phase will enhance proximity medicine by setting up stands in supermarkets, churches, and cinemas.

Results: Of the 250 completed questionnaires: 94% expressed confidence in vaccines, and 95% view vaccination as an effective tool.93% are aware of the free adult vaccine offer (influenza, pneumococcal, Herpes zoster).The General Practitioner (GP) is the primary information source for 70%.Hesitancy persists: 55% would not take the influenza vaccine, and 33% avoid all vaccines proposed by their GP due to fear of interactions.96.8% consider it essential to combat online misinformation, while 92.4% believe health policy should promote vaccination through media.70.4% believe incentivization and engagement tools, especially through proximity medicine, can boost trust.

Discussion: The results reveal a paradox: high awareness of efficacy (95%) and trust (94%) coexist with specific fears. The GP is a therapeutic pillar (70%), but the digital sphere presents an ambivalent challenge—a source of misinformation yet also a channel citizens want institutions to use more actively.

Conclusion: The findings confirm that to ensure complete protection, a simple active offer is insufficient. The key to overcoming hesitancy is proximity medicine and a bidirectional communication strategy based on listening. The Apulian health system's challenge is to combine scientific rigor with dynamic communication to counteract online misinformation and transform hesitancy into conscious adherence.

ID 1942- Craniosynostosis: challenges in the early diagnosis and treatment pathway of a rare disease in XXX based on a case report

Crishantha WIJAYANAYAKA

Police Hospital, Maharagama, Sri lanka

Context: Intermittent drowsiness in elder people is a frequent clinical picture caused by chronic medical illnesses, polypharmacy, dehydration, or physiological alterations connected to aging. Recurrent or unexplained hyponatremia should be thoroughly investigated, as it might suggest an underlying endocrine disorder. This case presents a rare but clinically important reason for recurrent hyponatremia stemming from hypopituitarism caused by a non-functioning pituitary macroadenoma.

Methods: We report the case of a 67-year-old retired police officer who visited the general practice with a few days of lethargy, somnolence, and intermittent drowsiness. His medical history included type 2 diabetes mellitus, hypothyroidism, coronary heart disease, and previous episodes of hyponatremia. He was hospitalized with a referral letter for further assessment. The first tests ruled out hematological, metabolic, renal, hepatic, cardiac, and medication-related issues. An extensive endocrine evaluation was performed, including serum cortisol, adrenocorticotropic hormone (ACTH),

gonadotropins, and magnetic resonance imaging of the pituitary gland.

Originality: This case is important because it brings out hypopituitarism as an uncommon and often neglected cause of recurrent hyponatremia in the elderly, especially when the patients have multiple comorbidities that may hide the original diagnosis.

Lessons learned and future implications: Recurrent hyponatraemia must never be classified as idiopathic. The workup must include endocrine causes, especially secondary adrenal insufficiency, when the common aetiologies are ruled out. The timely diagnosis and adequate hormone replacement therapy may contribute to the fast clinical improvement and the prevention of the occurrence of possibly life-threatening complications.

Discussion: In the case of this patient, hyponatremia in the aged population was likely multifactorial and probably wrongly thought to be caused by the chronic disease or medications. Secondary adrenal insufficiency as a result of impaired pituitary function led to decreased cortisol-induced free water excretion that caused repeated hyponatremia and neurocognitive symptoms. The thorough evaluation and constant care of the patient were crucial in uncovering the hidden cause.

Conclusion: The case presented here illustrates the necessity of detailed assessment of recurrent hyponatremia in the elderly and draws attention to hypopituitarism resulting from a non-functioning pituitary macroadenoma as an infrequent but curable cause. Timely identification through a holistic approach can dramatically enhance patients' outcomes.

ID 533- Cross border learning for sustainable Out-of-hours care by general practitioners in Europe

Zoe Phyllis CARPISO, Grace ESTRADA

Southern Isabela Medical Center, Santiago City, Philippines

Context: Trigeminal neuropathy (TNO) presents diagnostic challenges in primary care, often requiring multidisciplinary work-ups to rule out serious etiologies. This case of a 57-year-old female with progressive facial numbness explores Fraternity by integrating traditional family medicine with integrative medicine to enhance outcomes when conventional treatments are limited.

Methods: A 57-year-old female presented with a one-year history of progressive right-sided facial numbness. A comprehensive work-up, including neurological exams, hypertensive screening, cranial CT, syphilis screening, and inflammatory markers (CRP/ESR), ruled out malignancy, vascular compression, infection, and inflammatory causes. While findings of dyslipidemia and peripheral lipomatosis were noted, they were deemed unrelated. The patient was referred for integrative medicine and received three 15-minute acupuncture sessions (1–2 week intervals) utilizing acupoints ST6, ST7, GB14, GB26, LI20, Yin Tang, and Tae Yang.

Originality: This case demonstrates an innovative "Fraternity of Care" by utilizing acupuncture not as a secondary alternative, but as a coordinated first-line non-pharmacological intervention within a tertiary hospital's Family Medicine department. It highlights the Family Physician's role in bridge-building between high-tech diagnostics (CT imaging) and traditional needle-based therapies.

Lessons learned and future implications: The key lesson is that integrative medicine safely alleviates TNO symptoms. Formalizing interprofessional referral networks is vital to ensure equitable access to diagnostics and non-pharmacological symptom management.

Discussion: The management of this case highlights the clinical challenge of trigeminal neuropathy, where standard pharmacological treatments often carry side-effect profiles that patients may find unacceptable. By utilizing the Numbness Numerical Rating Scale, we were able to quantify the success of a non-pharmacological intervention. The reduction in symptoms from moderate to low suggests that

medical acupuncture can effectively modulate sensory deficits. Furthermore, the psychological relief expressed by the patient after ruling out malignancy underscores the importance of the Family Physician's role in providing reassurance alongside physical treatment

Conclusion: In conclusion, trigeminal neuropathy requires a dual approach: rigorous diagnostic work-up to rule out poor-prognosis etiologies and an open-minded therapeutic strategy. This case demonstrates that medical acupuncture is a safe and viable adjunct in primary care. This illustrates Fraternity by showing how diverse practices coexist to provide holistic care.

ID 1988- Cross-border project on primary prevention – PREVENT. Issues for improvement in primary healthcare

Jane SMITH

Bond University, Gold Coast, Australie

Context: Around the world there is a decline in graduates choosing a career in general practice(GP). This is despite data showing strengthening GP and GP continuity of care leads to improved health, lower mortality, and reduced healthcare-system costs. Many countries rely on importing GPs from other countries, who provide great value. Ideally capturing home grown doctors We have data showing our medical program has the highest percentage ot graduates choosing to work in metropolitan general practice in the country. This presentation will reflect on the national statistics and the elements of our medical education that are associated with inspiring graduates to choose the specialty of general practice.

Methods: The national analysis on GP trainees is based on data of graduates from all medical schools in our country. This data will be shared along with specific characteristics of university medical school education programs that appear to cause a higher percentage of graduates to choose general practice as their training pathway. Insights about rural GP training pathways will be included in this data.

Originality: This national data of all medical graduates in our country was generated for the first time in 2025. The results were not intuitive nor anticipated, as they were different to expected. Many previous papers have looked at characteristics that are associated with working in rural GP, or career intentions of new graduates; this reveals genuine GP training intent. This is why it is important to reach better understanding of what the drivers are in a medical graduate's education to make them more likely to want to be a GP.

Lessons learned and future implications: The percentage of medical graduates choosing general practice varied from 52% down to 16%. The insights gained from comparing different approaches used in medical education and clinical placements between the universities with greater success in producing GPs will help improve graduate career choice in GP.

Discussion: The national data combined with information about university GP training (in clinic or classroom) highlights the essential design ingredients of medical training to enhance graduate choice of GP.

Conclusion: Graduates have a higher interest in GP than thought and the medical schools producing GPs can be a surprise.

ID 1838- Cultivating positive mental attitude to protect against depression in medical trainees: implications for holistic care and education

Yaazhini NIL

Singapore, Singapore, Singapour

Context: Nausea and vomiting are common presentations in family medicine and are often attributed to acute infection, migraine, or self-limiting gastrointestinal illness. When symptoms persist or recur, especially in the presence of competing diagnoses, underlying systemic causes such as hyperthyroidism may be overlooked.

Methods: We present a descriptive case report of a 39-year-old woman whose diagnosis emerged through serial reassessment during an acute admission and integration of longitudinal clinical history across multiple healthcare encounters.

Originality: This case illustrates a gastrointestinal-predominant presentation of Graves disease complicated by concurrent bacterial tonsillitis and a history of migraine, highlighting the diagnostic challenge of symptom overlap in primary care.

Lessons learned and future implications: Persistent symptoms despite appropriate treatment should prompt clinicians to revisit the differential diagnosis. Recurrent tachycardia and menstrual irregularities may be important clues to an underlying endocrine disorder. A longitudinal, whole-person approach may reduce diagnostic delay and repeated healthcare utilisation.

Discussion: A 39-year-old woman with well-controlled asthma and episodic migraines presented with fever, cough, sore throat, and one week of recurrent vomiting, escalating to approximately 20 episodes on the day of admission and associated with epigastric pain. Examination revealed tachycardia (heart rate 110 bpm), bilateral tonsillar exudates, epigastric tenderness, and possible neck fullness that was difficult to assess due to body habitus. Initial investigations showed leukocytosis with neutrophilia and mild hypokalaemia, with otherwise unremarkable renal and liver function tests. She was treated for bilateral bacterial tonsillitis with oral amoxicillin-clavulanate and symptomatic therapy for presumed post-tussive and migraine-related vomiting. While respiratory symptoms and headaches improved, vomiting persisted. Further history revealed recurrent gastrointestinal disturbances, intermittent unexplained tachycardia documented during prior clinic and emergency visits, and irregular menstrual cycles over the preceding year. Thyroid function testing demonstrated suppressed TSH, markedly elevated free T4, and positive thyroid antibodies, confirming Graves disease. Carbimazole was initiated with subsequent clinical and biochemical improvement.

Conclusion: Hyperthyroidism should be considered in patients with persistent or recurrent nausea and vomiting, particularly when accompanied by systemic features such as tachycardia or menstrual irregularities. This case highlights the value of continuity of care and reflective reassessment in family medicine to prevent diagnostic delay.

ID 272- Current knowledge on the management of ankle sprains in primary care: a systematic review of the literature

Claire PICATTO

Aix Marseille University, Remire Montjoly, Guyane française

Context: Ikairos Culture du Soin is a non-profit organization created in 2023 by Doctors Cloé Brami and Solène Blanchin in response to the deteriorating mental health of healthcare students. Since January 2025, it offers multi-monthly videoconference workshops in mind-body practices. These workshops are led by healthcare professionals and are reserved for health students. Despite regular communication on social media and contact with 37 french universities, very few students participate in the workshops. This contrasts with the catastrophic state of mental health among french medical students: according to a 2024 survey(1): 21% of students experience suicidal thoughts, 52% experience anxiety symptoms, 66% suffer from burnout, 24% have eating disorders. The need for solutions is urgent. The main hypothesis is that our communication strategy is inadequate. How can we be attractive for students? What tools exist in other European countries? 1. Anemf , Isnar -IMG, Isni +. Survey on the mental health of medical students from the second year to the end of their residency [Press kit]. 2024

Methods: We do the presentation with a PowerPoint, questioning participants about their knowledge of the state of mental health and existing support in France, the post-it note

method to explore communication barriers and participants' expectations.

Originality: This presentation is intended to be interactive.

Lessons learned and future implications: This presentation aims to present the association, to raise awareness among workshop participants about the mental health challenges faced by healthcare students; to provide an overview of existing resources and the role of the association's services.

Discussion: We want to gather the experiences of the different participants, their expectations, and to leave with concrete actions to implement.

Conclusion: This presentation has a triple objective: to highlight the alarming state of mental health among health students; to raise awareness of Ikairos Culture du soin; to reflect together on how to improve the availability of the association's workshops to students.

ID 197- Current Status and Challenges of Policies to Strengthen Regional, Essential, and Public Healthcare in Korea: Health Equity-Oriented Health Policy Analysis

Aleksandra JESIC, Dragana KOPANJA, Tatjana MLADENOVIC

Health Center Dz New Belgrade, Belgrade, Serbie

Context: The World Health Organization recognizes aging as an important factor in the development of dementia. Statistical data show that the risk of dementia increases with age. More than 65% of dementia cases occur in individuals older than 65 years, while in the age group over 85 years this figure exceeds 30%. Aging is associated with other risk factors that contribute to the development of dementia (hypertension, diabetes, cardiovascular diseases, lack of physical activity, level of education, depression, etc.).

Objectives: The aim of this study was to assess the cognitive status of patients with comorbidities and apparently preserved cognition in our medical records. The objective was to determine the prevalence of mild cognitive impairment (MCI) and to analyze the association between cognitive decline and predictors of dementia among patients in our practice.

Methods: Anamnestic data and laboratory analyses from available medical documentation were used. Cognitive abilities were assessed using the Montreal Cognitive Assessment (MoCA) test. A total of 200 patients from two medical practices were tested: 89 men and 111 women, aged 50 years and older.

Results: Thirty-one percent of the participants had MoCA test results consistent with MCI. In the group aged 85 and older, 83% (5/6) had findings indicative of MCI. In the group aged 50–64 years, 14% showed results suggesting MCI. The prevalence of MCI was significantly higher among participants with up to 12 years of formal education (45% vs. 20%). Most tested participants had elevated LDL cholesterol and blood glucose levels. Hypertension, cardiovascular disease, and type 2 diabetes mellitus were equally represented in both groups. Only mood disorders were significantly more prevalent in the group with MCI (31% vs. 7%).

Discussion: Previous research highlights the importance of lifestyle modification at the earliest possible stage. According to a recent report by the nonprofit research organization RAND, cognitive abilities, functional limitations, and physical health may be strong predictors of dementia risk up to 20 years before its onset. Certain lifestyle choices made at the age of 60 may indicate an increased risk of dementia later in life.

Conclusion: Risk factors, as significant predictors, influence the prevalence of MCI regardless of age group and comorbidities.

ID 593- Cutaneous leishmaniasis in a non-endemic area in Tunisia

Mustapha BELLIL

Amgo, Bir El Djir, Algérie

Context: In Algeria, general practice extends beyond its traditional clinical scope to engage with the judicial domain. Owing to their close relationship with patients and communities, general practitioners provide distinctive credibility and relevance in medico-legal expertise.

Objectives: This work aims to present and critically analyze nineteen years of professional experience in judicial expertise, highlighting the specific challenges encountered, the contributions made, and the strategic role of general practitioners within both the healthcare and judicial systems.

Teaching method and workshop: A retrospective and descriptive approach was employed, based on the systematic review of cases handled and the classification of disputes across civil and criminal contexts.

Expected outcomes: - A broad spectrum of cases was addressed, encompassing civil and criminal litigation. - Ongoing professional development in medical law and expert methodology proved indispensable. - The general practitioner emerged as a trusted intermediary, combining

Conclusion: General practice can play a pivotal role in judicial expertise. This experience underscores the importance of integrating medico-legal expertise into the training of general practitioners and of fostering stronger dialogue between medicine and justice, both in Algeria and on the international stage.

ID 177- Dapagliflozin Eligibility and Renal Testing Gaps in Chronic Kidney Disease: A Retrospective Cross-Sectional Analysis in Primary Care

Naajiyah KATHRADA, Cassian MINGUET, Sarah CUMPS

Camg, Uclouvain, Brussels, Belgique

Context: General practitioners routinely work with clinical situations shaped by social conditions, cultural meanings, chronic illness and ethical tensions. A workshop delivered at WONCA 2025 introduced medical anthropology as a conceptual lens, enabling participants to make explicit forms of reasoning already used implicitly in everyday consultations. Feedback from this workshop raised a recurring question: how can anthropological perspectives be translated into practical methods that both enrich clinical work and support engagement in qualitative research grounded in general practice?

Objectives: This workshop aims to help participants recognise observation and attention as skills that can be developed in general practice. Participants will practice a simple anthropological observation exercise applicable to everyday consultations, understand how careful observation generates relevant clinical and research questions and identify how these skills can support reflective practice and the early stages of qualitative inquiry.

Teaching method and workshop: The workshop is built around a single practical observation exercise inspired by the work of Nicolas Nova, a renowned anthropologist, who conceptualises observation as a cognitive capacity that requires training. The session opens with a brief summary of

Expected outcomes: Participants will gain a concrete, low-threshold tool to strengthen observational and reflexive capacities already present in everyday general practice. By making these practices explicit, the workshop supports more attentive, patient-centred consultation

Conclusion: By building on skills that general practitioners already use in routine practice, this workshop shows that engaging in qualitative research does not require complex methods and separation from clinical work. Medical anthropology is presented as a practical and accessible resource that supports clinical reflection while opening realistic pathways into qualitative research within everyday general practice.

Context: Actinomycosis is a chronic, suppurative, and granulomatous bacterial infection, primarily caused by filamentous, Gram-positive, anaerobic bacilli of the genus Actinomyces. These bacteria, which are commensal flora of the oropharyngeal, digestive, and genital mucous membranes, become pathogenic when the integrity of the barriers is breached. They then cause abscesses, fistulas, and pseudo-tumoral lesions often mistaken for neoplasia or tuberculosis.

Objectives: To identify the epidemiological, clinical, and paraclinical characteristics of actinomycosis. To analyze the therapeutic approaches for patients managed for actinomycosis.

Methods: A descriptive retrospective study focusing on 22 cases of actinomycosis diagnosed between January 1998 and June 2025. Demographic, clinical, paraclinical, therapeutic, and outcome data were analyzed using SPSS software (version 26). Student's t-test was used to analyze the predisposing factors for actinomycosis infection.

Results: The mean age at diagnosis was 49 years, with a female predominance (male/female sex ratio = 0.83). Predisposing factors were identified in 63% of patients, mainly the use of an intrauterine device (IUD) with a statistically significant difference (p = 0.005) and poor oral hygiene. Abdominopelvic localization (41%) was the most frequent, followed by cervicofacial, cerebral, and cutaneous forms. Diagnosis was confirmed by anatomopathological examination in 91% of cases and by bacteriology in 9%. All patients received prolonged antibiotic therapy, primarily based on penicillin G or amoxicillin, for an average duration of 10 months. Surgical management was necessary in 68% of patients. The outcome was favorable in 68% of cases, with two relapses and one death.

Discussion: Actinomycosis is a rare, chronic bacterial infection with slow progression. It is characterized by the formation of multiple abscesses, fistulous tracts, and the presence of so-called “sulfur granules.” Diagnosis relies on bacteriological identification and histopathological examination. Management is based on prolonged antibiotic therapy, mainly penicillin, sometimes combined with targeted surgical intervention. The incidence has decreased due to improved oral hygiene and better access to antibiotics.

Conclusion: Actinomycosis remains a rare and often unrecognized condition, whose polymorphic clinical presentation can simulate a malignant tumor. Early diagnosis and appropriate, prolonged antibiotic therapy, associated with surgery if necessary, allow for an excellent prognosis. Prevention relies on better oral hygiene and the monitoring of women with IUDs.

Context: The COVID-19 pandemic accelerated moves towards the virtual delivery of primary care in Canada. As this occurred, debates over how virtual primary care (VPC) ought to be encouraged or discouraged, governed and paid for have intensified. Within these high-level debates there has been little attention paid to the details of which technologies are being

deployed to deliver VPC and how those technologies interact with non-technical factors to ensure efficiency and effectiveness.

Objectives: With a policy-making audience in mind, the research sought to: 1) identify the various constellations of VPC technology that are being deployed; 2) characterize how key informants see them working and to what purpose; and 3) describe how those technologies are interacting with non-technical factors to shape success to care.

Methods: 29 qualitative interviews with mid-level VPC experts from the provinces of Alberta, Nova Scotia, and Ontario. Data were coded and analyzed using an Interpretive Description approach.

Results: From basic phone calls to advanced multi-platform multi-disciplinary case conferences, participants saw VPC technologies as improving access to primary care by increasing efficiency and coordination. Specifically VPC was deployed to improve the accessibility, availability, and accommodativeness of care. VPC technologies interacted with and relied on: human efforts, funding models, and the institutional contexts in which they were deployed.
