Discussion: From a policy-making perspective, the effectiveness and sustainability of VPC technologies were strongly influenced by human rather than purely technical factors. Finding ways to support and icentivize the social networks that underpin effective VPC interventions will be important to ensuring their sustainability. Policy makers may want to consider adjustments to funding models, and supports for cultural change within the institutions of primary care.

Conclusion: Policy-makers seeking to optimize VPC will want to consider ways to support not just purchases of technology, but: the human effort required to choose and manage technology; the funding mechanisms that incentivize the efficient use technology; and the institutional contexts and cultures that underpin access improvements through technology.

ID 744- Decision support tools for lung cancer screening

Rachel PHILLIPS, Kyle MATTHEWS, Paul JONES

Rcgp Scotland, Edinburgh, Royaume-Uni

Context: Europe has the highest proprotion of drinkers worldwide and experiences the largest burden of alcohol harms. Sometimes this is obvious, but often its subtle and disproportionately affects deprived populations. It's up to us to bring the topic of alcohol into the consultation and how we do this is a nuanced part of our craft. Some GPs will have a natural ability, but the rest of us can improve.

Objectives: Outline the alcohol harms that present in GP - the obvious and hidden. Explore what effective conversations about alcohol could look like Explain some physiology and psychology of addiction Introduce concept of relational injury Highlight importance of signposting with conviction to recovery resources Discuss how to hold the hope when patients feel helpless Exposure to recovery

Teaching method and workshop: Introduction from our context - GP in Scotland, the alcohol harms we see in daily practice. Structured technique to draw out from participants: -- the alcohol-related harms in their own practice (obvious and hidden) -- positive and negative experiences of

Expected outcomes: Highlight hidden harms that alcohol causes in our patients and ourselves. Explore what a GP can realistically offer - our role in identifiying alcohol harm, linking alcohol to presenting complaints, skillfil conversation, reducing healthcare stigma, commu

Conclusion: How we talk to patients matters. It influences their agency to recognise and change unhealthy drinking behaviour and their perception of healthcare stigma. In Scotland, one in five patients we see every day drink harmful levels of alcohol. But we are not alone as Europe bears the highest worlwide burden of alcohol related harm. We hope prompt

insights that could make a difference to participants' next clinic.

Context: Arterial hypertension remains one of the leading modifiable risk factors for cardiovascular morbidity and mortality worldwide. Although effective antihypertensive treatments are widely available, a considerable proportion of patients fail to achieve recommended blood pressure targets when treated with monotherapy. Both international and Greek guidelines emphasize the early initiation of combination therapy, preferably in the form of single-pill combinations (SPCs), in order to improve adherence and clinical outcomes.

Objectives: The objective of this study was to review the available evidence regarding the use of single-pill combinations in Greece and internationally, and to identify discrepancies between guideline recommendations and real-world clinical practice.

Methods: A narrative review of the Greek and international literature was conducted using the PubMed, Scopus, and Google Scholar databases. In addition, current guidelines from the European Society of Cardiology/European Society of Hypertension (ESC/ESH) and the Hellenic Society of Hypertension were reviewed. Data on national and international SPC utilization rates, as well as factors influencing their implementation, were analyzed.

Results: In Greece, no published national or regional data are available regarding SPC utilization. Relevant prescribing data are theoretically accessible through the national e-prescription system (IDIKA), but have not been publicly released. In high-income countries, the mean SPC utilization rate is approximately 24%, with reported rates of 10.9% in Germany (2020) and a range of 10–30% across Europe. In contrast, SPC use reaches approximately 45% in low- and middle-income countries, largely due to public health policies and interventions supported by the World Health Organization. Available evidence consistently demonstrates that SPCs are associated with improved treatment adherence and higher rates of blood pressure control compared with free-drug combinations or monotherapy.

Discussion: Despite strong guideline recommendations, SPC adoption remains suboptimal, particularly in high-income countries such as Greece. Limited access to national prescribing data, clinical inertia, and insufficient dissemination of evidence-based combination strategies appear to contribute to this gap.

Conclusion: A significant discrepancy exists between hypertension management guidelines and real-world SPC use in Greece and internationally. Systematic recording and public disclosure of national prescribing data, along with the promotion of evidence-based SPCs, are essential to improve blood pressure control and reduce cardiovascular risk.

Context: Diabetes mellitus (DM) has a significant impact on women's health, increasing susceptibility to both infectious and non-infectious vulvovaginal disorders. Alterations in glucose metabolism may disrupt the normal vaginal environment and predispose to recurrent infections.

Objectives: To investigate the association between poor glycemic control in diabetes mellitus and the increased incidence of vulvovaginal infections.

Methods: Vaginal discharge examination results collected over a one-year period from a clinical microbiology laboratory in the Piraeus area were retrospectively analyzed. Microscopic examination was initially performed, followed by amine testing, cultures for aerobic and anaerobic bacteria, Mycoplasma and Ureaplasma species, and monoclonal antibody testing for the detection of Chlamydia trachomatis.

Results: A total of 120 positive cases were identified. Of these, 72 cases involved diabetic patients with fasting blood glucose levels exceeding 140 mg/dL, while 48 cases involved non-diabetic patients. Among diabetic patients, 49 were positive for Candida albicans, 2 for Trichomonas vaginalis, 16 for Gardnerella vaginalis, 1 for Chlamydia trachomatis, and 4 for Mycoplasma hominis. Among non-diabetic patients, 20 were positive for Candida albicans, 5 for Trichomonas vaginalis, 6 for Gardnerella vaginalis, 6 for Chlamydia trachomatis, and 11 for Mycoplasma hominis.

Discussion: The findings demonstrate a higher prevalence of vulvovaginal infections among women with poorly controlled diabetes, particularly fungal infections caused by Candida albicans. Hyperglycemia may alter vaginal pH and impair local immune defenses, thereby facilitating the growth of pathogenic microorganisms.

Conclusion: Poor glycemic control is strongly associated with frequent and recurrent vulvovaginal infections. Effective regulation of blood glucose levels may play a crucial role in preventing vulvovaginal infections and improving gynecological health in women with diabetes mellitus.

ID 1402- Delivering Culturally Sensitive, Holistic Care in Rural and Urban Settings: Twenty Years of Family Medicine Practice

Steven VAN DE VIJVER [1] , Ana Luisa NEVES [2], Edmond LI [2], Joanna FERREIRA TEIXEIRA [2]

(1) Olvg, Amsterdam, Pays-Bas
(2) Imperial College, London, Royaume-Uni

Context: Digital health is rapidly changing how people interact with primary care. Information, decision-support and navigation tools are moving closer to citizens, who increasingly expect accessible, personalised and timely support. At the same time, primary care systems face growing pressure due to ageing populations, increasing multimorbidity and workforce shortages. Person-centred digital solutions offer opportunities to support self-management, preventive behaviours and shared decision-making, while helping to use limited resources more effectively. One emerging approach is the Digital Frontdoor: a digital entry point that supports citizens at their first contact with the health system. Typical user-facing functions include symptom checkers, structured intake and consent tools, appointment planning, self-care guidance and links to primary care, community and social services. Increasingly, these tools are supported by generative artificial intelligence (GenAI), enabling more personalised guidance, effective triage and appropriate referrals. When well designed and embedded in care pathways, Digital Frontdoors can improve citizen experiences while supporting sustainable primary care workflows. To realise this potential, digital innovations must be usable, trustworthy, inclusive and aligned with clinical and community-based care. International exchange of experiences and lessons learned is therefore essential. The Amsterdam Digital Frontdoor provides one practical example, alongside other emerging person-centred digital health models relevant across diverse contexts.

Objectives: - Explore how person-centred design strengthens digital primary care - Present the Amsterdam Digital Frontdoor as a

best-practice case - Identify benefits, challenges and contextual factors influencing implementation - Exchange international examples and lessons learned in person-centred digital primary care

Teaching method and workshop: After a short introduction, facilitators will present the Digital Frontdoor concept and case example. Participants will discuss benefits, challenges and comparable initiatives in small groups, followed by a plenary synthesis.

Expected outcomes: Participants will gain practical insights into how person-centred digital tools can strengthen primary care and improve system responsiveness. Key themes will be synthesised into actionable recommendations, and hopefully potential publication.

Conclusion: This workshop will support shared learning on how person-centred tools like Digital Frontdoors and related innovations can contribute to more equitable, effective primary health care.

Context: Subjective age has been linked to health outcomes, including functional decline and increased mortality risk. However, its utility in primary care settings remains underexplored.

Objectives: This study aimed to evaluate whether the question "How old do you feel?" could enhance physician-patient communication.

Methods: In this observational study, thirteen primary care physicians (PCPs) asked 194 patients aged 50 and older the question "How old do you feel?" during clinical encounters. Following each encounter, PCPs completed a questionnaire to assess the impact of the question on the consultation. Data were analyzed using descriptive statistics, and univariate analysis was performed with a mixed-effects logistic regression model to identify factors influencing physicians' perceptions of the question's utility. We also evaluated their free-text responses to understand their perceptions of this question.

Results: PCPs reported positive experiences, with 74% of consultations leading to further discussions, and 80% of PCPs felt the question improved their understanding of the patient. Sixty-two percent believed the question benefited the patient. Factors such as physician age, experience, and patient multimorbidity were significantly associated with positive perceptions of the question's utility.

Discussion: This study suggests that asking "How old do you feel?" can enhance communication between PCPs and patients, providing valuable insights into patients' overall well-being. This question may help identify vulnerable patients and improve care.

Conclusion: Future studies should explore its broader applicability and long-term effects in diverse primary care settings to assess its potential as a standard tool in clinical practice.

Context: Ageism in healthcare may negatively impact the care provided to older adults.

Objectives: This study aimed to examine whether ageist attitudes exist among family physicians, internists, and geriatricians using the Kogan's Attitudes Toward Older People questionnaire.

Methods: This cross-sectional survey was conducted between July and December 2024. The Kogan questionnaire includes 34 items scored on a continuous scale, with higher scores indicating more positive attitudes toward older individuals. A total of 121 physicians (family medicine, internal medicine, and geriatrics) participated. Data were analyzed using ANOVA, Kruskal-Wallis, and Chi-square tests. Internal consistency of the questionnaire was assessed using Cronbach's alpha. Correlations between self-perceived ageism and questionnaire scores were evaluated using Pearson's correlation coefficient.

Results: There were no statistically significant differences in overall ageism scores between family physicians, internists, and geriatricians (mean scores: 93.3, 94.1, and 91.7 respectively; $p = 0.867$). Importantly, the scores of all physician groups were below the questionnaire's theoretical median, indicating a generally more negative attitude toward older individuals. A weak to moderate correlation was found between self-perceived ageism and the total score of the questionnaire ($r = 0.246$, $p < 0.01$). A stronger correlation was noted between self-perception and the Prejudice Index ($r = 0.328$, $p < 0.001$). Among geriatricians specifically, a strong correlation was observed between self-perception and the total score ($r = 0.622$, $p < 0.01$). However, in most cases, self-perception did not align with the attitudes objectively measured.

Discussion: This study found no significant differences in ageist attitudes among physician specialties. Overall scores were below the theoretical median, suggesting generally negative attitudes toward older adults. The discrepancy between self-perceived and measured attitudes highlights the need for targeted education and reflective training.

Conclusion: Raising awareness of ageism in clinical practice is essential to fostering respectful, equitable care for the aging population.

ID 1272- Deprivation index of Patients Seen by Medical Students During Primary Care Placements

Eman ALI

Faris Al Lami, Baghdad, Iraq

Context: The World Health Organization defines mass gatherings (MGs) as planned or spontaneous events where the number of attendees could strain the community or country's resources for planning and response. MGs may pertain to sports, religion, politics, art, or various other activities. In recent decades, the frequency of MGs and the number of participants has increased due to greater population mobility. These gatherings can pose various health hazards that elevate the risk of morbidity and mortality for both the local population and attendees.

Methods: practice based observations base on preparation and participation of several mass gatherings events

Originality: It is parctice base study is observational in nature. practice base orientaion

Lessons learned and future implications: . This study aims to delineate the role of General Practitioners (GPs) in ensuring the safety of MGs through activities implemented before, during, and after the event.

Discussion: Before the event, GPs can conduct risk assessments to identify potential health threats, including communicable and non-communicable diseases, injuries, and environmental risks. They can promote a culture of preparedness by contributing to the development of emergency preparedness and response plans, tailored to the event's demographics and context. These can include developing protocols, healthcare access routes, vaccination activities, implementing health education programs, ensuring adequate medical resources are available, and training event staff in basic first aid and emergency response. During the event, GPs can collaborate with local health authorities to enhance event-based and disease-based surveillance of potential health risks and to

ensure a prompt response to prevent outbreaks, reduce morbidity and mortality, and mitigate the burden on the health system. After the event, GPs must remain vigilant for potential outbreaks of communicable diseases with long incubation periods (that exceed the MG duration) that may emerge in the local community or among visitors returning home. GPs can participate in post-event evaluations to identify strengths and gaps and inform strategies for future MGs.

Conclusion: The involvement of GPs is vital for comprehensive planning to minimize health risks, ensure a swift response to medical emergencies, and foster a safe environment during MGs. They also provide invaluable guidance to travelers attending these events, helping protect both individual health and community well-being.

Context: Digital health technologies such as wearables shape the everyday lives and health awareness of patients - also in primary care settings. These tools offer opportunities for individual patient-centred care, yet there is a need for practical and evaluated methods to use these technologies meaningfully in clinical practice - as part of a holistic treatment approach. This study explores a wearable-informed physician consultation on basis of the biopsychosocial model that could be translated into primary care settings.

Objectives: Our goal was to investigate if a physician consultation based on a 24-hour heart rate variability (HRV) spectrograph combined with a diary increased the notice of interactions between thoughts, feelings and bodily reactions compared to controls.

Methods: A randomized controlled trial was conducted with one hundred managers from a manufacturing and engineering company, randomized into an intervention (IG) or control group (CG). The IG underwent a 24-hour ECG (Electrocardiogram) measurement, documented daily events and completed questionnaires. These data informed a 50-minute consultation, focusing on the connection between emotions, thoughts, recorded situations, and HRV. Questionnaires were repeated after three months. Changes in the primary outcome - awareness of biopsychosocial interactions - were analysed using repeated-measures ANOVA.

Results: Data from 81 participants with complete HRV and questionnaire data were included in the final analysis. Participants (94% male, mean ±SD age 48±8.6 years) in the IG reported significantly increased awareness of mind-body interactions ($p=0.032$, $\eta^2=0.057$) and were more likely to respond to their body's needs ($p=0.008$, $\eta^2=0.085$). Perceived stress was significantly reduced only in the IG ($p=0.017$, $\eta^2=0.071$).

Discussion: This approach, integrating HRV visualization with diary-based reflection, proved to be a feasible and effective method for enhancing awareness of biopsychosocial processes, supporting self-regulation, promoting behavioural change and reducing perceived stress. The occupational setting with the study population of predominantly male managers may limit generalizability.

Conclusion: This study serves as a gateway for personalized preventive strategies and can complement traditional medical consultations based on wearable data. Further exploration in diverse settings, such as primary care, is recommended to fully assess its broader applicability and benefits. Keywords: primary prevention; Stress, Psychological; Heart Rate / physiology; Patient-Centered Care

ID 1040- Description of adults' perceptions of Health and behavioural correlations in a Low-Income XXX Community

Antoine GIACOMINI, Misbaou MBAE ALI

Université Strasbourg, Strasbourg, France

Context: Patients receiving opioid substitution treatment (OST) experience social vulnerability, stigma, and barriers to healthcare access. Although organized cancer screening programmes are free and widely available in France, little is known about participation rates and barriers among patients treated with OST in primary care settings.

Objectives: To assess participation in organized cancer screening programmes (breast, cervical, and colorectal cancers) among patients receiving OST in Eastern France, and to identify barriers and factors associated with non-participation.

Methods: We conducted a multicentre cross-sectional quantitative study between July 2024 and June 2025 in the Bas-Rhin and Haut-Rhin regions. Adult patients receiving methadone or buprenorphine were recruited in addiction treatment centres, general practices, hospitals, and a prison setting. Data were collected using two structured questionnaires assessing socio-demographic characteristics, screening participation, and perceived barriers. Descriptive analyses were performed, followed by univariate and multivariate logistic regression to identify factors associated with non-participation.

Results: Seventy-seven patients were included (45.5% women; mean age 49.8 years). Overall, 67.5% were not up to date with at least one recommended cancer screening. Among eligible participants, participation rates were 62.9% for cervical cancer, 40.0% for breast cancer, and 21.2% for colorectal cancer. The main barriers reported were low prioritisation of screening (35.7%), fear of cancer diagnosis (14.3%), misunderstanding of invitation letters (11.9%), perceived procedural burden (10.7%), and negative healthcare experiences (8.3%). In multivariate analysis, lower educational level and age between 45 and 55 years were independently associated with non-participation.

Discussion: Despite universal access to organized screening, patients receiving OST showed markedly lower participation than the general population, particularly for colorectal and breast cancer. Barriers were predominantly psychosocial and organisational rather than financial, highlighting the central role of health literacy and care coordination. The higher uptake of cervical screening may reflect more frequent contact with healthcare professionals. Selection and recall biases may have led to overestimation of participation, reinforcing the robustness of the observed inequalities.

Conclusion: This study highlights persistent cancer screening inequalities among patients receiving OST in primary care. Integrating proactive counselling, adapted information, and outreach or on-site screening within addiction and general practice settings could improve participation and promote equity in preventive care.

Context: Chronic kidney disease (CKD) is a common complication among individuals with diabetes, affecting approximately 30% of patients. Diabetes and CKD often co-exist with

cardiovascular disease and with additional morbidities leading to increased healthcare needs.

Objectives: To characterize the population of Israeli adults with type 2 diabetes and describe the prevalence of CKD across its different disease stages, as well as to assess additional comorbidity. We further aimed to describe the pharmacological treatment and healthcare utilization patterns at each stage.

Methods: A cross-sectional study based on medical records from one of Israel's national health maintenance organizations and including all current member aged 18 and above diagnosed with type 2 diabetes. CKD prevalence was determined based on estimated glomerular filtration rate (eGFR) and urinary albumin-to-creatinine ratio (uACR). We extracted demographic and clinical data, presence of comorbidities, information about medication use, specialist care and hospital visits.

Results: The study population included 65,349 adults with diabetes, of whom 29.7% had CKD; 18.9%, 6.2%, and 4.5% were at progressively more severe CKD stages. There was a positive association between CKD stage and various cardiovascular diseases, both before and after adjustments, the strongest of which was with heart failure reaching an adjusted relative risk of 2.5 (95% CI 2.3, 2.6) for the most severe stage compared to no CKD. Diabetic retinopathy and neuropathy were also positively associated with CKD stage reaching an adjusted relative risk of 2.1 (95% CI 2.0, 2.3) and 1.5 (95% CI 1.4, 1.5) respectively. Visits to Ophthalmologists were prevalent among more than half the population. Visits to Nephrologists, Endocrinologists, Cardiologists and Vascular surgeons were more common at more progressed CKD stages. Emergency room visits and hospitalization rates were also higher the more severe the CKD stage.

Discussion: CKD is prevalent among adults with diabetes type 2 in Israel and is associated with an increased burden of cardiovascular and other comorbidity. Healthcare utilization is higher at more severe CKD stages.

Conclusion: The global rise in diabetes calls for improved prevention and care strategies as well as healthcare resource planning and allocation of services for the substantial subgroup of patients with comorbid CKD.

ID 921- Detection of occupational respiratory disease in primary health care - a case report

Brieux LONGÉPÉ, Audrey MADEC, Jérôme FONSECA, Lucas BEURTON-COURAUD, Marie BARAIS, Delphine LE GOFF

Department Of General Practice, University Of Western Brittany, 22, Av. Camille Desmoulins, 29238 Brest, Fr, France, Brest, France

Context: The growing societal demand for general practitioner certification has led to a shift in training, focusing on competencies. To support the monitoring of competency acquisition, the University of XXX developed a criterion-referenced evaluation table referred to here as 'Exceler'.

Objectives: We aim to evaluate opinions of General practice interns in XXX about the acceptability and feasibility of using the Exceler evaluation tool to monitor competency acquisition during internships.

Methods: A qualitative approach involving game-based focus group interviews inspired by the Dixit® board game was employed. Dreamlike illustration cards facilitated group dynamics, promoted balanced participation and stimulated discussion among participants. Verbatim transcripts of the interviews were analysed using a grounded theory-inspired approach, leading to the development of a mind map.

Results: The interns expressed good acceptance of the Exceler table. Their analysis highlighted several issues with existing evaluations : the quality of the content and process was sometimes insufficient ; the lack of progression benchmarks could generate anxiety ; and adapting evaluations to individual profiles and training pathways appeared necessary. Exceler emerged as a convincing response thanks to the validity of its content,

flexibility of use, and accessibility. Reservations about its use led to suggestions for modifying the tool, which can be seen as further evidence of its acceptability.

Discussion: To our knowledge, this is the first study to report on interns' views of their evaluations using focus group interviews. The originality of the data collection method helped to minimise data loss relating to differences in participants' verbal expression and the investigator's limited experience. The completeness of the data, adherence to COREQ criteria, and triangulation of the analysis support the internal validity of the findings. The central role of supervision and the criticisms of the table raised by the participants are also consistent with the literature.

Conclusion: Exceler appears likely to improve the quality of evaluations, enrich the existing educational toolkit, and facilitate the adoption of the competency-based learning model. Analysing opinions of tutors, supervisors and other practice centers could help identify potential barriers and reveal solutions to facilitate its implementation and use.

ID 582- Determinants and consequences of geographic inequalities in the UK GP workforce

Cristina SICORSCHI GUTU

Medgate Ag, Eckental, Allemagne

Context: Telemedicine has become an increasingly important component of modern healthcare systems, offering numerous benefits for patient access, continuity of care, and system efficiency. While research on patient outcomes and satisfaction in telemedicine is expanding rapidly, far less is known about how telemedicine affects physicians themselves—particularly regarding work-life balance, professional satisfaction, and mental health. Understanding these associations is essential as telemedicine becomes a more established mode of clinical practice.

Objectives: The primary objective of this study was to evaluate physician well-being within a telemedical practice environment.

Methods: This study presents findings from a cross-sectional survey conducted among physicians working in a telemedical center in Switzerland. The survey included 42 validated questions assessing work-life balance, professional satisfaction, emotional exhaustion, and symptoms of depression. Data were collected between June and August 2023. Participation was voluntary, anonymous, and open to all physicians practicing telemedicine at the center.

Results: A total of 49 physicians completed the questionnaire. The majority were female (73.5%), and most had children (71.4%). More than 90% of respondents reported experiencing a good work-life balance while working in telemedicine. High emotional exhaustion was identified in 12.5% of participants, while 16.32% screened positive for possible depression.

Discussion: These results suggest that practicing telemedicine may support a favorable work-life balance for many physicians and could potentially mitigate some aspects of burnout. However, the presence of emotional exhaustion and depressive symptoms in a subset of participants highlights the need for continued attention to physician well-being in digital care settings. As telemedicine continues to expand, further research—particularly longitudinal studies—is needed to better understand its long-term impact on physicians' mental health and to identify organizational factors that promote sustainable and healthy telemedicine practice.

Conclusion: Telemedicine appears to support a favorable work-life balance for many physicians and may help reduce aspects of burnout.

Context: 在中国，2型糖尿病（T2DM）的患病率持续上升。社区糖尿病服务与T2DM患者的需求之间仍然存在差距。了解服务利用的多层次决定因素对于改善社区慢性病管理至关重要。T2DM在中国的患病率持续上升，使其成为一项重要的公共卫生慢性疾病。尽管中国基层医疗卫生体系不断扩展，但社区糖尿病服务与T2DM患者的需求之间仍然存在差距。了解服务利用的多层次决定因素对于改善社区慢性病管理至关重要。

Objectives: 本研究探讨了影响社区 T2DM 管理的患者、家庭和系统层面的因素，并运用安德森健康服务利用行为模型（安德森行为模型）来检验易感因素、促成因素和需求决定因素。

Methods:本研究在XXX的三个社区卫生服务中心开展了一项定性研究。研究人员对25名社区管理的2型糖尿病患者和11名全科医生进行了半结构式访谈。数据分析采用Colaizzi的七步法，并将主题映射到Andersen的行为模型上。

Results: 研究结果归纳出三大主题类别。易感因素包括自我管理信念薄弱、糖尿病知识有限以及家庭在情感和信息方面的支持不足。促成因素包括已建立但利用不均衡的社区服务，例如签约管理、三级预防和专科诊所，以及主动服务提供、家庭参与、全科医生培训和医护人员支持方面的不足。需求因素反映出患者对疾病相关知识的强烈需求，但同时对并发症筛查的认知度较低，且对个性化、持续性和可及性的医疗服务的期望未能得到满足。

Discussion: 总体而言，这项研究揭示了患者需求与社区糖尿病服务能力之间持续存在的不匹配。应对这些挑战需要采取协调一致、以患者为中心的策略，加强健康素养、家庭参与和全科医生的能力，以提高社区2型糖尿病管理的连续性和有效性。

Conclusion: 患者需求与现有社区糖尿病服务能力之间仍存在显著差距。加强健康素养、家庭参与、全科医生能力以及系统层面的支持，对于提高社区2型糖尿病管理的连续性和有效性至关重要。这些发现为以患者为中心、以系统为导向的基层医疗改革提供了实证依据

Context: Saarland-University coordinates a project bringing together 15 universities across Germany. Students in their final year choosing general practice (GP) rotation are disadvantaged due to missing affiliation to university onsite teaching. Resources in teaching small numbers of students are limited, due to resource constraints. We developed PJ-Teaching, an inter-university online seminar series. This supplements local teaching, ensures longitudinal learning regardless of location, and enables universities to share high-quality sessions—reducing workload while enriching the curriculum. With our workshop we want to extrapolate to a greater context. Due to a comparable structure of medical education, time and geographical difference, we intend to develop the project within Europe to facilitate undergraduate engagement.

Objectives: We want to connect teachers and learners, who face similar limitations and hereby pool expertise in practical year teaching. There are many other innovative projects in collaborative teaching which can share their experience, chances and limitations. Main objective is to create a space where international teaching projects can be designed and implemented, alongside with the YDM movement.

Teaching method and workshop: We will introduce a structured, decentralized, online collaborative model that connects institutions and students. Open brainstorming will initiate an international branch of final year undergraduate collaborative online education. 0010min: Introduction 1

Expected outcomes: Develop a student-centred cross-border teaching project: We aim a total of 5-10 online seminaries for 2027 held by different countries (English). Seminars will align in structure; however, we want to ensure an individual site/country-specific approach to

Conclusion: The ongoing struggle to encourage young students to choose general practise ought to start in medical education, by bringing them closer to FM during the final year of undergraduate training. Sharing practical insight among educators is important. Through collaboration in joint teaching events, a network emerges that can also be utilized to improve teaching sustainably.

Context: Chronic brucellosis is a zoonosis where symptoms (fever, sweating, myalgia, arthralgia) can persist for months or years

Methods: A 66-year-old woman employed as healthcare assistant in the local GP Practice, but also working part time in a family meat processing business, presented with severe bone pain, localized mostly in the sacroiliac area and lumbar spine, greatly restricting her mobility. She was previously seen by an orthopedic surgeon who prescribed treatment with NSAIDs, which however did not improve her symptoms. She was reviewed by the duty general practitioner, who in light of the occupational hazard from the meat processing business and the raised inflammatory markers recommended screening for chronic brucellosis, as well.

Originality: The Brucella IGG & IGM antibodies were negative, however, her son, who was working in the local veterinarian laboratory took a blood sample from his mother, and run a Rose Bengal test which returned s strong positive result.

Lessons learned and future implications: The patient was hospitalized and received treatment for 3 months for chronic brucellosis. She improved significantly and regained her mobility

Discussion: The prozone phenomenon where too many antibodies overwhelm the bacteria,

preventing them from effectively agglomerating, leading to a negative result is the most likely explanation for the false positive result of the test. To avoid this, it is recommended to dilute the serum to high dilutions (1/640) or to perform an indirect Coombs test or Brucellacapt test (specific for patients with chronic disease) or PCR.

Conclusion: The family physician should be aware of this possibility when examining patients with an increased probability of Brucellosis.

ID 1264- Development of a care guide for people with hypertension and type 2 diabetes for interprofessional primary health care teams

Luis Manuel CABRERA LIBRERO

Hospital Virgen De Altagracia, Manzanares, Espagne

Context: Dans le cadre rigide des Soins de Santé Primaires (SSP), Elena, veuve de 65 ans atteinte de diabète de type 2 et de dépression réactionnelle, fait l'expérience d'un échec thérapeutique. Le conflit émerge entre un protocole « algorithmique » de 10 minutes et une patiente qui se sent réduite à une valeur glycémique, ce qui conduit à l'abandon du traitement et à une perte de confiance.

Methods: L'intervention se déplace de l'imposition technique vers la dissidence professionnelle. Les méthodes ont inclus : Autonomie clinique : allongement du temps de consultation afin d'aborder le deuil. Prise en charge avec une approche d'équité : coordination d'un soutien social communautaire plutôt que des conseils diététiques génériques. Alliance horizontale : remplacement du paternalisme par une vulnérabilité partagée et une écoute « fraternelle ».

Originality: Alors que la « non-observance » est largement documentée, ce cas est original dans sa formulation de la « Désobéissance Thérapeutique » comme un devoir éthique professionnel. Il existe peu de rapports qui qualifient explicitement la résistance aux indicateurs administratifs de « force » clinique plutôt que d'infraction

Lessons learned and future implications: Le cas enseigne que le succès clinique (contrôle de l'HbA1c) est souvent un sous-produit de la validation émotionnelle. Toutefois, il met en garde : les professionnels doivent équilibrer la « désobéissance » avec la sécurité médico-légale et administrative afin d'éviter des sanctions institutionnelles tout en protégeant le patient.

Discussion: Forces : Ce cas montre que la relation médecin-patient constitue un outil thérapeutique puissant. Il aborde les déterminants sociaux (deuil, solitude) comme la racine des marqueurs biologiques. Limites : Ce modèle est difficilement généralisable dans des systèmes de santé obsédés par la productivité. Il existe un risque d'épuisement professionnel lié à une « éthique de la résistance » face aux pressions administratives

Conclusion: Le rétablissement d'Elena démontre que la médecine est la « science du sujet ». La véritable maîtrise en soins de santé primaires réside dans la capacité à traduire les recommandations scientifiques dans le langage de la justice sociale et de la dignité humaine.

(2) University Of Medicine And Pharmacy Of Craiova, Craiova, Roumanie

Context: Celiac disease (CD) is a frequent immune-mediated disorder, yet its diagnosis in adults remains challenging due to heterogeneous and often extra-intestinal presentations. In primary care, patients may present with non-specific symptoms, leading to diagnostic delay and prolonged morbidity.

Methods: We report three adult female patients (aged 31, 27 and 38 years) presenting to primary care over a two-year period with atypical manifestations ultimately diagnosed as CD. The first patient presented with purpuric lesions of the lower limbs and intermittent polyarthralgia, without gastrointestinal symptoms. Laboratory evaluation revealed normocytic anemia and iron deficiency. Skin biopsy showed neutrophilic dermatosis. Positive celiac serology (anti-tTG IgA, anti-endomysial and anti-gliadin antibodies) led to upper endoscopy, which confirmed villous atrophy. The second patient complained of chronic asthenia and diffuse myalgia. Biological assessment identified persistent vitamin D deficiency despite prolonged supplementation, with otherwise normal findings. Anti-tTG IgA and anti-endomysial IgA antibodies were positive, and duodenal biopsy confirmed villous atrophy. The third patient presented with progressive fatigue, mucocutaneous pallor, headaches, bloating and occasional epigastric pain, significantly affecting daily functioning. Laboratory tests showed moderate hypochromic microcytic anemia with severe iron deficiency. Celiac serology was strongly positive for multiple antibodies, and histology confirmed villous atrophy. In all cases, diagnostic pathways were initiated in primary care and coordinated with gastroenterology. A limitation was the absence of standardized screening criteria for atypical presentations.

Originality: These cases illustrate uncommon adult presentations of CD, including dermatological, rheumatological and isolated nutritional deficiency manifestations. While such presentations are individually reported, their identification in primary care highlights the need for increased diagnostic vigilance beyond classical gastrointestinal symptoms.

Lessons learned and future implications: CD should be considered in patients with unexplained anemia, persistent vitamin deficiencies or systemic symptoms. Lower thresholds for serological testing in primary care may reduce diagnostic delays.

Discussion: The variability of adult celiac disease challenges traditional symptom-based diagnostic approaches. Primary care plays a crucial role in early recognition, particularly when presentations are subtle or extra-intestinal.

Conclusion: A high index of suspicion for celiac disease in primary care, even in the absence of gastrointestinal symptoms, can lead to timely diagnosis and improved patient outcomes. These cases support a more proactive diagnostic approach to atypical presentations.

Context: Spontaneous pharyngeal perforation is a rare condition with nonspecific symptoms that can mimic more common airway or esophageal disorders. Limited clinical awareness may delay diagnosis, increasing the risk of complications. This case describes an unusual pharyngeal rupture triggered by suppressed sneezing.

Methods: A 41-year-old man presented to the Emergency Department with hoarseness, odynophagia and dyspnea following multiple episodes of suppressed sneezing. Several hours later, the patient developed anterior neck pain and bilateral cervical swelling, following forced body position leaning forward, because of dyspnea. There was no history of trauma or predisposing factors. Physical examination revealed bilateral neck swelling with subcutaneous emphysema. Fiberoptic examination showed mild larynx edema and hemorrhage of the right vocal fold. Laboratory tests were unremarkable. Computed tomography of the neck and chest, along with esophageal fluoroscopy, showed subcutaneous emphysema involving the neck, face and pneumomediastinum and a suspected defect above the left margin of the epiglottis.The patient was admitted to thoracic surgery department for observation and managed conservatively with analgesia, intravenous

amoxicillin/clavulanate, fluid therapy, and stress ulcer prophylaxis. Follow-up chest radiography showed no progression of emphysema, with well-aerated lungs. Symptoms resolved progressively, and the patient was discharged after four days. Strengths of management included early imaging and multidisciplinary involvement. Limitations were the inability to directly visualize the perforation and the absence of long-term follow-up data.

Originality: Pharyngeal perforation is more commonly associated with trauma, instrumentation, or severe vomiting. Cases related to suppressed sneezing are rare, with only limited reports in the literature. This case highlights a low-energy, self-induced mechanism leading to clinically significant injury.

Lessons learned and future implications: This experience underscores the need for clinical vigilance when evaluating acute cervical emphysema without trauma. Early imaging and interdisciplinary communication are critical. Conservative management may be sufficient in stable patients, but careful monitoring is essential.

Discussion: The case illustrates how subtle symptoms can conceal rare but potentially serious pathology. Coordinated care among primary care physicians, ENT doctors, radiologists and thoracic surgeons enabled timely diagnosis and safe management.

Conclusion: This case broadens awareness of spontaneous pharyngeal perforation as a possible consequence of suppressed sneezing and highlights the importance of multidisciplinary collaboration to ensure prompt diagnosis and favorable outcomes.

ID 330- Development of machine learning-based mortality prediction models in older adults using routine primary care data: Comparing overall performance with a dementia subgroup

Enmanuel CHIRINO, Eva DE LA TORRE BUEDO

20885, Madrid, Espagne

Context: Superficial venous thrombosis (SVT) is a frequent condition in primary care and is often considered benign. However, certain clinical and anatomical characteristics may increase the risk of progression or extension to the deep venous system, influencing therapeutic management. The integration of clinical ultrasound into the daily practice of family physicians enhances clinical autonomy, decision-making capacity, and patient safety.

Objectives: A 62-year-old woman with no relevant past medical history presented to primary care with one month of left calf pain associated with swelling, episodic erythema, and local warmth, with recent worsening and functional limitation for walking. Physical examination revealed multiple varicose veins and painful palpable cords along the superficial venous trajectory, without systemic symptoms.

Methods: Given the persistence and progression of symptoms, a venous clinical ultrasound was performed in the primary care consultation. The examination showed a non-compressible superficial vein with absent Doppler flow, consistent with superficial venous thrombosis of the great saphenous vein, with an estimated extension of 7–10 cm and no involvement of the saphenofemoral junction. Deep vein thrombosis was excluded. Based on these findings, the family physician decided immediate referral to the emergency department for diagnostic confirmation and management. In the emergency setting, a markedly elevated D-dimer level (>3000 ng/mL) was detected, and Doppler ultrasound confirmed the diagnosis. Anticoagulant treatment with fondaparinux was initiated.

Results: This case illustrates the active diagnostic and decision-making role of the family physician using clinical ultrasound. Rather than serving as a purely descriptive tool, ultrasound directly influenced risk stratification, therapeutic decisions, and referral timing, reinforcing the central role of family medicine in vascular care.

Discussion: Superficial venous thrombosis should not be systematically considered a benign condition. Clinical ultrasound in primary

care enables early identification of higher-risk SVT, supports evidence-based management, and reduces diagnostic delays. Its routine use strengthens continuity of care and improves patient safety.

Conclusion: Clinical ultrasound empowers family physicians to play a leading role in the diagnosis and management of superficial venous thrombosis, confirming its value as an essential tool in modern primary care practice.

Context: In an era of rising physician burnout, this workshop addresses the critical need for family physicians to cultivate professional resilience and personal well-being. It reframes "personal branding" from a marketing concept into a transformative tool for achieving professional authenticity. By guiding physicians to consciously define and project their genuine identity, the workshop provides a method to align their careers with their core values, fostering greater leadership, satisfaction, and a powerful antidote to burnout.

Objectives: 1. Define an authentic personal brand that aligns professional goals with personal well-being. 2. Articulate this brand through a compelling mission statement and elevator pitch. 3. Apply branding strategies to build a professional network and enhance their digital presence.

Teaching method and workshop: 0-10 min: Introduction to the concept and purpose of personal branding for physician authenticity and wellness. 10-30 min: Interactive exercises in pairs and small groups to guide participants in defining their brand, crafting a mission statement, and

Expected outcomes: Participants will leave the workshop equipped with a clear framework for articulating their authentic professional narrative and a set of actionable strategies. Tangible outcomes include a drafted personal mission statement, a tailored elevator pitch, and

Conclusion: "The Authentic Physician" empowers family physicians by bridging the gap between professional identity and personal well-being. It provides the practical tools needed to build a brand that not only enhances career opportunities and leadership presence but also serves as a foundational element of authenticity and resilience. This workshop equips physicians to navigate the complexities of modern healthcare with a renewed sense of purpose and control over their professional journey.

ID 1767- Diabetes Mellitus and Vulvovaginal Disorders

Aouayeb KHADIJA

Medical Resident, Nabeul, Tunisie

Context: Acute pain represents a challenge for the emergency physician, due to its prevalence and clinical implications. Paracetamol, widely used for moderate pain, is often administered parenterally, long considered more effective. However, recent studies have shown that it is not superior to the oral route, in terms of efficacy and rapidity of action.

Objectives: Our aim was to compare the two routes of paracetamol administration in the management of moderate acute pain in emergency setting.

Methods: This was a prospective, interventional, randomized, single-center study conducted over a six-month period,enrolling patients aged 18 and over, consulting for moderate acute pain in the emergency department of Taher Maamouri Hospital of Nabeul.After consent, participants were randomized into two groups: IV (1 g paracetamol infusion) and PO (1 gparacetamol effervescent). The primary endpoint was a VAS

≤ 3 at 30 minutes in each group. Secondary endpoints were safety and use of rescue analgesia.

Results: One hundred and fifty patients were included (IV: n=75; PO: n =75) with a gender ratio of 1.3 and a mean age of 50±19 years. Mean VAS at T0 was 4.71±0.6 cm with no significant difference (p=0.591). A VAS ≤3 at T30 was obtained in 45 patients in the IV group and 44 patients in the PO group, with p=0.868. There was no significant difference between the two groups in the difference in mean VAS, and in the significant decrease of 10 mm at T30. Sixty-one patients required rescue analgesia at T30, with no difference between the 2 groups (p=0.868). No major adverse events were noted. Minor adverse events were comparable between the two groups at T30 and T60. Six patients in the IV group had an injection-site complication.

Discussion: Clinical and hemodynamic parameters, pain reduction, and need for rescue analgesia were comparable between oral and IV paracetamol. Oral administration avoids injection-related discomfort, with similar safety and efficacy, supporting its use as a practical alternative for moderate acute pain in emergency settings.

Conclusion: Our study showed that oral paracetamol was non-inferior to injectable paracetamol in the treatment of moderate acute pain in emergency departments. Further randomized, double-blind studies are needed to validate our results.

ID 180- Diagnosis and Management of Classic Trigeminal Neuralgia in a Primary Care Setting: Importance of Clinical Reasoning and Interprofessional Collaboration

Fernanda KIMURA [1] , Matheus GÓRIOS [2], Caio SILVA [2], Osmar PERSON [2], Carlos GÓRIOS [2], Marcela PANDOLFI [2], Luciane PEREIRA [2], Cleo CHINAIA [3], Samatha VALENCIO [2], Cintia RODRIGUES [2]

(1) Unisa, Embu-Guaçu Sp, Brésil
(2) Universidade São Camilo, São Paulo, Brésil
(3) Unisa, São Paulo, Brésil

Context: Throughout history, numerous conflicts and wars have resulted in the forced migration of populations. Refugees require special attention regarding their health, as their condition is often characterized by physical and emotional hardships stemming from traumatic experiences, family separation, challenges during displacement, language barriers, and the need for cultural sensitivity, among other factors. For medical education to effectively address the care of women and the challenges they face in refugee situations, it is essential to understand the social contexts in which they are embedded. These women may be living in a new country without a partner, facing economic hardship, and belonging to an ethnic minority. Such conditions often overlap with the demands of motherhood, resulting in a situation of multiple vulnerabilities.

Objectives: To describe the maternal characteristics of refugee women who gave birth in the city of São Paulo, Brazil, based on data from the Birth Information System (2011–2024).

Methods: This was a descriptive cross-sectional study based on data from the Live Birth Information System (SINASC) of the city of São Paulo, Brazil, covering the period from January 2011 to December 2024.

Results: Preliminary findings indicated that births to immigrant women in the city of São Paulo accounted for 3.1% of all registered births. Regarding race/skin color, 46.6% were Black or Brown women, primarily from African countries, followed by those from Latin American nations. Among the women who gave birth, 8.0% were adolescents (≤19 years), and 4.4% had high-risk pregnancies (≥40 years). Additionally, 26.5% had an insufficient number of prenatal visits (≤7 consultations), 36.8% delivered by cesarean section, and 34.3% reported having no partner.

Discussion: It is essential to promote continuing education in health for professionals, including physicians, that addresses refugee health and prepares them to work within a model of cultural competence. Such training should foster a set of attitudes

and communication skills that enable professionals to interact effectively within the cultural contexts of their patients.

Conclusion: This study highlights opportunities for improving prenatal care so that, in addition to obstetric evaluation, women receive guidance on gestational changes, self-care, newborn care, and their rights throughout the childbirth process.

Fernanda KIMURA [(1)] , Matheus GÓRIOS [(2)], Caio SILVA [(2)], Osmar PERSON [(2)], Carlos GÓRIOS [(2)], Marcela PANDOLFI [(2)], Luciane PEREIRA [(2)], Cleo CHINAIA [(1)], Samatha VALENCIO [(2)], Cintia RODRIGUES [(2)]

(1) Unisa, Embu-Guaçu Sp, Brésil
(2) Universidade São Camilo, São Paulo, Brésil

Context: In Brazil, the expansion of higher education in recent decades has occurred within a context of significant privatization, particularly in medical programs, which have historically been accessed mainly by students from privileged social backgrounds. Integrating medical students into the Unified Health System (SUS) promotes training aligned with humanization and comprehensive care, fostering closer connections between medical practice and community needs. Violence driven by gender inequality, racism, xenophobia, and other forms of intolerance has profound health impacts and reveals important gaps in medical education, especially regarding the preparation of future physicians to address situations of social vulnerability.

Objectives: To describe reported cases of violence motivated by gender, racism, xenophobia, and other minority-related issues in the city of São Paulo in 2022, and to discuss their implications for undergraduate medical education.

Methods: This cross-sectional, descriptive, and retrospective study analyzed data from the Information System for Violence and Accident Surveillance (SIVVA) of the São Paulo Municipal Health Department. A total of 11,643 reported cases of violence involving city residents were included. Cases were categorized according to the motivation for violence, victim life stage and sex, characteristics of the violent act, relationship to the perpetrator, and perpetrator sex.

Results: Among reported motivations, sexism accounted for 51% of cases, followed by homophobia/lesbophobia/transphobia (3.3%), racism (0.7%), and xenophobia (0.3%). Most victims were adults (59.2%), followed by adolescents (22%) and children (11.9%). Violence was predominantly perpetrated by third parties (88.9%), with male aggressors responsible for most cases (75.2%). Recurrent episodes of violence were identified in 44.5% of reports.

Discussion: The findings highlight the need for medical education to incorporate a critical approach to social determinants of health, cultural diversity, and vulnerability. Exposure to real-world contexts of violence, particularly within primary health care settings, supports the development of reflective and socially responsive physicians capable of addressing complex care demands beyond a strictly biomedical perspective.

Conclusion: The analysis of violence motivated by gender, racism, and xenophobia reinforces the importance of integrating discussions on social inequalities and vulnerability into medical training. This approach promotes cultural competence, humanized care, and greater preparedness to manage violence-related situations in clinical practice.

ID 1354- Diagnostic Challenges and Comprehensive Management of Pulmonary Disease Caused by Mycobacterium avium Complex in an Immunocompetent Patient

Tochi IROKU-MALIZE, Amanda INGA-O'CONNELL, Aldo ALLEVA, Barbara KEBER, Sara SIDDIQUI

Northwell, New York, États-Unis

Context: Traditional precepting models in medical education face challenges in providing flexible supervision and expanding learning opportunities, particularly in resource-constrained environments like student-run free clinics (SRFCs). This quality improvement project evaluated a novel hybrid precepting model within an SRFC in Queens, NY, where medical students delivered in-person patient care while attending physicians alternated between in-person and telehealth supervision. The aim was to enhance both student learning and community health service access.

Methods: Utilizing a qualitative approach, data was gathered through surveys and focus groups involving medical students and preceptor physicians. The study explored perceived benefits and challenges associated with combining in-person clinical experience for students with flexible, hybrid physician supervision.

Originality: This study offers unique insights into the implementation and evaluation of a hybrid precepting model, specifically in an SRFC setting. It addresses the growing need for adaptable educational strategies in undergraduate medical education that leverage telehealth technologies, simultaneously contributing to effective student supervision and expanding community health service provision within the evolving digital healthcare landscape.

Lessons learned and future implications: Findings revealed high student satisfaction with both in-person and virtual precepting, noting comparable learning outcomes. Critically, virtual precepting fostered unexpected benefits, including enhanced peer learning, development of skills crucial for residency (e.g., adaptability, resourcefulness), and increased student leadership and accountability. These insights highlight latent but significant considerations for contemporary student supervision models. The hybrid approach demonstrates potential to increase preceptor volunteer hours without compromising care integrity or educational quality.

Discussion: The hybrid model delivered comparable learning outcomes and high student satisfaction. Virtual precepting uniquely fostered enhanced peer learning, crucial residency skill development, and greater student leadership. This effective approach grants preceptor flexibility, enriches education, and maintains patient care quality within SRFCs.

Conclusion: This hybrid precepting model, successfully combining in-person and virtual supervision, demonstrates its capability to deliver robust learning outcomes and maintain high student satisfaction. It offers a flexible and effective solution for medical education, particularly in SRFCs, fostering novel skill development and potentially increasing preceptor engagement. This innovative approach warrants further investigation and broader consideration for implementation within undergraduate medical education to adapt to and leverage the evolving digital healthcare landscape.

Context: Primary care teams across Europe are adapting to increasing complexity and workforce shortages. This evolution calls for new roles for non-physician professionals, such as nurses, to strengthen continuity and patient-centered care. Implementing these roles requires evidence-based strategies and practical tools. This workshop brings together insights from three research projects that explore how role transformation can be successfully achieved in general practice.

Objectives: Understand diverse approaches to introducing new roles for non-physicians in primary care teams. Identify barriers and

enablers for sustainable role integration. Apply a practical tool to assess readiness for change in participants' own context.

Teaching method and workshop: The session combines concise presentations with interactive exercises. Each presenter will share findings from their project, followed by group work using a validated tool to reflect on applicability in different settings. Introduction (5 min): Overview

Expected outcomes: Participants will gain evidence-based insights and practical tools to guide role transformation in primary care, leaving with actionable strategies tailored to their own practice environment.

Conclusion: Redefining roles for non-physician professionals is essential for sustainable primary care. By combining research findings with hands-on exercises, this workshop empowers teams to embrace change effectively.

Context: Both air pollution and genetic factors independently influence the development of COPD. However, few studies focus on gene and air pollution synergic interaction in COPD.

Objectives: We assessed the independent and synergic effects between susceptibility genes, PM2.5 and other air pollutants and COPD.

Methods: We assessed the independent and synergic effects between susceptibility genes, Particulate Matter 2.5(PM2.5) and other air pollutants and COPD. We collected 21,255 participants from Taiwan Biobank with health, lifestyle, and gene data. Air pollution exposure was estimated aerosol optical(AOD-PM2.5) prediction method for PM2.5 concentration prediction and inverse distance weighting (IDW) method to evaluate other pollutants (O3, NO2, CO, SO2). Genome-wide single nucleotide polymorphism(SNP) genotyping related to COPD with pint<1 × 10−6 and gene—environment interaction was test by "adaptive combination of Bayes factors method" (ADABF) method.

Results: In our study, the participants exposure to PM2.5 concentration more than 22.45μg/m3 was significantly associated with COPD (OR=1.599 (95% CI=1.181- 2.165)) after multivariate adjustments. There were 87 SNPs reach significant level. Eleven SNPs of 87 revealed the relationship between NO2 and COPD interaction. SCMH1 (Scm Polycomb Group Protein Homolog 1) on chromosome 1, WDPCP (WD Repeat Containing Planar Cell Polarity Effector) on on chromosome 1, TESC-AS1 (TESC antisense RNA 1) on Chromosome 12, five SNPs on chromosome 5, two SNPs on Chromosome 9 and one SNPs on chromosome 20 showed the gene-environment interaction in COPD cases.

Discussion: Our study identified a positive association between PM2.5 exposure and COPD risk, with eleven SNPs showing interactions with NO_2. Prior Asian studies reported TP63 rs4488809 interacting with non-small cell lung cancer (NSCLC) and positive association of PM2.5 and COPD. Variations in pollutant composition and exposure levels may influence results. As a cross-sectional study, causal relationships between PM2.5, genetic susceptibility, and COPD could not be definitively established.

Conclusion: Long-term PM2.5 exposure was associated with increased COPD risk, and synergistic effects between genetic factors and NO_2 were observed. Further prospective cohort studies are warranted to validate these findings

ID 350- Digital health and hypertension management: primary care professionals' perceptions of institutional digital tools

Yuval SHACHAF, Amit GIBORI, Zada LIOR, Hanny YESHUA

The Department Of Family Medicine, Tel-Aviv District, Clalit Health Services, Israel, Tel Aviv, Israël

Context: Primary-care clinicians frequently use structured assessments across multiple domains, including mental health, pain, frailty, and medication reviews, as well as core Lifestyle Medicine domains such as physical activity, nutrition, sleep, stress management, and health behavior change. Many patients experience difficulty understanding technical wording or expressing concerns directly, especially when linguistic or cultural differences shape communication. These barriers may reduce diagnostic precision and limit the effectiveness of routine assessments. Recent advances in open-source large language models (LLMs) allow clinicians to design their own personalized chatbots that support clearer real-time communication, simplify complex phrasing, and adapt questions to patient needs. Importantly, such tools can be developed for any clinical topic chosen by the clinician, while fully preserving clinical judgment and professional autonomy. This workshop offers a practical and safe framework for building a functional chatbot tailored to clinical practice.

Objectives: The workshop will enable participants to: -Learn the core principles for designing clinician-directed LLM chatbots for diverse clinical purposes. -Convert structured clinical tools into patient-oriented conversational flows. -Build a working chatbot prototype for a self-selected clinical domain. -Apply safety, transparency, and ethical guidelines to ensure responsible AI use during consultations. - Adapt chatbot behavior for multilingual and multicultural patient populations.

Teaching method and workshop: The workshop includes live demonstrations, guided hands-on chatbot building, and small group design exercises. The session will provide templates, safety guidance, and examples illustrating chatbot-driven communication. Sessions will also highlight common

Expected outcomes: Participants will leave with a customizable chatbot prototype and a replicable framework for developing additional tools in their clinical setting.

Conclusion: Clinician-designed chatbots built on open-source LLMs can improve diagnostic clarity, bridge communication gaps, and enhance patient engagement across a wide range of primary-care domains. This workshop equips clinicians with practical skills to create safe, personalized AI tools that support real-time communication and informed decision-making.

ID 2046- Digital Twins in Primary Care: From Concept to Clinic

Eda YALDIRAK

Acibadem Mehmet Ali Aydinlar Unversity, Istanbul, Türkiye

Context: Digital information-seeking behavior has emerged as a potential proxy for awareness and engagement with health services. Google Trends provides anonymized, real-time data that may reflect public interest in diseases and preventive services. However, how these digital signals relate to cancer burden across different socioeconomic contexts remains insufficiently explored.

Objectives: To assess the ecological association between online search interest for selected cancers and screening tests and corresponding cancer incidence and mortality across Human Development Index (HDI) groups.

Methods: An ecological study was conducted including 185 countries, classified into four HDI groups (low, medium, high, very high). Google Trends relative search volumes (RSV) were retrieved for terms related to breast, prostate, colorectal, and cervical cancers, and associated screening tests (mammography, prostate-specific antigen, colonoscopy, Pap smear, and human papillomavirus). Additional analyses included stomach, pancreatic, lung, and liver

cancers, for which no established population screening programs exist. Spearman correlation coefficients were calculated to examine relationships between RSV values and cancer incidence and mortality rates.

Results: Screening-related searches demonstrated stronger positive correlations with incidence and mortality in higher HDI countries. Cervical cancer–related searches showed positive correlations with disease burden in high and medium HDI groups, while significant associations persisted for cervical cancer in low HDI countries. Cancers without established screening programs generally showed no correlations with epidemiological indicators, except for modest associations in very high HDI countries and moderate correlations for liver cancer in low HDI settings. Increasing HDI was associated with higher burdens of colorectal, breast, pancreatic, and lung cancers, whereas inverse patterns were observed for cervical and liver cancers.

Discussion: Online information-seeking behavior shows context-dependent associations with cancer epidemiology. However the findings suggest that digital search behavior reflects not only disease burden but also screening availability, health literacy, and access to care. Stronger correlations in high HDI settings likely reflect institutionalized screening programs, while persistent cervical cancer correlations in lower HDI countries may indicate unmet preventive needs, particularly among socioeconomically disadvantaged women.

Conclusion: Google Trends may serve as a complementary digital indicator to inform public health surveillance and primary care–oriented cancer prevention strategies when interpreted within socioeconomic frameworks.

ID 1969- DISCUSS – A Secure HER-integrated Inpatient Proxy Messaging: Baseline Perceptions and Ongoing Mixed-Method Evaluation

Marc BESNIER

Poitiers, Poitiers, France

Context: CBD is experiencing massive growth in current consumption. It is used during pregnancy to manage pain, anxiety, and sleep disorders. It is estimated that 20% of women in certain populations consume it at least once. Sometimes it replaces THC, which is known to have effects on pregnancy and fetal development. CBD may contain significant levels of THC, which could already have an impact.

Objectives: Does CBD have the same effects as THC on pregnancy and fetal development?

Methods: Systematic review of the literature in accordance with PRISMA criteria. Declaration made to Prospero in 2023. Blind collection by two investigators using RAYYAN software. Search of PubMed, Lissa, Psychinfo, Embase, Cochrane, and Google Scholar databases for gray literature.

Results: 112 references analyzed, 6 studies selected with 7 additional in vitro studies for further analysis. Four ex vivo case-control studies and two descriptive epidemiological studies The studies show that CBD consumption during pregnancy has an impact on the fetus, with an increased risk to fetal development, particularly through an increase in congenital and hormonal abnormalities during life in utero, as well as an increased risk of gonadal and tumor abnormalities in the long term. CBD has been shown to alter the placental barrier, increasing the fetus's exposure to harmful substances.

Discussion: There is a risk of fetal pathology associated with CBD use. Complications during pregnancy are also reported in the studies reviewed. These risks are significant, especially given the increase in consumption. Women are rarely asked about their consumption habits. Conducting research to better understand the concerns of pregnant women and their needs would be a first step toward improving care and reducing consumption. Systematizing our questions would also allow us to better understand consumption and conduct more robust studies on the effects on pregnancy and fetal development. Strength: first systematic review of the literature on the subject, exhaustive, conducted blind by two reviewers

Weakness: low quality of studies, low recruitment

Conclusion: The general practitioner plays a central role in preventing this risk to pregnancy and the fetus, and we must take advantage of this to avoid the consequences.

(3) National University Hospital, Singapore, Singapore, Singapour

Context: Diabetes and prediabetes are prevalent chronic conditions that remain substantially underdiagnosed, particularly among populations with limited preventive healthcare engagement. Reliance on self-reported health status and previously known diagnoses therefore underestimates the true burden of glycaemic abnormalities within communities. Socioeconomically-vulnerable groups, including residents of public rental-housing, are at higher risk of missed screening and delayed linkage to primary care services.

Objectives: Community-based health-screening programmes provide a valuable platform to identify incidental glycaemic abnormalities and reveal gaps in primary care engagement. This study aimed to quantify the burden of incidentally detected glycaemic abnormalities in a socioeconomically-vulnerable population and to examine associations with primary care engagement.

Methods: This cross-sectional study included 68 adult patients ≥40 years who participated in a health-screening programme conducted in a rental-housing estate with socioeconomically vulnerable residents. HbA1c testing was performed. Glycaemic status was classified using standard HbA1C criteria. Logistic regression was used to explore associations between incidental glycaemic abnormalities, prior screening history, and enrolment with GP clinics under HealthierSG, a national healthcare initiative.

Results: Mean age of participants was 62.3 years [±10.4], with equal sex distribution. Participants were predominantly Chinese[55.9%], followed by Malay[23.5%], Indian[11.8%], and other ethnicities[8.8%]. 38.2% of participants reported having at least one chronic condition [hypertension, diabetes, or hyperlipidaemia]. Most participants were not enrolled in HealthierSG [67.6%], and 47.1% had not received any health-screening in the last year. Mean HbA1c was 5.92% [±0.96]. 35.3% [24/68] had prediabetes, 19.1% [13/68] had diabetes, and 45.6% [31/68] were normoglycaemic. 84.6% of diabetes cases occurred in participants without prior diabetes diagnosis. Screening within the past year was not significantly associated with incidental glycaemic abnormalities [prediabetes, diabetes] compared with screening more than one year ago [OR=1.05;95%CI:0.32-3.42]. HealthierSG enrolment was not significantly associated with incidental dysglycaemia [OR=0.92;95%CI:0.33-2.55].

Discussion: Community-based screenings in rental-housing populations revealed a substantial burden of previously unrecognised glycaemic abnormalities, even among individuals with recent screening or primary-care enrolment. This suggests access alone may be insufficient for effective disease detection, likely influenced by competing social priorities, health literacy and follow-up challenges in socioeconomically vulnerable populations.

Conclusion: Targeted community screening programmes may help address these gaps by enabling earlier diagnosis and improved linkage to primary care.

ID 998- Discussion of clinical cases as a methodological tool to nnhance practice: a report of teaching experience

Loïc BLANCHET-MAZUEL

Université Grenoble Alpes, Saint Genis Les Ollières, France

Context: Planetary Health focuses on the links between human activities that alter the environment and their consequences on the health of living organisms and ecosystems. Its goal is to develop solutions for a fair, sustainable and healthy world. Aware of the urgent need for action and the necessary transformation of healthcare practices, the XXX created a group dedicated to planetary health in XXX. The group, composed of around twenty general practitioners, is working on the creation of a planetary health toolkit for use by general practitioners. It is within this framework that the group is working to develop tools to support doctors in prescribing dietary advice tailored to the challenges of planetary health.

Methods: Based on the latest scientific research in global health, a summary was compiled to extract the most relevant data. Practical tools were then created for and by general practitioners. These tools, which incorporate prevention and co-benefits, can then be distributed to other doctors and passed on to patients. A poster for the waiting room and a practical information sheet have been produced and will be presented.

Originality: Combating food myths and beliefs to raise awareness of the planetary health vision by providing general practitioners with a practical tool to facilitate dietary advice. It helps to limit the burden of non-communicable diseases such as diabetes, obesity and cardiovascular disease while preserving global resources, through the prism of co-benefits.

Lessons learned and future implications: The growing interest of general practitioners in issues related to planetary health, combined with the climate emergency, highlights the need to provide support and disseminate information.

Discussion: Planetary health accompanies the transformation of general practice with a more global vision. It contributes to patient well-being and empowerment, and to the consistency of practice with global issues. Dietary advice plays an important role in planetary health, given its impact on health and the environment.

Conclusion: The dietary advice given to patients is a relevant and powerful gateway to integrating planetary health into the daily practice of general medicine, thereby enabling a form of medicine that addresses all the issues that concern it.

ID 414- Do patients experience an improvement in their quality of life after and some time following an adapted physical activity program?

Heesoo KIM, Su Hwan CHO

Department Of Family Medicine, Seoul National University Hospital, Seoul, Corée (République de)

Context: Metabolic dysfunction-associated steatotic liver disease (MASLD) has become a major global health concern, with metabolic dysfunction recognized as a key driver of hepatic steatosis. Menopause is accompanied by unfavorable metabolic changes; however, population-based evidence examining the relationship between menopausal status and steatotic liver disease (SLD) remains limited.

Objectives: To evaluate the association between menopausal status and the prevalence of SLD in middle-aged women.

Methods: Data from 15,106 women aged 40–59 years were analyzed using a nationally representative health survey (XXX). Women with a history of hysterectomy, hormone therapy use, or missing key data were excluded. SLD was defined as a hepatic steatosis index ≥36 in the presence of at least one metabolic abnormality. Menopausal status was determined by self-report. Weighted multivariable logistic regression analyses were conducted to assess the association between menopausal status and SLD, adjusting for age, body mass index, waist circumference, and major metabolic risk factors. Subgroup analyses were performed to examine potential effect modification.

Results: Overall, 31.5% of participants were postmenopausal and 22.1% had SLD. Postmenopausal women exhibited a higher prevalence of metabolic risk factors and SLD

compared with premenopausal women. After multivariable adjustment, menopause remained independently associated with SLD. The association was strongest among women aged 40–49 years.

Discussion: These findings suggest that menopausal status contributes to SLD risk beyond traditional metabolic risk factors. The stronger association observed in younger middle-aged women may reflect the metabolic impact of early estrogen deficiency during the menopausal transition.

Conclusion: Menopause is associated with an increased likelihood of steatotic liver disease in middle-aged women. Early metabolic screening and preventive interventions during the menopausal transition may be important for reducing the burden of SLD.

ID 635- Doctor, I can't measure my blood pressure in my left arm. Should I replace my device or could something else explain this?

Nuriye BAĞCI, Esra SAATÇI

Department Of Family Medicine, Faculty Of Medicine, Çukurova University, Adana, Türkiye

Context: Acute coronary syndrome (ACS) most commonly presents with chest pain; however, in elderly patients with comorbidities such as hypertension, diabetes mellitus, and hyperlipidemia, ACS may present with atypical symptoms including dizziness, fatigue, and headache. These presentations may result in delayed diagnosis and increased mortality.

Methods: A 67-year-old male presented to a family medicine clinic for prescription refills. His medical history included hypertension, diabetes mellitus, hyperlipidemia, benign prostatic hyperplasia, and generalized anxiety disorder. He reported irregular use of antihypertensive medications. The patient complained of mild dizziness, fatigue, and frontal headache lasting three days and denied chest pain, nausea, vomiting, weakness, or sensory disturbances. On examination, blood pressure was 189/96 mmHg and pulse rate was 62 beats per minute. Capillary blood glucose was 190 mg/dL, and glycated hemoglobin (HbA1c) was 7.0%. Electrocardiography showed normal sinus rhythm, and neurological examination was unremarkable. The patient was referred to the emergency department.

Originality: NSTEMI was identified in primary care despite absence of chest pain.

Lessons learned and future implications: Atypical ACS presentations are common in elderly patients and individuals with diabetes mellitus. Absence of chest pain may lead to underestimation of cardiac risk in primary care. Early recognition of atypical symptoms and timely referral are essential to prevent adverse outcomes.

Discussion: NSTEMI may present solely with mild dizziness and uncontrolled hypertension. Family physicians should maintain a high index of suspicion for ACS in high-risk patients.

Conclusion: Family physicians should recognize atypical NSTEMI presentations.

ID 222- Doctor, my neck looks dirty – a case report

Shayma ALSHEHHI, Ahmed ALHANTOOBI, Saif ALKETBI

Family Medicine Specialist At Zayed Military Hospital, Abu Dhabi, Émirats Arabes Unis

Context: Obesity is a significant global health concern with widespread implications for overall health.The UAE has a high obesity prevalence, with 43.0% of the population overweight and 32.3% obese, posing challenges to military fitness. Several studied showed high-intensity weight-loss interventions, incorporating structured dietary management and physical training have shown moderate efficacy in improving BMI in military populations. Mandatory national service military training for male UAE nationals provides a military training including intensive weight reduction program for obese recruits.

Objectives: This study examines the impact of a structured dietary and exercise intervention on BMI in obese UAE national service recruits.

Methods: A retrospective cohort study done on obese male recruits (BMI ≥30)undergoing a specific diet and intense military exercise at National services Military Camp from September 2023 to December 2023.Data of 320 recruits were collected from medical records after ethical approval.The BMI was measured in recruitment clinics before starting the intensive diet and exercise program and follow up after 4 months was done to measure the changes of BMI at the end of the course.

Results: Results indicated a statistically significant reduction in weight, decreasing from a mean of 112.22 ± 16.92 kg to 95.82 ± 13.50 kg. This amounted to an average weight loss of 16.40 kg (95% CI: 15.73–17.06, p = 0.0001, t = 48.21). Correspondingly, BMI dropped from 37.82 ± 4.99 to 32.30 ± 3.96, reflecting a mean decrease of 5.52 (95% CI: 5.30–5.74, p = 0.0001, t = 49.53).The high t-values and very low p-values indicate strong evidence that the structured diet and military training substantially improved body composition among participants. In contrast, no significant difference was observed for either systolic or diastolic blood pressure between the two time points.

Discussion: The results were encouraging, with participants losing an average of 16.4 kg and showing a clear improvement in BMI.Compared with earlier UAE studies, this program involved more participants and achieved greater results.

Conclusion: A four-month structured diet and intense military training intervention for obese UAE national service recruits significantly reduced both weight and BMI.Ongoing research should examine long-term impacts, adherence rates, and additional health outcomes to optimize these programs' benefits for recruits.

ID 1867- Doctors in Social Media – From Misinformation to Meaningful Messages

Beyzanur YAVUZ, Mustafa YAVUZ, Ayfer SAHIN

Ankara Bilkent City Hospital, Ankara, Türkiye

Context: Rabies is a fatal but preventable disease and remains endemic in Türkiye. According to the Turkish Ministry of Health, 470,918 cases of rabies-risk exposures were reported in 2024, with one confirmed case. Despite the relatively low number of cases, exposure notifications have increased annually.

Objectives: The primary objective of this study was to assess the knowledge level of family medicine residents regarding rabies and its prophylaxis. The secondary objective was to identify knowledge gaps and to highlight these areas through educational programmes aimed at improving rabies control in endemic regions.

Methods: This descriptive cross-sectional survey was conducted in September 2025 at Ankara Bilkent City Hospital. A total of 118 family medicine residents participated, including 64 contracted residents and 54 full-time residents. After obtaining informed consent, 39-item questionnaire comprising seven sections was administered through face-to-face interviews. The data were analysed using descriptive statistics. Ethical approval was obtained from the Institutional Review Board(TABED) (Approval No:2-25-1688).

Results: The overall success rate was 76.97%. Full-time residents demonstrated higher success rate (79.85%) compared to contracted residents(74.65%). The correct identification of pre-exposure vaccination schedule(days 0 and 7) was observed in 50.8% of participants, and 59.3% correctly identified that interrupted vaccination should be resumed. In fully vaccinated individuals, 75.4% correctly identified the two-dose schedule following re-exposure. Regarding adverse effects, injection-site pain and swelling were correctly identified by 92.3% of participants, whereas only 50% were aware of possible hypersensitivity reactions after repeated doses. The awareness of rabies transmission was high for dogs and cats but low for livestock and wild animals. The most common inaccurate response(68.7%)

concerned vaccination and immunoglobulin utilisation after symptom onset.

Discussion: Although fundamental rabies-risk exposure management was generally well understood, important deficiencies were identified in vaccination schedules and management after symptom onset. Limited awareness regarding transmission from rural animals may be attributable to the urban setting of the study population.

Conclusion: Despite adequate recognition of fundamental rabies exposure management, significant knowledge gaps remain regarding vaccination schedules and repeated exposure protocols. Physicians' knowledge is crucial for appropriate rabies prophylaxis and prevention of superfluous interventions. Enhancement of residency education on rabies prophylaxis may support improvement of rabies control in endemic regions.

(4) Unisa, São Paulo, Brésil

Context: Brazil is currently facing a smoking paradox, which some authors attributed to a decrease in the consumption of traditional cigarettes and an increase in the use of electronic cigarettes.

Objectives: Using data collected by COVITEL in 2022, describe the prevalence of smoking indicators and the use of electronic smoking devices among individuals residing in the Southeast region of Brazil.

Methods: Covitel is a nationwide survey representative of Brazil and the five major regions of the country: the Midwest, Northeast, North, Southeast, and South. The conclusions provide an illustration of how significant the main risk factors for Non-Transmissible Chronic Diseases (NTCDs) are in the adult population aged 18 or older

Results: Smoking was more prevalent among men and individuals aged 25 to 34 years. In terms of skin color, black or brown individuals reported a higher frequency of tobacco use. Between different education levels, those with less education (0 to 8 years) had a significantly higher frequency of tobacco use, which was three times higher than those with more education prior to the pandemic. Men, young people (18 to 24 years old), black and brown individuals, and those with higher education had a more elevated prevalence of hookah and electronic cigarette use.

Discussion: This study highlights the importance of implementing public policies that focus on improving and broadening healthcare services. It emphasizes the importance of conducting research to review tobacco control policies and initiate discussions on the regulation of electronic cigarettes.

Conclusion: Men, young people (18 to 24 years old), black and brown individuals, and those with higher education had a more elevated prevalence of hookah and electronic cigarette use.

(1) Iumfe, Geneva, Suisse
(2) Asc, Geneva, Suisse

Context: Patients with type 2 diabetes (T2D) frequently use herbal remedies, yet general practitioners' (GPs) views on such practices remain divided. Several spices and foods, such as ginger, Aloe vera, psyllium fibre, and fenugreek seeds, possess hypoglycaemic properties. Some have demonstrated effects comparable to oral hypoglycaemic drugs, but

their use for such purpose is uncommon in high income countries.

Objectives: This study aimed to explore the perspectives of GPs in a European country, regarding the use of evidence-based hypoglycaemic spices and foods in the management of patients with T2D. Specifically, it sought to describe the acceptability of recommending such products and to examine associations between GP experience and prior knowledge and acceptability.

Methods: In 2023, an anonymous 22-item questionnaire, including eight items based on the Theoretical Framework of Acceptability, was sent to all GPs in our region to explore their opinions on hypoglycaemic spices and foods and their views on recommending such dietary options to patients. Questionnaires were provided either in electronic or paper formats. Descriptive statistics were used to summarise GP responses, and logistic regression analyses were performed to examine the association between GPs' professional experience and prior knowledge of these foods, and general acceptability, adjusting for gender.

Results: A total of 207 of 570 GPs participated. While 53.1% of GPs were unfamiliar with hypoglycaemic spices and foods, most (84.3%) found their use generally acceptable, despite concerns about their efficacy (41.3%) and mechanisms of action (31.7%). Being more junior and having prior knowledge of hypoglycaemic foods was associated with higher acceptability.

Discussion: Although most GPs had no prior knowledge about the use of hypoglycaemic foods in T2D management, and some expressed concerns about their efficacy, most were willing to discuss the use of such foods with their patients, indicating a favourable attitude toward engaging with these approaches in primary care.

Conclusion: These results provide useful insights into GPs' perspectives and support the development of approaches using spices and hypoglycaemic foods in the management of T2D in European primary care, reflecting a favourable level of acceptability among GPs. Strengthening GP understanding of these interventions and confidence in their use may support their adoption in practice.

ID 1801- Drowsiness not due to Old Age or not Always Benign Hyponatremia Case of Hypopituitarism Due to a Non-Functioning Pituitary Macroadenoma

Chudi CHUKS-EBOKA, Ikponwosa MORGAN

Royal College Of General Practitioners, Hull, Royaume-Uni

Context: Primary care increasingly depends on a mobile and diverse workforce, including trainees and internationally recruited clinicians. Inconsistent onboarding and limited familiarity with local clinical workflows and digital systems can increase cognitive burden, contribute to clinician stress, and introduce patient safety risks in a new or different post. Scalable, practice-based approaches that support equitable and safe workforce integration remain limited.

Methods: We implemented an AI-enabled digital ecosystem within a UK general practice training scheme to support clinicians transitioning into new roles. The platform provided a personalised workspace integrating role-specific induction content, orientation to local digital clinical workflows, access to curated learning resources, and practical community information relevant to the clinician's location. The system functioned as an on-demand reference and orientation tool during early clinical practice and was used alongside existing induction processes. No patient data were collected or processed.

Originality: This initiative reframes onboarding as a continuous support process rather than a one-time event. By improving access to workflow-specific information and reference materials at the point of need, the model aims to reduce reliance on informal knowledge transfer and may help mitigate risks associated with unfamiliar systems, while promoting equity of experience and clinician wellbeing.

Lessons learned and future implications: Early implementation demonstrated high engagement and positive qualitative feedback,

with clinicians reporting improved readiness and confidence during transition. Key lessons included the importance of local contextualisation, role-specific design, and minimising cognitive overload. The model appears transferable to other primary care settings and healthcare systems characterised by workforce mobility

Discussion: This experience supports evidence that early-stage clinician performance and safety are influenced by system familiarity and cognitive workload. Embedding workflow orientation and reference support within a single digital environment may reduce information fragmentation and variability in induction experiences. While formal outcome data are not yet available, the approach aligns with human factors principles and workforce strategies focused on wellbeing and risk reduction.

Conclusion: An integrated, AI-enabled digital ecosystem may support safer, equitable onboarding in primary care by improving familiarity with clinical workflows and providing accessible reference support. Further evaluation is warranted to assess its impact on clinician wellbeing, patient safety, and workforce retention.

(4) University Medical Center Groningen, Department Of Primary And Long-Term Care, Groningen, Pays-Bas
(5) Maastricht University, Dept. Of Family Medicine, Caphri Institute, Maastricht, Pays-Bas

Context: Keywords: Data-driven healthcare innovation, AI, primary care Primary care is under increasing pressure due to rising workload in an ageing society, workforce shortages, and substitution of care from secondary to primary settings. Data-driven and AI tools offer strong potential to support general practitioners in administrative tasks, operational processes, and clinical decision making. However, successful implementation in daily practice remains challenging and fragmented. The Global PBRN Initiative promotes using AI in primary care data. In this workshop, we will explore the full learning healthcare systems cycle from identifying practical clinical questions, to suitable data, to validated tools and their integration back into primary care. We present and discuss five steps in a possible implementation pathway, illustrated with examples from ongoing initiatives and research experience, such as e.g. the identification of frail elderly patients in routine healthcare data. (1) Prioritize and formulate questions relevant for daily practice; (2) Collect and annotate data; (3) Develop insights and tools; (4) Iterate with end users; (5) Deliver tools via dashboards, EHR integration or software.

Objectives: 1. Identify key steps for truly engaging with as well as implementing data-driven and AI tools in general practice. 2. Recognize organizational, technical, and clinical barriers and facilitators. Participants will discuss these topics and share learnings on practical frameworks for developing, validating, and integrating tools into their own country- and contextual specific workflows.

Teaching method and workshop: We will organize an interactive workshop based on real life cases using expert inputs, consisting of presentations and discussions. Participants are invited to actively share experiences and implementation strategies. - 20 min Real-world case presentation

Expected outcomes: Through the discussions and shared learning, participants will gain a clear understanding of the key requirements for successful implementation of data-driven and AI tools in primary care, as well as their

own role within this process and practical do's a

Conclusion: Many data-driven and AI tools are rapidly emerging, but only with proper implementation, addressed in this workshop, can they provide the necessary support to daily general practice.

(2) Enf, Tarragona, Espagne

Context: Retroperitoneal masses are uncommon and clinically silent, often found incidentally. Primary Care, through physical examination and point-of-care ultrasound (POCUS), plays a crucial role in their early detection and diagnostic orientation.

Methods: A 67-year-old woman with postmenopausal bleeding was followed for a large uterine fibroid. In a Primary Care consultation, a globular, asymmetric abdomen was noted. A POCUS exam revealed the absence of normal structures (bowel, kidney) in the right hemiabdomen. An urgent abdominal X-ray confirmed massive displacement of bowel loops to the left. This prompted a rapid referral. A CT scan identified a giant (28x24x12 cm) fatty retroperitoneal mass. A CT-guided biopsy confirmed a benign lipomatous neoplasm, with negative MDM2 amplification ruling out liposarcoma. Staging showed no metastasis.

Originality: While giant retroperitoneal tumors are typically described in hospital settings, this case highlights the diagnostic sequence initiated in Primary Care. The use of POCUS and a plain X-ray to identify indirect signs of displacement and guide the need for advanced imaging distinguishes this pathway from standard practice.

Lessons learned and future implications: The non-visualization of normal anatomical structures on POCUS is a critical indirect sign of a space-occupying lesion, even in paucisymptomatic patients. The combination of physical exam, POCUS, and basic radiology provides key information for clinical decision-making and efficient referral.

Discussion: Increased use of POCUS in Primary Care enhances detection capability. Lipomatous masses can grow extensively before causing symptoms. Differentiation between benign and malignant lesions requires clinico-radiological and histological correlation, with MDM2 status being a key molecular determinant.

Conclusion: Giant retroperitoneal masses can be suspected from indirect findings using basic Primary Care tools. POCUS, combined with plain radiography and clinical interpretation, is decisive for early orientation and optimizing referral. This case reinforces the essential role of Primary Care in early detection and care coordination, underscoring the value of clinical ultrasound training.

(2) Royal College Of General Practitioners, Manchetser, Royaume-Uni
(3) Royal College Of General Practitioners, Wigan, Royaume-Uni

Context: Parenting is often described as the ultimate test of resilience, adaptability, and empathy. For clinicians and leaders, the unpredictability of family life mirrors the challenges of general practice and healthcare systems under pressure. Sleepless nights, competing demands, and the constant need to

improvise provide a rich metaphor for the realities of modern clinical practice and leadership. This workshop draws on lived experience to highlight how humour, reflection, and storytelling can transform personal milestones into practical leadership insights.

Objectives: • To explore parenting as a crucible for leadership development. • To foster reflection on wellbeing, psychological safety, and inclusive team culture. • To equip participants with practical strategies for flourishing in uncertain environments.

Teaching method and workshop: This workshop will use storytelling, humour, and interactive reflection to connect parenting experiences with clinical leadership. The format is designed to balance discussion, reflection, and practical application. Workshop Schedule (60 minutes)

Expected outcomes: Participants will leave with: • Practical leadership tools grounded in lived experience. • Enhanced awareness of wellbeing and team culture. • Shared strategies for resilience and adaptability in general practice.

Conclusion: By reframing the unpredictability of parenting as a source of wisdom, this workshop invites clinicians to embrace humour, vulnerability, and reflection as pathways to stronger leadership. In doing so, it embodies WONCA's themes of liberty through self-care and resilience, and fraternity through interprofessional collaboration and shared learning. Participants will leave with practical strategies that connect the personal to the professional, strengthening both individual wellbeing and collective team culture.

ID 1298- Early Lyme Disease Presenting as Atypical Erythema Migrans: The Importance of Clinical Judgement in Family Medicine

Marie-Ange MONOTE [(1)] , Frederic MILESI [(2)]

(1) Family Doctor, Privas, France
(2) Family Doctor, Dijon, France

Context: In France, about 500,000 people are affected by profound deafness. For those who cannot, or choose not to, use hearing aids, accessing primary care is often challenging due to the language barrier between French Sign Language (FSL) and spoken French. Yet, primary care should be accessible to everyone. The availability of on-site interpreters is limited, making remote video interpreting a potential alternative.

Objectives: This study set out to explore its relevance by gathering the perspectives of deaf patients and healthcare providers after using the platform.

Methods: We conducted a qualitative study based on semi-structured interviews with five deaf patients and five healthcare providers. Data were analyzed using interpretative phenomenological analysis with the software Sonal. The consultations relied on the Tadeo-Acceo platform.

Results: Both patients and providers viewed remote interpreting positively, as it facilitated clearer and more comfortable communication. While it was seen as a valuable alternative to in-person interpretation, the latter remained the preferred option. Remote interpreting was considered less essential for patients who could lip-read or speak orally.

Discussion: : This innovative and unprecedented study in Europe nevertheless has several limitations. The data are based on a small sample size, and only one video remote interpreting platform was tested. The findings are therefore not generalisable. However, several limitations to the widespread implementation of this system across the territory were identified, notably the need for a reliable internet connection and suitable audiovisual equipment, as well as its cost, which emerged as a major barrier.

Conclusion: Remote interpreting in FSL offers a promising way to improve access to primary care for deaf patients. However, its implementation requires careful consideration of funding and organizational aspects of consultations. Looking ahead, advances in artificial intelligence may provide new solutions, but at present, video interpreting

stands out as a reliable and viable option. Keywords: French Sign Language, primary care, remote interpreting, deafness, deaf patients

ID 1345- Early Recognition of Behçet's Disease Through Multisystem Assessment in Primary Care: A Case Report

Ana Maria COLLIN, Patricia Maria WIZIACK ZAGO

Faculdade São Leopoldo Mandic Araras, Araras, Brésil

Context: Prostate cancer is the most common malignant tumor among men in Brazil, excluding non-melanoma skin cancer. National estimates project 82,630 new cases annually for 2023–2025, with higher incidence in the Southeast and South regions. Early detection relies on prostate-specific antigen (PSA) testing and digital rectal examination (DRE); however, universal screening is not recommended. In Brazil, adherence to preventive measures is low and uneven, influenced by cultural resistance, limited health literacy, and insufficient professional guidance.

Objectives: To assess adherence to preventive measures for prostate cancer in Brazil, focusing on PSA testing and digital rectal examination.

Methods: A narrative literature review was conducted using PubMed, LILACS, SciELO, and the Virtual Health Library, applying MeSH/DeCS terms related to prostate cancer screening. We included Brazilian studies (2010–2025) reporting PSA and/or DRE adherence in adults.

Results: PSA adherence in Brazil ranges widely, with studies reporting 55.2% to 80.1% lifetime testing, while older adults show 75.5% prevalence. DRE adherence is consistently lower, around 61%, and a 68.3% combined PSA/DRE prevalence reflects access but not specific acceptance of DRE. Sociocultural barriers—shame, discomfort, and masculinity norms—reduce DRE uptake, whereas physician recommendation strongly supports PSA adherence and may also increase DRE acceptance. Overall, PSA adherence is moderate to high, while DRE remains moderate, and combined screening improves accuracy but faces cultural and system-level challenges.

Discussion: Preventive adherence in Brazil shows a clear contrast between PSA and DRE. PSA uptake is high (75.5% in older adults; 80.1% lifetime), while DRE remains lower (61.0%). Sociocultural barriers—shame, discomfort, and masculinity norms—strongly influence refusal. Physician guidance increases PSA testing and may improve DRE acceptance. The 68.3% combined prevalence reported by Meneghini et al. reflects screening access but a clear preference for PSA. Structural issues in the Brazilian Unified Health System, including limited specialist access and inconsistent referral pathways, also hinder adherence. Continuous education, shared decision-making, and organized care pathways are essential to improve screening outcomes.

Conclusion: PSA adherence in Brazil is moderate to high, while DRE adherence remains comparatively low. Improving screening adherence requires enhanced health education, effective communication, and strengthened care pathways within primary care.

ID 883- Early recognition of visceral leishmaniasis in a rural primary care setting

Laetitia BURET [(1)] , Isabelle HEYMANS [(1)], Helene KERSTEN [(1)], Gilles COLEMONTS [(2)]

(1) Uliege, Liege, Belgique
(2) Ssmg, Bruxelles, Belgique

Context: Complex situations are increasing in a GP Practice. But the application of clinical practice guidelines faces specific challenges in complex or multi-morbid situa-tions. In Belgium, several primary care practices experienced the Goal Oriented care to face these situations. It's about shifting form a problem-solving based practice ("What is the matter with the patient?") to an objective-oriented plan of care ("What matters to the patient?"). This approach seems to be an opportunity for the practice and the system.

Positive feedback, lessons learned, and points of attention can be shared.

Objectives: The participants will have the opportunity to discover the Goal oriented care as an approach and a methodology of work, his forces and points of attention. Place will be let to share questions and reflexion on this paradigma shift.

Teaching method and workshop: ● Teaching method 20 minutes Presentation: GOC, practice-based examples, points of attention. 20 min Work in subgroups : practice-based exercises based on cases and tools 20 min Common debate on the challenges of the approach ● Workshop schedule 3 min : w

Expected outcomes: At the end of the workshop, the participants know a bit about Goal oriented Care. Some are interested in knowing better and trying in their practice or in the professional's education.

Conclusion: Goal oriented care shows opportunities for a better alliance with the patient and his relatives, particularly in complex situations. This approach aims to give care oriented to what is important to each person in their life taking into account their resources and weaknesses.

(5) Cap Blanes, Blanes, Espagne
(6) Cap Pineda, Pineda De Mar, Espagne

Context: During 2023, the Government will promote the increase in in-person visits in primary care consultations, with the idea of recovering pre-pandemic levels.

Objectives: To analyze how the family doctor's schedule has evolved from 2017 to 2025.

Methods: A multicenter cross-sectional descriptive study with the participation of 130 family doctors from 35 primary care centers serving a population of approximately 500,000 inhabitants. Each doctor recorded the visit types of a full working day as well as the reasons for consultation in 2017, in 2019, in 2021, one week in May 2022, one week in May 2023, and one week in May 2025.

Results: 2,009 medical workdays were recorded, and 60,848 visits were analyzed. The average total visits per day between 2017 and 2025 is 30.5, with a minimum of 27.8 visits in 2019 and a maximum of 32.6 in 2025. The average number of reasons for consultation per day remained between 39.8 in 2021 and 44.8 in 2022. Face-to-face visits represented 75.23% in 2017, 67.3% in 2019, 27.78% in 2021, 47.36% in 2022, 49.3% in 2023, and 50.7% in 2025. Telephone visits accounted for 15.44% in 2017, 8.56% in 2019, 35.19% in 2021, 20.50% in 2022, and 17.3% in 2023 and 2025. Telematic visits or eConsultation practically did not exist in 2017 or 2019, appearing in 2021 representing 11.26%, 9.74% in 2022, 6.17% in 2023, and 6.68% in 2025.

Discussion: In these latest years post-pandemic we have appropriated the assistance documents of any 2017 regarding the name of visits and the reasons for consultation.

Conclusion: Despite the pandemic, the average number of visits and reasons for consultation per day has not suffered major oscillations in these 8 years of study. However, face-to-face visits suffered a drastic reduction, and it does not seem that we will recover the percentages of a decade ago. eConsultation and telephone visits have remained stable since 2023.

(2) Universitat Autònoma De Barcelona, Barcelona, Espagne
(3) Cap Canaletes, Sabadell, Espagne
(4) Cap Canet, Canet De Mar, Espagne

Context: Healthcare professions are particularly susceptible to suffering from burnout. The prevalence of this pathology is higher than in the general population. There is bibliography regarding medicine and nursing, but very little regarding the rest of the staff working in Primary Care teams.

Objectives: To determine how burnout has evolved since the pandemic across all professional groups working in primary care.

Methods: A multicenter cross-sectional descriptive study carried out at the end of the state of alarm in the months of May 2021, 2022, 2023, and 2025 using convenience sampling on a total of 1,400 workers from 30 primary care teams. Sociodemographic data were collected. We defined burnout when scores in the three subscales simultaneously exceeded the following scores: Emotional Exhaustion (EE) equal to or greater than 27 points, Depersonalization (DP) > 10 points, and Personal Accomplishment (PA) < 33 points.

Results: The response rate ranged between 33.8% in 2021 (n=406) and 20% in 2025 (n=283). Global burnout, considering all professional groups, was 25.1% in 2021, 18.1% in 2022, 11.2% in 2023, and 15.8% in 2025. By professional category, those presenting the most burnout in 2021 were the medical group, with 28.7%; in 2022, it was the administrative staff with 21.7%, who have remained the most affected group, reaching 40% in 2023 and 33% in 2025. No social worker presented severe burnout levels throughout the entire study.

Discussion: Administrative staff are the gateway to the health center. Their role is fundamental in providing care to the public. If their work is disrupted, patients may receive inadequate care.

Conclusion: In the post-pandemic era, the prevalence of global burnout in the different primary care professional groups has been reducing to a greater or lesser extent, except for administrative staff, who show exaggeratedly high values with no sign of improvement. These data compel specific corporate/governmental action directed specifically at reversing this situation.

ID 1933- ECG and "non-competitive" sport fitness: when to refer to a Sports Physician

Selima KTARI

National Institute Of Nutrition In Tunis, Tunis, Tunisie

Context: Metabolic syndrome (MetS), commonly associated with type 2 diabetes, is a major cardiovascular risk factor. However, its prevalence is increasingly recognized among patients with type 1 diabetes (T1D). The coexistence of MetS and T1D may worsen cardiovascular outcomes and complicate therapeutic management, highlighting the need for better characterization of this association.

Methods: This was a descriptive cross-sectional study including 60 patients with type 1 diabetes followed at the National Institute of Nutrition in Tunis. Metabolic syndrome was defined according to the International Diabetes Federation (IDF) criteria. Clinical, anthropometric, and biological data were collected. Associations between MetS, glycemic control, and diabetes duration were analyzed.

Originality: This study provides local data on the prevalence of metabolic syndrome in patients with type 1 diabetes, a population traditionally considered at lower

cardiometabolic risk. It highlights the emerging burden of MetS in T1D patients and emphasizes the importance of glycemic control in its occurrence.

Lessons learned and future implications: Regular screening for metabolic syndrome should be integrated into the routine follow-up of patients with type 1 diabetes, particularly in those with suboptimal glycemic control. Early lifestyle and therapeutic interventions targeting weight, blood pressure, and lipid profile may reduce cardiovascular risk. Future prospective studies with larger sample sizes are needed to better clarify causal relationships and long-term outcomes.

Discussion: The results showed a significant association between metabolic syndrome and poor glycemic control, suggesting that chronic hyperglycemia may contribute to the development of cardiometabolic abnormalities in patients with T1D. In contrast, no significant association was found between MetS and diabetes duration, indicating that factors other than disease chronicity may play a more important role. The higher prevalence observed among women is consistent with data reported in other studies and may be related to hormonal, behavioral, or lifestyle factors.

Conclusion: Metabolic syndrome is increasingly prevalent among patients with type 1 diabetes, especially in women. Poor glycemic control appears to be a key contributing factor, whereas diabetes duration does not seem to play a significant role. Strict glycemic management and comprehensive cardiometabolic monitoring are essential to improve patient outcomes.

Kaike Felix Dos REIS, Marcio Cristiano DE MELO, João Pedro Martinelli MENEZES, Maria Victória Ferreira SOUTO, Ian Rosada DE ARAÚJO

São Leopoldo Mandic, Araras, Brésil

Context: Schistosomiasis remains a severe public health issue in Brazil, reflecting an epidemiological gap sustained by social inequality. Classified as a neglected tropical disease, its persistence burdens the health system, being intrinsically linked to precarious basic sanitation and disordered urbanization.

Objectives: To analyze the spatiotemporal distribution of schistosomiasis and correlate its prevalence, morbidity, and mortality with sanitation coverage in the Brazilian macro-regions between 2013 and 2023.

Methods: An ecological time-series study was conducted in the five Brazilian macro-regions using secondary data from DATASUS/TABNET (PCE, SINAN, and SIM) for epidemiological indicators and from the Painel Saneamento Brasil for sanitation coverage. Annual rates of infection and morbidity were analyzed, and the association between schistosomiasis morbidity and lack of sewage collection was assessed using Spearman's correlation coefficient.

Results: Population proportions without adequate sewage collection exceeding 50% were associated with higher rates of infection and morbidity. The year 2013 presented the highest percentage of the population without collection (62.4%) and the highest morbidity rate (3.229). The highest positivity rate was recorded in 2014 (2.791). The Southeast region presented the highest burden of cases, followed by the Northeast region. The Spearman calculation between the morbidity rate and population without sewage access, comparing 11 temporal observations, resulted in approximately 0.909, indicating a strong positive correlation: the greater the sanitation deprivation, the higher the disease incidence.

Discussion: The results support the hypothesis that precarious sanitation conditions are key predictive factors for the persistence of schistosomiasis. The strong positive correlation observed highlights the central role of socioeconomic vulnerability in sustaining the parasite's transmission cycle. Higher morbidity and positivity rates were identified in areas with sanitation deficits, while increased notification burdens in the Southeast and Northeast regions suggest that climate,

population density, and social inequality directly influence disease distribution. The continued morbidity and mortality reflect persistent regional disparities driven by structural socioeconomic conditions over time.

Conclusion: The findings highlight sanitation deficits as a key determinant of schistosomiasis persistence in Brazil. Control strategies focused exclusively on treatment are insufficient; intersectoral public policies integrating health surveillance, primary care actions, and investments in basic sanitation are essential to reduce morbidity and mortality and address regional health inequalities.

ID 1458- Educational pathways of General Practitioners in XXX: typology, temporality and influence on medical practice

Joaquim PINTO, Rosália PÁSCOA

Usf Homem Do Leme, Uls Santo António, Porto, Portugal

Context: Statins are a cornerstone of cardiovascular disease prevention. Although generally safe, muscle-related adverse effects remain a concern, as statin-associated muscle symptoms may signal severe conditions such as immune-mediated necrotizing myopathy (IMNM). This case highlights the diagnostic challenge faced by family doctors when common symptoms mask rare but serious disease.

Methods: A 60-year-old woman with hypertension, type 2 diabetes mellitus, and long-term statin use attended a routine primary care follow-up to discuss recent blood test results. Given her very high cardiovascular risk, the consultation focused on LDL-cholesterol targets, and intensification of statin therapy was agreed. She also reported several months of fatigue and lower back pain. In the context of age and a sedentary lifestyle, these symptoms were initially attributed to degenerative musculoskeletal changes, and physical activity was encouraged with rescue analgesia prescribed. Over subsequent months, her condition deteriorated, with progressive fatigue, unintentional weight loss, and worsening generalized muscle weakness. She quickly became dependent on others for ambulation, personal hygiene, and other daily activities, prompting hospitalization. Diagnostic evaluation, including muscle biopsy, confirmed anti-HMGCR–positive immune-mediated necrotizing myopathy. Despite immunosuppressive therapy, recovery was slow and required three months of intensive physical rehabilitation to regain partial functional independence.

Originality: While IMNM is described in specialist literature, reports highlighting the primary care perspective remain scarce. This case emphasizes the family doctor's perspective, where early symptoms may be subtle and nonspecific.

Lessons learned and future implications: Persistent or progressive musculoskeletal complaints in patients receiving statins warrant periodic diagnostic reconsideration. Routine functional assessment and early measurement of muscle enzymes may facilitate earlier diagnosis and reduce preventable disability.

Discussion: Statins are widely prescribed in primary care, and musculoskeletal symptoms are common in the general population. This overlap increases the risk of misattributing early manifestations of rare statin-associated conditions such as IMNM. Continuity of care and longitudinal observation are crucial in identifying when common explanations no longer fit the evolving clinical picture.

Conclusion: IMNM is a rare but potentially severe and treatable complication of statin therapy that may initially present in primary care. Early recognition, referral, and access to rehabilitation can significantly impact outcomes, reinforcing the central role of family doctors in person-centred, safe preventive care.

(1) Collège Médecine Générale, Nancy, France

(2) Ecops Conseils, Lille, Lille, France
(3) Collège Médecine Générale, Castelnau Magnoac, France

Context: Around the world, many healthcare systems, organizations, and care teams are adapting to address current and future environmental and health challenges. This leads to recommendations for the organization and logistics of healthcare facilities, for health practionners' practices, to a positive and collective approach to health (health promotion and community health). These transformations may lead to changes in how GPs perceive their own practices. In a globalized world where the causes and consequences of modern human activities do not stop at human-made borders, sharing our perceptions, experiences, and desire for professional change toward an eco-responsible dynamic—aimed at respecting life and ensuring equity—in our practices could be a catalyst for environmental action.

Objectives: To become familiar with the main challenges and priorities for transforming our professional practices towards eco-responsible practices. To share and compare experiences across different healthcare systems and levels of structural commitment. To establish common objectives, based on field experience, for transforming practices aimed at preserving life. To envision changes in a desirable and achievable way.

Teaching method and workshop: First part 10 min :Introduction : the environmental crisis and its links to health system. Brief presentation of the different levels of health system engagement Second part 40 min: "world café" with 4 tables Table 1 : Sharing of experiences in changing p

Expected outcomes: Raising awareness of shared concerns and levers for change, stimulating creativity in support of change. Increased sense of empowerment among participants to initiate a shift in health practices that are integrated and respectful of life.

Conclusion: Sharing and reflecting collectively our practices's evolution in planetary health can be catalysts for successful transformation.

No, Madrid, Espagne

Context: Clinical case of daily practice

Methods: A 19-year-old was assessed for pain in the right inguinal region with difficulty in complete flexion of the right leg for 3 weeks of evolution without improvement with rest and analgesia. Associated loss of 20 kg of weight in recent months with night sweating and nonspecific abdominal discomfort. Analysis detects: leukocytosis 91.0000x10E3/mcl, eosinophilia 53,6 10E3/mcl. Large abdominal mass is palpable on the right flank. Abdominal CT: Large right retroperitoneal mass with pelvic extension and right inguinal region suggestive of lymphoma. Biopsy: ALK positive anaplastic large cell lymphoma. Anaplastic large cell lymphoma (ALCL) is a peripheral T-cell lymphoma that consists of characteristic large pleomorphic lymphoid cells with abundant cytoplasm and horseshoe-shaped nuclei, strongly positive CD30 immunohistochemical staining. It is notably more common in the first three decades and shows an overall male predominance. ALCL (ALK-positive) patients can present with variable symptoms. Most cases present with advanced stage (III-IV). Symptoms include peripheral or abdominal lymphadenopathy, extranodal infiltrates, bone marrow involvement, and B symptoms (such as fever and weight loss). In cases of BM infiltration, the patients can present with anemia or pancytopenia, eosinophilia, and high LDH.

Originality: The reason for consultation of a patient does not always provide guidance during an initial assessment, but the

experience of the family physician and knowing the patiente can help in diagnosis orientation.

Lessons learned and future implications: While the patients stated reason for consultation is an important starting point, it is the physicians experience and depth of knowledge about the patient that often guide the diagnostic process in primary care

Discussion: Anaplastic large cell lymphoma ia a rare, clinical and genetically heterogeneous subtype of mature T-Cell non Hodgkin lymphoma , but the incidence rate of Lymphomas among adolescents and young adults. Hodgkin lymphoma represents the most common lymphoma .

Conclusion: Lymphoma should be considered in the differential diagnosis when a young patient presents with constitutional symptoms (fever, night sweats, unintentional weight loss) and lynmphadenopathy. These B symptoms are classic for lymphoid malignances, particulary Hodgkin lymphoma and agressive non-Hodgkin lymphomas, wich are among the most common cancer in adolescents and young adults.

ID 645- Effect of semaglutide on body composition and proximal muscle strength: The STEP UP trial

Hugo RODRIGUES, Michele PEDROZO, Márcio DE MELO, Naila DE OLIVEIRA

Faculty São Leopoldo Mandic, Araras, Brésil

Context: The curricular extension was developed within the framework of the Primary Health Care - Child Health (APS V) module practices, carried out in the 2nd semester of 2025. The established themes were: belonging, bullying, cyberbullying, empathy, and non-violent communication.

Methods: Interventions took place at E.E. "Lions Clube" on Wednesdays, with 5th-semester medical students pre-planning activities aligned with the thematic axes of the Culture of Peace.

Originality: The project engaged approximately 270 students from 1st to 5th grade of Elementary School II, utilizing extra-classroom spaces to facilitate reflection, dialogue, and problematization of the addressed themes. This approach provided a unique opportunity for medical students to directly interact with the sociocultural context of schoolchildren, a key component of the School Health Program.

Lessons learned and future implications: Medical students gained valuable insights into the influence of social determinants on children's development and academic performance, reinforcing the importance of the comprehensive approach of Primary Health Care. This experience enhanced their understanding of the broader context of child health beyond clinical settings.

Discussion: The project successfully integrated medical education with the principles of the School Health Program, promoting the Culture of Peace among schoolchildren. It demonstrated the potential of curricular extension activities to enrich both medical students' learning experiences and contribute to the well-being of local communities. The use of interactive and reflective methodologies proved effective in addressing sensitive topics with young students, aligning with the goals of the School Health Program to foster healthy behaviors and a positive school environment. The direct exposure to the sociocultural context of schoolchildren allowed medical students to better comprehend the impact of social determinants on child development and academic performance, reinforcing the importance of the comprehensive approach of Primary Health Care.

Conclusion: This project bridged medical education and the School Health Program, linked to Primary Care. Engaging students in the Culture of Peace enhanced their child health understanding and positively impacted the community. The success suggests expanding similar programs with more health themes. It underscores early community engagement and interdisciplinary approaches for social and health issues within Primary Care and the School Health Program.

Stavros KORMAS [(1)], Panagiotis ANDRIOPOULOS [(2)]

(1) msc, Phd(c),general Hospital Of Kalamata, Kalamata, Grèce
(2) Assistant Professor Of Nursing, University Of The Peloponnese-Tripoli, Tripoli, Grèce

Context: The use of telemedicine and e-Health applications is increasingly relevant in healthcare, especially among nursing staff working in hospital settings.Understanding how these professionals interact with health informatics tools not only informs clinical practice but also supports the ongoing integration of digital health technologies within the National Health System.

Objectives: To explore the attitudes of nursing staff in Peloponnese hospitals towards telemedicine and health informatics applications in their workplace Methods.

Methods: A quantitative study was conducted among 305 nurses working in hospital centers across the Peloponnese region. Participants voluntarily completed a standardized and validated questionnaire distributed electronically via URL link and QR code.

Results: The sample was predominantly female (84.59%), mostly aged between 35–44 years. Over half (53.12%) showed moderate to negative awareness of telemedicine, and 68.85% reported no prior use of e-Health programs. Limited knowledge of Electronic Health Records was noted in 34.41% of respondents. Nevertheless, 69.18% believed that e-Health programs could enhance their work performance. University graduates had greater familiarity with digital health tools than those from technological institutes (59.34% vs. 31.06%). A majority (211 out of 305) expressed willingness to adopt telemedicine systems at work, although 89.5% reported lack of institutional support for professional development in e-Health.

Discussion: The findings reveal a significant gap in awareness and use of telemedicine and e-Health applications among nursing staff in Peloponnese hospitals, despite the majority recognizing their potential to improve workplace performance. This indicates a need for targeted education and institutional support to enhance digital health literacy and foster telemedicine adoption. The disparity in familiarity between university graduates and technological institute graduates suggests that educational background influences readiness to engage with health informatics. Addressing these gaps through professional development programs could accelerate the integration of telehealth services, improve patient care, and reduce healthcare costs. The current lack of institutional support highlights a critical area for policy intervention and resource allocation.

Conclusion: While past barriers to telehealth exist, hospitals have recently started adopting strategies for implementation. Telenursing programs hold promise to reduce healthcare costs and enhance service delivery. Local healthcare units increasingly utilize internal resources to develop telemedicine initiatives.

ID 2273- Effective Control of Multifactorial Cancer-Related Nausea with Ondansetron and Corticosteroids in a Palliative-Care Setting

Hugo RODRIGUES, Sofia GUTIERREZ, Márcio DE MELO, Naila DE OLIVEIRA

Faculty São Leopoldo Mandic, Araras, Brésil

Context: Child sexual violence is a serious public health issue and a violation of children's rights, with heightened vulnerability in early childhood, particularly within intrafamilial settings. Despite its protective role, sexual education faces resistance in school and family contexts, underscoring the importance of early sexual education in promoting bodily autonomy and preventing child sexual abuse.

Objectives: To develop an educational booklet on sexual education aimed at early childhood (ages 2 to 6), focusing on the prevention of child sexual abuse and violence.

Methods: This methodological study was conducted in two stages: content planning based on a literature review, and development of the educational booklet, including text, illustrations, and graphic layout, guided by pedagogical, psychological, and visual communication principles appropriate for early childhood.

Results: The educational booklet was developed using simple language, short sentences, and examples drawn from children's daily lives, combined with playful, welcoming, and visually accessible illustrations. The content addressed key topics for the prevention of child sexual abuse, such as bodily autonomy, recognition and naming of intimate body parts, differentiation between appropriate and inappropriate touch, the right to say "no," distinction between good and bad secrets, and identification of trusted adults. The material demonstrated pedagogical coherence, suitability for the cognitive and emotional development of young children, and potential to promote communication, self-esteem, and the strengthening of self-protection skills.

Discussion: The organization of the content and the selection of visual resources were aligned with theoretical frameworks of child development, particularly those proposed by Piaget, Vygotsky, and Freire, as well as scientific evidence on the prevention of child sexual violence. The playful and affirmative approach facilitates understanding of the concepts without generating fear or insecurity, while respecting fundamental ethical and psychological principles. The integration of text and images enhances information assimilation and reinforces the booklet's role as a mediator of dialogue between children and adults, strengthening the child protection network.

Conclusion: The booklet demonstrates potential as an educational and preventive tool in school, family, and community settings, contributing to children's bodily autonomy, assertive communication, and protection against sexual violence from an early age.

ID 1351- Effectiveness of the implementation of a new cardiac rehabilitation programme inlcuding primary healthcare in patients after actue coronary syndrome: a population-based analysis

Hao WU, Shugang LI

School of General Practice and Continuing Education, Beijing, Chine

Context: The co-morbidity of diabetes and hypertension is a major health threat to the elderly population, creating an urgent need for simple assessment of their shared pathophysiological mechanism—insulin resistance. The triglyceride-glucose (TyG) index serves as an effective surrogate marker, but its predictive value for co-morbidity in community-dwelling older adults requires validation with large-scale, real-world data.

Methods: This study is a cross-sectional analysis based on health examination data from 33,254 community-dwelling older adults. The TyG index was calculated and participants were grouped by tertiles. Statistical analysis was performed using SPSS 27.0. Logistic regression models were employed to assess the association between TyG index and co-morbidity risk, sequentially constructing an unadjusted model, a model adjusted for demographics (age, sex), and a fully adjusted model (further incorporating self-care ability, physical activity, smoking, and alcohol consumption) to control for confounders.

Originality: This study is the first to systematically evaluate the association between the TyG index and diabetes-hypertension co-morbidity (rather than a single disease) in a natural community-based elderly population exceeding 30,000 individuals. It also concurrently analyzed a series of TyG-derived indicators, providing more comprehensive evidence.

Lessons learned and future implications: The finding that higher exercise frequency was associated with higher co-morbidity risk suggests possible reverse causality in this cross-sectional design, highlighting the need for prospective studies to confirm causality. The results support the potential use of the TyG index as a preliminary screening tool for co-morbidity risk in primary care, which could streamline the identification of high-risk individuals.

Discussion: The analysis indicates that the TyG index is a strong independent risk factor for co-morbidity, and this association remains robust after multivariable adjustment. This reinforces the hypothesis of the central role of insulin resistance in the development of co-morbidity.

Conclusion: The TyG index is significantly associated with the risk of diabetes-hypertension co-morbidity among community-dwelling adults aged 65 and above. It represents a reliable and simple risk marker with potential public health application value.

ID 721- Effects of a green tea seed and leaf extract complex on functional dyspepsia: A randomized, double-blind, placebo-controlled trial

Boaz HASID, Yael GILLERMAN, Hanny YESHUA

Clalit Health Services, Tel Aviv, Israël

Context: Family medicine is grounded in long-term relationships, continuity of care, and a deep understanding of patients within their family and community contexts. These defining features frequently give rise to ethical dilemmas that are complex, relational, and shaped by uncertainty rather than clear-cut rules. Family doctors are required to balance competing values over time. Recognizing that many of these challenges cannot be resolved through guidelines alone, this workshop offers group-based ethical reflection as a practical and core professional developmental tool in family medicine.

Objectives: The workshop has three main objectives: 1. To strengthen participants' ability to identify and articulate ethical dilemmas arising in everyday family medicine. 2. To provide hands-on training – individually and in small groups – using real clinical cases, fostering both individual ethical reasoning and constructive feedback from peers. 3. To demonstrate how regular engagement with ethical case discussion supports professional development, resilience, and reflective practice for family doctors.

Teaching method and workshop: The workshop uses experiential and peer-based learning methods consistent with family medicine education: 1. Conceptual framing of ethical dilemmas in family medicine (10 minutes) 2. Individual engagement with a real clinical case (10 minutes)

Expected outcomes: Participants will gain a practical understanding of group-based ethical reflection as a tool for ethical competence and professional betterment in family medicine. The workshop will also serve as a refresher in applied medical ethics, emphasizing reflecti

Conclusion: The workshop conceptualizes ethical competence in family medicine as a skill that must be continuously developed through collective practice rather than a static body of knowledge. Engaging with ethical dilemmas through peer reflection supports the development of mature, reflective, and resilient family physicians, capable of navigating uncertainty while maintaining continuity, compassion, and professional integrity.

ID 2215- Effects of artistic creation involving patients and health care professionals

Emmanuel BAGOURD, Benoit CLÉMENT

University, Tours, France

Context: Climate change, resulting from greenhouse gas (GHG) emissions, is a major public health threat of the 21st century that the medical community must address. Food is a topic frequently discussed in primary care and is also a significant source of GHG emissions at the national level. Therefore, the combination of actions that are beneficial for both health and the environment has recently been conceptualized through the notion of co-benefits.

Objectives: In this context, our study aims to explore the knowledge, representations, and practices related to health- environment co-benefits of food among general practitioners in Indre-et-Loire.

Methods: A qualitative study conducted between November 2023 and October 2024 through semi-directed individual interviews with eight general practitioners in Indre-et-Loire. The analysis was conducted without data triangulation, using an approach inspired by grounded theory.

Results: The co-benefits appear to be intertwined, offering a gradual and pragmatic pathway to guide patients toward behavior changes. A primary barrier to the use of co-benefits is related to the difficulty of aligning with a patient-centered approach. Nevertheless, some doctors mention numerous clinical situations conducive to the

use of co-benefits and report various strategies aimed at adapting to patients' constraints.

Discussion: The lack of legitimacy among general practitioners emerges as the ultimate barrier to the use of co-benefits, primarily due to the political connotation of environmental issues, a lack of medical knowledge, and a feeling of isolation and helplessness. Coordination among health actors, as well as support from institutions, media, and industry, appear to be key elements in strengthening the legitimacy of general practitioners in utilizing the co-benefit approach.

Conclusion: Co-benefits appear as a concrete tool for changing the care paradigm, which general practitioners can only embrace with strong support from the entire healthcare system.

ID 110- Effects of probiotic Bacillus coagulans MTCC 5856 on symptoms and fecal microbiome in adults with functional constipation: a randomized double-blinded, placebo-controlled trial

Lamara MANUKYAN

Armenian Association Of Internal Medecine, Yerevan, Arménie

Context: Geriatrics

Objectives: WHO defines intrinsic capacity (IC) as the combination of the individual's physical and mental, including psychological, capacities; and functional ability (FA) as the combination and interaction of IC with the environment a person inhabits. The basis of healthy aging is the maintenance of intrinsic capacity and functional ability throughout the life cycle.

Methods: Consulting and screening testing of intrinsic (cognitive and physical) capacity using the WHO Integrated Care for Older People (ICOPE) screening tool was conducted 120 elderly residents aged 65 and older in 5 outpatient clinics in Yerevan, of which 55% were aged 65-74, 31.6% were aged 75-84, and 13.4% were aged 85 and older.

Results: As a result of screening, cardiovascular diseases prevail (ischemic heart disease, arterial hypertension 2-3 stages, chronic heart failure 2-3 functional class) - 87%. In second place is chronic ischemia of the brain - 67%. Metabolic disorders (metabolic syndrome, dyslipidemia) - 45%, type 2 diabetes - 20%; osteoarthritis - 35%; anemia (iron and B-12 deficiency) - 22%; hypothyroidism and hiperthyroidism - 22%; mioma, prostate adenoma and other tumor diseases - 18%; gastroduodenal, intestinal ulcer - 10%. Geriatric syndromes (GS) are: memory loss and cognitive impairment - 80%, senile dementia - 73%, senile frailty - 70%, urinary incontinence - 68%, sarcopenia - 64%, age-related constipation - 60%, pain syndrome - 55%, loss of mobility - 50%, problems with chewing food - 47%, unintentional weight loss - 42%, voice changes- 28%.

Discussion: Geriatric syndromes associated with chronic noncommunicable diseases (CND) worsen their course and lead to adverse outcomes. Higher education has 30%, 20% of whom has preserved memory, and 10% has partial loss of short-term memory. 21% workers have relatively preserved cognitive health. The frequency and severity of geriatric syndromes in single elderly people is 2-3 times more common than in adults living families.

Conclusion: Prevention, early diagnosis and treatment of geriatric syndromes improve the prognosis, quality of life and prolong life expectancy of elderly people. Changing the environment, preventing social loneliness and combating ageism will lead to increase adherence to treatment of CND and correction of GS, improved social integration and maintenance of active, healthy and dignified longevity.

(1) Chi-Mei Medical Center, Tainan, Taïwan
(2) National Kaohsiung Normal University, Kaohsiung, Taïwan

Context: Healthcare workers are vulnerable to sleep disturbances due to shift work, circadian disruption, and high occupational stress. Poor sleep quality negatively impacts alertness, mental well-being, and patient safety. Non-pharmacological sleep interventions suitable for irregular schedules remain limited. Brain Dynamic Audio Stimulation has emerged as a potential auditory method for promoting neural relaxation and improving sleep, but evidence in frontline healthcare personnel is limited.

Objectives: To evaluate the effectiveness of Brain Dynamic Audio Stimulation in reducing insomnia severity among healthcare professionals experiencing subjective sleep disturbances.

Methods: This prospective single-group pretest–posttest study recruited 15 healthcare workers aged 20–65 years with at least one month of subjective sleep disturbance. Exclusion criteria included use of sedative or psychiatric medication, diagnosed sleep disorders, epilepsy, major psychiatric or neurological illness, significant hearing impairment, or pregnancy/breastfeeding. Participants completed a standardized Brain Dynamic Audio Stimulation protocol, which consisted of a 30-minute session delivered through headphones each night before bedtime for two consecutive weeks. Insomnia severity was assessed using the Insomnia Severity Index (ISI) before and after the intervention. Pre–post differences were analyzed using paired-samples t-tests with effect size estimation.

Results: Fifteen participants (14 females, 1 male; mean age 40.8 years) were enrolled. All participants completed the intervention. Mean ISI scores decreased from 10.0 (SD=5.55) to 4.27 (SD=2.69), representing a mean reduction of 5.73 points ($t=5.08$, $p<0.001$) and a large effect size (Cohen's $d=1.31$). Those with higher baseline insomnia severity demonstrated the largest improvements.

Discussion: This pilot study offers preliminary evidence that Brain Dynamic Audio Stimulation may be associated with reductions in insomnia severity among healthcare workers. Its brief, structured format appears compatible with shift-based routines. Nonetheless, findings should be interpreted cautiously given the small sample and single-group design. Larger controlled studies are needed to further assess effectiveness and generalizability.

Conclusion: Brain Dynamic Audio Stimulation may serve as a feasible non-pharmacological approach to support sleep health among healthcare personnel in high-stress clinical settings.

Context: Mindfulness is used for therapeutic purposes through MBSR programs. They might be quite difficult to organize. An alternative has emerged: the practice of mindfulness through digital media.

Objectives: The main objective of this study is describing and analyzing the motivations and expectations of general medicine patients, using any application enabling the practice of mindfulness via audio, podcast and/or video.

Methods: This qualitative study is inspired by the grounded theory method. 14 interviews were conducted in 2025, in person, by phone or videoconference. This study followed the COREQ grid criteria.

Results: This study identified various motivations to start mindfulness practice through digital tools such as an outside opinion, media, psychological or somatic diseases. Learning this practice follows a

complex cycle. There are expectations about these digital tools, concerning personalization and practicality. By exercising, patients relieve their symptoms on their own and manage their daily emotions more easily. The most convinced ones will seek to share this practice with others.

Discussion: The role of general practitioners could be to guide patients in their use, prioritizing free and accessible tools. Eventually, the development of mental health apps supported by the national health insurance could be a reliable alternative.

Conclusion: In conclusion, these digital mindfulness tools are already used by patients for self-medication purposes.

ID 990- Elevation of Liver Enzymes in a Patient with Obesity and Dyslipidemia on Statin Therapy: Importance of the Differential Diagnosis Between PBC and Drug-Induced HepatitisJHJ

Kaike Felix Dos REIS, Marcio Cristiano DE MELO

São Leopoldo Mandic Araras, Araras, Brésil

Context: LGBTQIAPN+ people in Brazil experience persistent structural vulnerabilities shaped by discrimination, stigma, and gaps in health-system responsiveness. These factors contribute to inequities in access, continuity of care, and protection from violence within the Unified Health System (SUS). Despite regulatory advances, national surveillance systems still present limited and fragmented indicators on gender and sexual minorities, restricting the ability of primary care teams to recognize patterns of vulnerability and plan inclusive actions.

Objectives: To analyze demographic, social, health-related, and human rights indicators of LGBTQIAPN+ populations in Brazil using national datasets, identifying spatial patterns that may inform primary care strategies.

Methods: A descriptive quantitative study was conducted using secondary, anonymized, publicly accessible data from the National Ombudsman for Human Rights (Disque 100) and the Brazilian Institute of Geography and Statistics (IBGE), including the 2022 Census and the National Health Survey. Analyses examined temporal trends, spatial distribution of reports, and demographic and social profiles of affected groups. Indicators included notifications of rights violations, characteristics of victims and suspects, sociodemographic patterns, and health-service utilization. Because all datasets are public, ethics approval was not required under Brazilian Resolution 510/2016.

Results: Across datasets, LGBTQIAPN+ individuals—particularly transgender people, gay men, lesbians, and bisexuals—accounted for thousands of reported violence cases despite demographic minority status. In 2024, 122 murders of trans people were recorded, mainly involving travestis and trans women. Reports frequently listed LGBTQIAPN+ individuals as both victims and suspects. Health indicators showed low reporting and limited follow-up within SUS. Hospitalizations for gender-affirming procedures increased, and marriage data concentrated among younger adults.

Discussion: The findings reveal persistent structural inequality affecting LGBTQIAPN+ populations in Brazil, marked by high violence, weak health-system responses, and insufficient surveillance. Underreporting reflects stigma, limited professional training, and lack of standardized indicators on sexual orientation and gender identity. These gaps hinder care and demand targeted interventions in the SUS.

Conclusion: The study increases visibility of LGBTQIAPN+ health needs and reveals surveillance gaps that hinder equitable, person-centered primary care. Results stress the need for data collection, monitoring of violence, and inclusive care pathways for gender-affirming care, mental health, and violence prevention. Training and policies are key to reducing inequalities in SUS.

ID 1431- Embedding CAREMELO-Driven Digital Engagement to Transform Long-Term Condition Management and Reduce Rural Health Inequalities in Primary Care Across England

Karen GULLY

Strategic Programme For Primary Care In Wales, Cardiff, Royaume-Uni

Context: Wales is a small country with a strong political focus on social justice. The national strategy promotes service integration and community-focussed care but there has been limited progress. Costs are rising and there is a reliance on a medical model that increases dependence on services.

Methods: A community orientated model defines 60 local areas for the development of primary and community care services. Local clinical leadership and community engagement has delivered a variety of local solutions (expanding the roles of primary care nurses, community pharmacists, physiotherapists, mental health teams and allied health professionals). Fraternity is a key enabler - bringing professionals together to share experience and develop common goals. The national policy places a high value on equality, but the system is slow to change. GPs have a growing desire for 'liberty' - to allow more rapid local problem solving and decision making.

Originality: The Wellbeing off Future Generates Act requires public bodies in Wales to improve social, economic, environmental and cultural wellbeing but also to think long-term, ensuring that future generations benefit from actions taken now. This requires cultural change, prioritising informed choice and measuring value for the individual

Lessons learned and future implications: Large healthcare organisations tend to centralise decision making, to gain a sense of 'control', particularly when there are workload and financial pressures. We are working to increase confidence in a more localised approach, negotiating the freedom for primary care teams to fully utilise their unique expertise.

Discussion: A Primary Care Model for Wales has demonstrated the potential of local partnerships, to achieve greater equity and deliver a sustainable approach. With small local budgets teams can explore new approaches that are specifically tailored to their context; however, the full potential of this approach will not be achieved without greater freedom to act locally

Conclusion: Primary care clinicians in Wales have structures that support fraternity, providing time and resources to develop solutions to improve equity. However, without more freedom to act they will be unable to deliver the ambition of our national commitment to future generations.

ID 394- Embodied Patient-perspective simulations in nursing education: an exploratory qualitative study

Katie BROWN

University Of Glasgow, Glasgow, Royaume-Uni

Context: Climate change and environmental degradation pose escalating threats to global health, making sustainability a critical component of medical education. The XXX require new doctors to understand the health-related effects of climate change and promote sustainable healthcare practices. Despite this mandate, many medical educators lack the confidence and knowledge to teach sustainability effectively. Embedding sustainability in the curriculum is essential to prepare future doctors for complex health challenges and to meet the XXX commitment to achieving net-zero carbon emissions.

Methods: This research explored medical educators' knowledge and attitudes toward sustainable healthcare and developed a faculty development programme to support curriculum integration. The programme aimed to equip educators with the knowledge, skills, and values needed to confidently teach sustainability concepts. It incorporated interactive workshops, case-based discussions, and resource toolkits tailored to enhance confidence in integrating sustainability into clinical teaching. Key areas included understanding sustainable healthcare systems, mapping patient journeys through a sustainability lens, and fostering problem-solving skills for complex health challenges. Evaluation was conducted through participant feedback and thematic analysis of responses.

Originality: While sustainability education is increasingly recognized as essential, most initiatives focus on student learning rather than faculty development. This programme is innovative in addressing the educator knowledge and confidence gap as a prerequisite for successful curriculum integration. Literature review revealed limited evidence on similar faculty-focused interventions, highlighting the novelty of this approach.

Lessons learned and future implications: Evaluation demonstrated significant improvements in educators' understanding of sustainable healthcare principles and their confidence in teaching sustainability. Participants valued practical applications such as healthcare systems and patient journey case studies, and interdisciplinary collaboration enriched perspectives on sustainable healthcare delivery.

Discussion: Future work should focus on scaling faculty development initiatives, fostering resource-sharing across institutions, and embedding sustainability as a cross-cutting theme within spiral curricula.

Conclusion: Faculty development is essential for embedding sustainable healthcare education within medical curricula, aligning with XXX guidance and XXX sustainability goals. Empowering educators with knowledge and practical tools enhances the relevance of sustainability teaching and prepares future doctors to become adaptive, environmentally conscious leaders in healthcare.

Context: Falls and functional decline are major health concerns in the elderly population, leading to significant morbidity. Vitamin D deficiency is highly prevalent in this group. However, its direct correlation with balance disorders, muscle strength, and fall risk in primary care settings remains a subject of ongoing clinical debate.

Objectives: To evaluate the relationship between serum Vitamin D levels, balance alterations, functional capacity, and the incidence of falls in community-dwelling people over 65 years of age.

Methods: A descriptive, observational study was conducted with participants aged >65 recruited from five primary care centers. We collected sociodemographic, clinical, and functional data. Key assessments included balance tests (unipodal test, posturography), the Short Physical Performance Battery (SPPB), and muscle strength measurements. Serum 25-hydroxyvitamin D levels were analyzed, considering levels ≥20 ng/ml as adequate. A prospective follow-up of falls was performed over a 12-month period to record new events. Statistical analysis included descriptive and comparative methods using the Chi-square test (RStudio 4.3.0).

Results: A total of 922 individuals participated. 60% presented adequate Vitamin D levels, 32% had inadequate levels, and 8% showed deficiency. Statistically significant associations were observed between Vitamin D levels and sex ($p = 0.0047$), performance in the unipodal test ($p = 0.0181$), and habitual physical activity ($p < 0.0001$). However, no significant associations were found with posturography ($p = 0.265$), SPPB score ($p = 0.350$), extensor strength ($p = 0.167$), previous history of falls ($p = 0.477$), or new falls recorded during the 12-month follow-up ($p = 0.110$).

Discussion: Adequate Vitamin D levels correlate significantly with better performance in the unipodal balance test and higher physical activity, suggesting a potential role in preserving specific motor functions. However, contrary to some expectations, Vitamin D levels alone were not predictive of falls or other functional test outcomes in this specific cohort.

Conclusion: While Vitamin D is associated with specific motor function indicators like the unipodal test, it does not appear to directly influence fall risk in this population. These findings highlight the multifactorial complexity of fall prevention and suggest Vitamin D assessment should be part of a broader functional evaluation.

ID 1286- Empathy in Primary Care: Insights from an Experiential Disability Simulation

Samsida Mama-O ABATON

San Lazaro Hospital, Manila City, Philippines

Context: The advent of antiretroviral therapy (ART) has significantly enhanced the prognosis of individuals living with HIV (PLHIV), mitigating morbidity and mortality as well as improving life expectancy.

Objectives: This study aims to assess the impact of ART initiation on the health-related quality of life (HRQoL) of PLHIV attending a national tertiary infectious disease hospital, using a validated multidimensional assessment tool.

Methods: Prospective cohort study among newly diagnosed HIV-positive adults enrolled in San Lazaro Hospital. Participants completed the WHOQOL-HIV BREF questionnaire and evaluates six domains. Data were analyzed using descriptive statistics to summarize socio-

demographic and clinical characteristics and HRQoL scores.

Results: The study enrolled 68 participants, primarily young adults aged 19-29 years (52.9%), male (95.6%), single (98.5%), and employed (60.3%). Most (83.8%) had baseline CD4 counts <200 cells/mm³, indicating advanced immunocompromise. Baseline HRQoL scores showed moderate quality of life, with the highest scores in the level of independence (mean 3.29, SD 0.505) and environment domains (mean 3.28, SD 0.387). The lowest scores were recorded in the social relationships domain (mean 2.77, SD 0.608), suggesting issues with interpersonal support and social integration.

Discussion: The baseline findings show that most participants were young, male, single, and employed, reflecting the typical demographic pattern seen in Philippine HIV cases. Despite being economically active, many were already in a state of advanced immunosuppression at diagnosis. High independence scores indicate that they can still perform daily activities, likely due to their young age and active employment status. The environment domain also scored well, influenced by the study setting in a national tertiary hospital where healthcare access, information, and support services were readily available. Moderate physical and psychological scores suggest common pre-treatment symptoms such as fatigue, anxiety, and emotional distress, emphasizing the need for early medical and mental health interventions. The lowest social relationships score highlights persistent stigma, fear of disclosure, and social isolation experienced by PLHIV in the Philippines.

Conclusion: Baseline findings revealed moderate HRQoL across all domains, highlighting significant social relationship challenges. This underscores the importance of integrating psychosocial and environmental interventions with clinical care during ART initiation. Further assessments at three-month follow-up will evaluate changes and predictors of HRQoL improvements.

(1) Usp, Americana, Brésil
(2) University of São Paulo, Americana, Brésil

Context: Drug addiction and helplessness are strongly linked concepts shaping chemical dependence. Family medicine is crucial for understanding the determinants of mental suffering in psychosocial care and inpatient services, coordinating care through teaching and clinical actions.

Methods: This report presents a study of three cases using the INTERMED tool to assess the impact of social determinants of health on the suffering and quality of life of patients with mental disorders in a Psychosocial Care Center. We also examined perceptions of social stigma regarding psychoactive substance use, mental health treatment, previous hospitalizations, and the influence of family and societal prejudice on patient engagement, treatment adherence, and changes in life perspective. All patients had physical, mental, and social multimorbidity and documented problems related to substance misuse. INTERMED was applied at the first consultation, and patients were evaluated three times during their stay in the mental health service. They were interviewed about the role of stigma in their lives, and all reported that societal prejudice created barriers to attempts at behavioral change, such as returning to work or school, improving lifestyle, and reducing chemical dependence. The study was approved by the Research Ethics Committee.

Originality: This is a pioneering use of the INTERMED instrument to visualize the impact of social vulnerabilities and health-related stigma on the functioning of patients with severe mental disorders and substance use in the context of family medicine in Brazil.

Lessons learned and future implications: Mental suffering emerges from life histories marked by social and personal disruptions. The abusive use of drugs is linked to external stressors and the individual's capacity to manage stress and adopt behavioral changes that support quality of life and well-being.

Discussion: The INTERMED score above 20 indicated complexity due to interacting factors like chronic diseases, polypharmacy, and fragmented care. Stigma made patients feel devalued, leading to poor psychopharmacology adherence due to fear of dependence. They noted medication alone would not improve function. Fragile family structures, limited social support, poverty, housing issues, and difficulty accessing primary care contributed to disorganized care.

Conclusion: Integrating mental health services into family medicine training and practice is highly relevant for strengthening health care through a biopsychosocial perspective.

Corresponding author: Emilly Barboza Rasmussen, emillyrasmussen@usp.br

ID 1590- Empowering Educators for Global Health: Embedding Sustainability in Medical Education

Boumaza ABD-ELATIF, Rachel COLLIGNON PORTES, Julien LE BRETON

Uvsq, Montigny-Le-Bretonneux, France

Context: Chronic pain is a major public health problem, affecting 20% of the French population. The General Practitioner (GP) is the linchpin of its management, but numerous studies suggest that this management is a source of difficulty and frustration for practitioners. A better understanding of these challenges is essential to improve training and the organization of primary care.

Objectives: The main objective of this study was to determine the difficulties encountered by general practitioners in the management of chronic pain. Secondary objectives were to analyze their practices and their emotional experience when facing these complex situations.

Methods: This was a qualitative, exploratory, and multicentric study, conducted with certified and established general practitioners. The data collection method relied on semi-structured Peer Groups (GDP), allowing for a free and in-depth discussion of real clinical cases. The data were analyzed using an inductive thematic approach, with triangulation of analyses by the three authors to ensure the reliability of the results.

Results: The analysis identified and structured the difficulties into three main categories: 1.Patient-related difficulties: Complicated psychosocial context, subjectivity of pain, medical nomadism, unrealistic expectations. 2.Physician-related difficulties: Lack of initial and continuing training, feeling of powerlessness, fear of iatrogenesis. 3.Health system-related difficulties: Insufficient consultation time, difficulty accessing specialized structures (SDC), and lack of interprofessional coordination. The study also highlighted a strong emotional impact on GPs, notably a feeling of loneliness, powerlessness, and discouragement when facing these chronic situations.

Discussion: The results confirm and enrich the existing literature by proposing a clear categorization of the barriers to optimal management. They underline the necessity of a global and multidisciplinary approach, and highlight the urgent need for support and training for GPs. The main difficulty lies in managing the psychosocial context, uncertainty, and chronicity, which requires an adaptation of practices and a recognition of the complexity of the task.

Conclusion: The management of chronic pain in general practice is a major challenge, a source of difficulty for practitioners. The results of this study call for concrete actions on training, the organization of primary care, and support for general practitioners, in order to guarantee a better quality of life for chronic pain patients.

ID 673- Empowering Family Doctors in COPD Care. Hands-on learning in treatment guidelines, inhaler technique, and patient motivation

Jelizaveta KALEDINA

Doctor, Tallinn, Estonie

Context: Managing a CaReMeLO patient in primary care can be very challenging. Understanding that obesity is a life-changing chronic condition and not just a simple cosmetic issue is essential. It is a condition that needs to be taken seriously by the patient, their family, and the doctor, and treated correctly and in a timely manner. Furthermore, a CaReMeLO patient usually requires special care and support. Type II diabetes, chronic heart failure, CKD, and other conditions may affect a CaReMeLO patient's physical and mental health, potentially leading to severe social isolation. The problem may, in turn, worsen, placing a greater burden on the patient's relatives and the healthcare system.

Objectives: For a family physician, striking a balance between the disease and respecting the patient as an individual can be challenging, especially in a context where stigmatisation is no longer tolerated. In my workshop, I would like to discuss with the group how we can encourage both the patient and their family to remain active and sustainable in this journey, while enhancing the family physician's role in managing complex medical cases.

Teaching method and workshop: 45-Minute Workshop for 30 Participants The participants will be divided into 3 groups of 10. 1. Each group will present the needs and perspectives of different stakeholders: the patient, their family, the family physician, as each role plays a significant

Expected outcomes: Improved understanding of each group, their needs, and potential barriers, leading to better communication and support.

Conclusion: Enhancing the role of family physicians in managing CaReMeLO patients and in connecting the patient with their family.

(2) Medical Centre For Occupational Health Rijeka, Family Medicine Office, Rijeka, Croatie
(3) University Of Rijeka, Faculty Of Medicine, Rijeka, Croatie

Context: Lower urinary tract symptoms (LUTS) are common among adults and can impair physical, psychological, and social functioning. Despite this, the biopsychosocial aspects of LUTS—especially the role of symptom awareness—remain insufficiently explored. Understanding how symptom perception affects well-being is important for improving care in primary healthcare.

Objectives: The primary objective was to determine whether awareness of LUTS symptoms is associated with poorer psychosocial outcomes and reduced quality of life. Additional objectives were to examine associations between LUTS type and general or social anxiety; assess whether younger adults experience greater social isolation than older adults; and evaluate whether perceived environmental support influences the subjective severity ("bothersome") of LUTS.

Methods: A cross-sectional study was conducted among 191 adults aged 18–90 years in Primorje-Gorski Kotar County, Croatia. LUTS presence and type were assessed using a validated educational screening questionnaire. Participants were categorized into three awareness groups: no LUTS, unaware LUTS, and aware LUTS. General anxiety was measured using GAD-7, social anxiety using the Liebowitz Social Anxiety Scale, and quality of life using WHOQOL-BREF. Statistical analyses included chi-square, Mann–Whitney U, Kruskal–Wallis tests, and Spearman correlations ($p < 0.05$).

Results: LUTS were identified in 93.7% of participants, most commonly storage symptoms. No significant associations were found between LUTS type and general or social anxiety, and social quality-of-life scores did not differ across age groups ($p > 0.05$). The key finding was that participants aware of having LUTS showed significantly poorer physical quality of life compared with those without LUTS and those unaware of their symptoms ($p = 0.003$). Perceived environmental support did not influence symptom severity.

Discussion: These findings suggest that symptom awareness exerts a stronger influence on patient experience than symptom type or demographic factors. Heightened bodily focus and altered perception of discomfort may contribute to reduced physical well-being, independent of anxiety or social functioning.

Conclusion: Symptom awareness emerged as the strongest predictor of reduced physical quality of life. Integrating patient education, supportive communication, and a biopsychosocial approach into routine LUTS management may help mitigate the negative effects of symptom perception on overall well-being.

ID 847- Empowering Family Physicians: Practical Approaches to Prescribing Physical Activity in Disadvantaged Groups

Anna DI GIUSEPPE, Vanessa PALMA, Elodie ROQUETTE

Université De La Réunion, Saint Pierre, France

Context: Over the past five years, a mandatory uniprofessional Therapeutic Patient Education (TPE) training programme has been implemented for general practice trainees. From 2025 onward, this programme has evolved into an interprofessional training model, bringing together general practice trainees and advanced practice nurses, with planned future inclusion of additional health professions. The 42-hour programme is delivered by an interprofessional teaching team including physicians, nurses and a trained patient-partner, leading to a formal certification.

Objectives: The objectives are to: Compare how TPE training is currently implemented across universities and primary care departments in different countries; Identify barriers and facilitators to the development of interprofessional TPE programmes; Mobilise collective intelligence to co-construct realistic and transferable strategies to overcome these barriers in primary care settings and during residency training

Teaching method and workshop: The workshop will begin with a brief presentation of the current interprofessional TPE training model and key lessons learned from its implementation. Participants will then work in mixed professional groups to map their own local TPE training models (if

Expected outcomes: Participants will: Discover a wide diversity of TPE training models in Europe; Identify priority action for developing or strengthening interprofessional TPE programmes; Leave with a shared implemented support document to facilitate dialogue with academic

Conclusion: This workshop aims to know and optimise TPE teaching practices in primary care and to support the emergence of more structured interprofessional educational pathways across Europe.

ID 404- Empowering Municipal Health: The Role of Family Doctors in Leading Local Health Departments

Jane PUNGUIL

Mayaguez Medical Center, Mayaguez, Porto rico

Context: This case highlights a rare instance of Mycoplasma pneumoniae–associated myocarditis and cardiomyopathy leading to a cardioembolic stroke in a young adult, emphasizing the need to consider extrapulmonary infection effects and underlying heart disease when evaluating stroke in young patients.

Methods: A retrospective descriptive review of electronic medical records was performed, extracting clinical, diagnostic data and available media. Documenting al in a standardized case report format.

Originality: This case is original because it presents a rare combination of Mycoplasma pneumoniae–associated myocarditis, newly diagnosed LV non-compaction, and cardioembolic stroke in a young adult—an uncommon intersection that highlights a unique diagnostic challenge and offers important insights for evaluating stroke in young patients.

Lessons learned and future implications: This case emphasizes the importance of broad cardiac evaluation in young stroke patients, as infections like Mycoplasma pneumoniae can trigger severe myocarditis and reveal underlying LV non-compaction. Early cardiac imaging, awareness of infection-related cardiac injury, and coordinated multidisciplinary care are key to preventing recurrent embolic events and sudden cardiac death.

Discussion: This case illustrates a rare presentation of cardioembolic stroke in a young adult caused by severe non-ischemic cardiomyopathy due to left ventricular non-compaction (LVNC), likely unmasked or exacerbated by Mycoplasma pneumoniae and concurrent viral infections. While M. pneumoniae typically causes mild respiratory illness, it can lead to myocarditis and significant cardiac dysfunction. The patient's severely reduced ejection fraction predisposed him to thromboembolism, resulting in stroke. This case highlights the importance of early cardiac evaluation in young stroke patients, considering both structural heart disease and infection-related cardiac injury, and underscores the need for multidisciplinary management, including anticoagulation, heart failure therapy, and arrhythmia prevention, to reduce the risk of recurrent embolic events and sudden cardiac death.

Conclusion: This case illustrates a rare but critical cause of stroke in young adults, left ventricular non-compaction, potentially triggered or unmasked by M. pneumoniae-associated myocarditis. The combination of neurological symptoms, respiratory illness, and cardiac dysfunction underscores the need for early cardiac imaging and infectious workup in young stroke patients. Prompt recognition and multidisciplinary management are key to optimizing outcomes.

ID 760- Enhancing equity through patient and public involvement in cardiovascular prevention in primary care

Marijana TOMIC SMILJANIC, Branka SOSIC

Specialist In General Medicine, Belgrade, Serbie

Context: Rheumatoid arthritis (RA) is characterized by chronic inflammation, joint destruction and an increased risk for cardiovascular morbidity. Dietary intakes of omega-3 and omega-6 polyunsaturated fatty acids affects inflammation and cardiovascular risk.

Objectives: To assess the influence of omega 3 and omega 6 fatty acids in patients with rheumatoid arthritis through inflammatory parameters and through oxidative stress.

Methods: 60 patients with RA is divided into the first group (20 patients), to which 5 of gel capsules Omega 3 for 3 months, the second group (20 patients) who have taken after 3 of gel capsules Omega 3 and two gel capsules oil evening primrose oil for 3 months, and the third, control group (20 patients) who were taking no supplements. Analysis of biochemical parameters of endothelial function and parameters associated with acute and chronic effects of oxidative stress: (O2·-, H2O2,NO·, TBARS, SOD, CAT, GSH) was performed in the Laboratory of Cardiovascular Physiology at the Faculty of Medicine in Kragujevac. Measurements were performed on the AnalyticJenaSpecordS 600 spectrophotometer.

Results: Prooxidant and antioxidant actions are parameters in the groups of patients with RA who received supplementation with omega-3 and omega-6 fatty acids showed a decrease in oxidative stress and the increase in activity of

the antioxidant protection system. Supplementation of omega 3 and omega 6 fatty acids in patients with RA affects the reduction in disease activity.

Discussion: .In subjects suffered from rheumatoid arthritis who took concentrated fish oil supplements with omega-3 fatty acids as a dietary supplement, there was an increase in the level of antioxidant protection parameters and a decrease in the level of prooxidants, which was confirmed by group analysis.

Conclusion: It has been observed that in some people the clinical effect is absent. Genetic variations affect the way the body responds to certain nutrients and food components, and materials that can break down and properly utilized. That's why some individuals have it and some don't, which is the subject of further research into genetic variants in the genes that encode enzymes for the metabolism of omega 3 and omega 6 fatty acids.

ID 945- Enhancing Insulin Injection Timing and Glycemic Outcomes Using a Connected Insulin Cap: A Multicenter Primary Care–Endocrinology Collaboration Study

Assumpta FERRER, Olin BAZURCO, Agustina LUJAN, Chirag NANDWANI, Sayra ALMONTE, Ariadna RODRIGUEZ, Jorge DIAZ

Cap El Pla . Ics, Sant Feliu De Llobregat, Espagne

Context: Inferior vena cava (IVC) ultrasonography is an increasingly valuable tool for managing patients with chronic heart failure (HF), yet its use in primary care settings is not well described.

Objectives: This study aims to evaluate the prevalence of ultrasound-assessed congestion in HF outpatients seen in primary care.

Methods: A cross-sectional observational study was conducted involving all patients diagnosed with HF in five consultation units at our primary care center in Sant Feliu de Llobregat, a city within the province of Barcelona, who agreed to participate, and they could travel to the centre. A total of 120 patients over 18 years of age were contacted. Collected data comprised sociodemographic factors and cardiovascular clinical characteristics. Ultrasound congestive HF was defined as an IVC diameter ≥21 mm or an inspiratory collapse <50%. Clinical congestion HF was considered present if two or more relevant symptoms worsened (dyspnea, edema, weight gain, jugular vein distention). The IVC ultrasonography was performed by doctors from the center trained in 3 sessions of 2 hours each. A descriptive analysis was performed.

Results: Finally 77 participants were included and 43 excluded due to multimorbidy or mobility problems. Were female 47(61.0%), with a mean age of 80 years. Fifty one (66.2%) patients had more than two cardiovascular comorbidities, 52(67.5%) had HFpEF, and 21(27.2%) had HFrEF, and 53 (68.8%) had polypharmacy (>5 medications). Ultrasound evidence of congestion was found in 17 participants (22.1%), whereas clinical congestion was identified in only 6 (7.8%).

Discussion: Ultrasound-detected congestion appeared more frequently than clinical congestion during HF follow-up visits in primary care. In older populations, where clinical assessment is often challenging, ultrasonography could have a prominent role easy to perform for evaluating congestion status.

Conclusion: The prevalence of ultrasound-assessed congestion in outpatients seen with HF treated in primary care is high. IVC ultrasonography could be a valuable tool for the follow-up of patients with HF, allowing for early identification of patients at high risk of deterioration. These findings highlight the need for further research.

ID 249- Enhancing Occupational Safety in Medication Preparation: A Randomized Controlled Trial of an Innovative Ampoule-Opening Device

Munazza ASAD, Unab KHAN

Aga Khan University Hospital, Karachi, Pakistan

Context: Precision Public Health (PPH) is reshaping global healthcare by using data to deliver targeted, timely, and population-specific interventions. Since Family physicians serve as the first point of contact for most health concerns; the integration of PPH into primary care is both essential and underdeveloped. Family Medicine is uniquely positioned to operationalize precision strategies, translating population data into individualized care, strengthening prevention, and improving community outcomes. Despite the availability of public health data, primary care teams often lack structured methods to apply it in real practice. This workshop, "Family Medicine in Precision Public Health: Building the Foundation of Better Care," addresses this gap by offering a practical, case-based approach. Participants will learn how family physicians can use local data to design targeted interventions, improve continuity of care, and enhance population health.

Objectives: Understand PPH in family medicine. Recognize the physician's role in data-driven care. Plan targeted prevention and management strategies. Enhance teamwork and community partnerships for better outcomes.

Teaching method and workshop: This workshop uses a blended, interactive format combining (2- hour): Brief concept introduction to establish key principles of Precision Public Health and its link to Family Medicine. Case-based small-group discussions. Collaborative problem-solving wher

Expected outcomes: Participants will: Understand the synergy between family medicine & precision public health. Recognize how data-driven, tailored approaches can be implemented in primary care. Develop action points to integrate precision public health in their own context

Conclusion: This workshop highlights how Family Medicine is central to translating Precision Public Health into meaningful, patient-level impact. By grounding public health data in everyday clinical practice, family physicians can identify high-risk groups, implement targeted interventions, and strengthen continuity of care. Through case discussions, participants reinforced that precision approaches are most effective when operationalized at the primary care level. As health systems evolve, integrating PPH into Family Medicine offers a powerful pathway to more responsive, equitable, and outcomes-driven care.

(1) Hospital Sahloul, Sousse-Tunisie, Tunisie
(2) Hospital Sahloul, Sousse-Tunisie, France

Context: Les masses surrénaliennes, souvent découvertes fortuitement, peuvent être bénignes ou malignes et sécrétantes ou non ; leur évaluation clinique, hormonale et radiologique est essentielle pour guider la prise en charge, notamment l'indication chirurgicale.

Objectives: Décrire le profil clinique, paraclinique, étiologique, thérapeutique et évolutif des masses surrénaliennes (MS).

Methods: Etude rétrospective, menée sur 101 patients hospitalisés au service de médecine interne du CHU Sahloul, Sousse et qui présentent une masse surrénalienne durant la période entre 2002 et 2025

Results: IL s'agissait de 101 patients, l'âge moyen était de 59,8 ans avec une prédominance féminine. Les circonstances de découverte de la masse surrénalienne étaient : une hypertension artérielle (42,57 %), une altération de l'état général (33,66 %), une douleur abdominale (26,73 %) et une triade de Ménard (21,78 %). La découverte de la masse était fortuite dans 64,36 % des cas. L'examen clinique révélait des palpitations (7,92 %), un faciès cushingoïde (4,95 %) et un excès de poids (47,52 %). Le bilan hormonal montrait un hypercorticisme dans 2,97 % des cas, des métanéphrines élevées (23,76 %), un hyperaldostéronisme (13,86 %) et une élévation du vanylmandélique acide (11,88 %).

Les explorations radiologiques étaient : une échographie surrénalienne (43,56 %), une tomodensitométrie surrénalienne (93,07 %), une imagerie par résonance magnétique surrénalienne (19,80 %) et une scintigraphie à la MIBG (27,72 %). Un traitement chirurgical était indiqué chez 26,73 % des patients. L'examen anatomopathologique concluait à un phéochromocytome (10,89 %), à un adénome de Conn (5,94 %) et à un corticosurrénalome (4,95 %).

Discussion: Nos résultats montrent que la majorité des masses surrénaliennes sont découvertes fortuitement, et que l'évaluation hormonale et radiologique reste déterminante pour orienter la prise en charge chirurgicale.

Conclusion: L'investigation d'une masse surrénalienne doit déterminer si cette dernière est sécrétante, maligne ou bénigne. Les résultats de cette investigation clinique, hormonale et radiologique vont poser l'indication chirurgicale.

ID 1086- Epidemiological and Clinical Profile of Scorpion Envenomation in the Emergency Department of Ibn Jazzar Kairouan

Anna DI GIUSEPPE, Vanessa PALMA, Elodie ROQUETTE

Université De La Réunion, Saint Pierre, France

Context: Depuis cinq ans, l'Université de La Réunion propose une formation d'Éducation Thérapeutique du Patient (ETP) uniprofessionnelle obligatoire, destinée aux internes de médecine générale. À partir de 2025, cette offre évolue vers un dispositif interprofessionnel « UniTEP », réunissant internes de médecine générale, infirmier·ère·s en pratique avancée (IPA), avec ouverture aux étudiant·e·s de Master en activité physique adaptée (APA) poiur 2026. Le programme de 42 heures, animé par deux médecins généralistes, une infirmière et une patiente partenaire, donne lieu à une attestation de formation.

Objectives: Comparer la mise en œuvre de la formation à l'ETP dans les universités et départements de médecine générale, identifier les freins et leviers au développement de dispositifs interprofessionnels et mobiliser l'intelligence collective pour co-construire des stratégies réalistes de dépassement de ces freins.

Teaching method and workshop: L'atelier débutera par une présentation synthétique du cadre actuel d'UniTEP. Les participants travailleront ensuite en groupes pour cartographier leur propre modèle de formation et repérer les difficultés rencontrées. Des diagrammes d'Ishikawa seront dis

Expected outcomes: Les participants découvriront la diversité des modèles de formation à l'ETP, identifieront des priorités d'action et repartiront avec un support de plaidoyer co-produit pour nourrir le dialogue avec leurs tutelles.

Conclusion: Cet atelier vise à optimiser les enseignements d'ETP portés par les équipes pédagogiques et à favoriser l'émergence de cursus plus structurés et interprofessionnels.

(3) Hospital Sahloul, Sousse-Tunisie, Tunisie

Context: Le diabète de type 2 constitue un facteur de risque majeur pour les maladies cardiovasculaires. L'hémoglobine glyquée (HbA1c), reflet du contrôle glycémique à long terme, pourrait représenter un marqueur prédictif du risque cardiovasculaire.

Objectives: L'objectif de cette étude est d'évaluer l'association entre les taux d'HbA1c et la survenue de complications cardiovasculaires chez des patients diabétiques de type 2, afin de déterminer si ce biomarqueur peut servir d'indicateur pronostique.

Methods: Il s'agit d'une étude transversale à visée analytique menée sur 31 patients atteints de diabète de type 2, suivis au service de cardiologie du CHU Sahloul entre février et avril 2025. Les données cliniques, biologiques (HbA1c) et cardiovasculaires (HTA, coronaropathies, etc.) ont été recueillies. L'analyse statistique a été réalisée à l'aide des tests de Student et de Chi² pour explorer l'association entre HbA1c et les événements cardiovasculaires.

Results: L'âge moyen était de 67 ans, avec 61,2 % d'hommes. Le taux moyen d'HbA1c était de 8,07 % ± 1,88. Le score Globorisk moyen était de 1,7 % ± 1,29, avec 51,61 % des patients à risque modéré ou élevé. 13 patients (41,9 %) avaient un taux d'HbA1c ≥ 8,8 %. Au total, 35,48 % ont présenté un événement cardiovasculaire, dont 22 % une cardiopathie ischémique. Une association significative a été observée entre HbA1c ≥ 8,8 % et les événements cardiovasculaires (p = 0,011).

Discussion: Un HbA1c ≥ 8,8 % est fortement associé à la survenue d'événements cardiovasculaires dans notre cohorte.

Conclusion: Un taux élevé d'HbA1c est associé à une augmentation du risque cardiovasculaire, soulignant son utilité pronostique.

(3) Hospitalsahloul, Sousse-Tunisie, Tunisie

Context: L'hypertension artérielle (HTA) est un facteur de risque majeur des complications cardiovasculaires. La mesure ambulatoire de la pression artérielle (MAPA) est aujourd'hui reconnue comme un outil de référence pour le diagnostic, la stratification du risque cardiovasculaire et le suivi du patient sous traitement.

Objectives: Analyser la prévalence et l'impact des anomalies du dipping tensionnel sur la qualité de vie et le pronostic cardiovasculaire de nos patients.

Methods: une étude rétrospective, descriptive et transversale dans le service de cardiologie de l'hôpital universitaire Sahloul de Sousse, entre mars et Février 2025.

Results: Soixante patients ont été inclus. L'âge moyen était de 65 ans avec 60% étaient des femmes. L'HTA concernait 81,7 % des patients, 51,7 % étaient diabétiques. Une bithérapie antihypertensive ou plus était initialement prescrite dans 63,8 % des cas. Les indications de la MAPA étaient le suivi d'une HTA (50 %), l'évaluation du traitement (21,7 %), l'aide au diagnostic (18,3 %), la recherche de variabilité tensionnelle (8,3 %) et la suspicion d'HTA masquée (1,7 %). Un profil non-dipper ou riser a été retrouvé chez 79,7 % des patients. 51,7 % des patients présentaient une HTA nocturne, 65 % un pic matinal et 50,9 % une pression pulsée élevée (> 60 mmHg). La MAPA a permis d'identifier une HTA résistante et un contrôle tensionnel adéquat dans 11,7 % et 35 % des cas respectivement. Ces résultats ont conduit à une modification du traitement chez 60 % des patients : ajout de molécule (41,7 %), changement de classe (16,7 %) ou augmentation de dose. Sur un suivi moyen de 3 mois, des événements cardiovasculaires sont survenus chez 10 % des patients (principalement des syndromes coronariens aigus). La qualité de vie, évaluée chez 38 patients à l'aide du score SF-12, était altérée dans 92 % des cas. Aucune association statistiquement significative n'a été retrouvée entre les profils circadiens et la survenue à moyen terme d'événements cardiovasculaires ou la qualité de vie.

Discussion: La MAPA permet un affinement diagnostique et une adaptation thérapeutique personnalisée, contribuant potentiellement à l'amélioration de la prise en charge et du pronostic.

Conclusion: l'intégration de la MAPA permet d'assurer un suivi rigoureux des patients hypertendus .

ID 1765- Epidemiology of chronic kidney disease in type-2 diabetes patients: a descriptive population-based study

Belhadj Jrad FIRAS [(1)] , Raja GHZEL [(1)], Sameh BEN FARHAT [(2)]

(1) Hospital Kairouan, Sousse-Tunisie, Tunisie
(2) Hospital Sahloul, Sousse-Tunisie, Tunisie

Context: Le syndrome coronarien avec sus décalage de ST (STEMI) est une cause majeure de mortalité nécessitant une prise en charge rapide. En Tunisie, des délais persistants limitent l'efficacité de la revascularisation.

Objectives: Cette revue vise à identifier les complications préhospitalières et les stratégies réduisant les délais afin d'améliorer la survie.

Methods: Pour réaliser cette revue de littérature, nous avons adopté une démarche hybride combinant les approches systématique et narrative afin d'obtenir à la fois une rigueur méthodologique et une interprétation qualitative approfondie. La recherche documentaire s'est étendue sur une période précise (1er–14 juillet 2025), incluant les registres nationaux tunisiens ainsi que la littérature internationale récente.

Results: Le diagnostic du STEMI repose sur un ECG en 12 puis 18 dérivations, idéalement réalisé dans les 10 minutes suivant le premier contact médical, avec une attention particulière aux formes atypiques nécessitant une activation immédiate de la reperfusion. L'évolution peut être rapide vers des complications mécaniques, rythmiques ou hémodynamiques, notamment le choc cardiogénique. L'angioplastie primaire doit être réalisée dans les 90 à 120 minutes : au-delà de 120 minutes, la mortalité atteint 4 %, contre 0 % lorsque le délai est ≤ 120 minutes. Chaque minute supplémentaire entre le premier contact médical et l'admission augmente de 2 % le risque de décès hospitalier. Un délai de reperfusion > 1 h accroît la mortalité à 1 an de 26 %, et > 2 h de 51 %. Les principaux facteurs de décès préhospitalier sont le sexe féminin, les présentations atypiques, le BAV complet, le bloc de branche gauche, l'hypotension et la fibrillation ventriculaire. La mortalité préhospitalière est estimée à 2,1 %, avec un arrêt cardiaque observé chez 5,6 % des patients. Une anticoagulation et une antiagrégation précoces, une prise en charge rapide des complications cardiovasculaires(arythmie , choc)ainsi qu'une coordination en temps réel, améliorent les délais et réduisent la mortalité à 30 jours.

Discussion: Un diagnostic rapide du STEMI ,ECG en ≤ 10 min ,suivi d'une reperfusion mécanique en ≤ 90 min après le premier contact médical réduit la mortalité .

Conclusion: Une coordination des filières de soins est indispensablepour diminuer la mortalité, notamment dans le contexte tunisien.

ID 200- Equitable Healthcare Behind Bars: Challenges and Responsibilities for General Practitioners

Jörg SCHMID

German Climate And Health Alliance (klug), Munich, Allemagne

Context: Exceeding planetary boundaries with climate change and biodiversity destruction poses an existential threat to human health and livelihoods. The concept of planetary health offers a holistic understanding of the complex interrelationships of health and the vitality of planetary systems. Addressing the human impact of global environmental change requires an expansion of the medical ethos and medical practice in the Anthropocene.

Methods: We conducted a non-systematical literature review and argue for the integration of Planetary Health values in considerations of general practitioners's medical ethos and clinical practice.

Originality: The existing frameworks and findings were adapted and applied to primary care and general practitioner's clinical work.

Lessons learned and future implications: The abundance of position papers, reports, and initial measures from professional associations

such as WONCA and EYFDM show a great interest in planetary health values. The challenge will be to develop effective measures and instruments in order to meet the necessary speed in dealing with planetary emergency.

Discussion: In view of the rapidly intensifying planetary crises, swift and courageous action is needed to avert the worst effects of exceeding planetary boundaries and to adapt social structures to the already noticeable and intensifying impacts. The international code of medical ethics by the World Medical Association (WMA) has already included planetary health as a third core value for medical practice, alongside doing no harm and patient autonomy. General practitioners can thus play a key role in communicating and initiating solutions to combat planetary crises. The primary care system can be a driver and beacon in a socio-ecological transformation toward a resilient health care sector and society. More and more actors in the healthcare sector are joining forces to embark on this path.

Conclusion: Further development of general practitioner's self-image and ethos is required with regard to the contribution of the healthcare system to socio-ecological transformation for healthy people on a healthy planet.

ID 334- Equitable Healthcare for Incarcerated Populations: Lessons for General Practice

Assumpta FERRER, Agustina LUJAN, Vanessa OCCHIPINTI, Olin BAZURCO, Valenti RODRIGUEZ, Chirag NANDWANI

Cap El Pla . Ics, Sant Feliu De Llobregat, Espagne

Context: Latent autoimmune diabetes in adults is a form of diabetes recently classified in 2019 by the World Health Organization in 2019 (LADA), frequently underdiagnosed in primary care(PC), with an increasing incidence of 7-14%.

Methods: We describe a 68-year-old male previously diagnosed with type 2 diabetes mellitus (T2DM) three years prior. He presented in PC after two weeks of amnesia, behavioral changes, and sleepiness. Systemic physical examination was unremarkable, leading to referral to the hospital with a differential diagnosis of subacute cerebrovascular disease or frontotemporal disease. During hospitalization, he was diagnosed with autoimmune limbic encephalitis. One month later, follow-up in PC showed marked clinical improvement. Given the possible association with autoimmune processes, LADA was suspected and anti-glutamic acid decarboxylase 65(Anti-GAD65) antibodies, not previously tested at the hospital, were requested. Results revealed HbA1c 6.3%, glucose 140mg/dL, LDL45mg/dL, and Anti-GAD65 45.9 kUI/L (normal ≤4.9), confirming and reclassifying the diagnosis from T2DM to LADA. The patient currently remains active, followed closely in PC, without need for insulin therapy or hospital-based diabetes management.

Originality: We often suspect LADA in our consultations when there is poor T2DM control. However, in this case, in a patient with good metabolic control, the high index of suspicion for coexisting autoimmune syndromes made the diagnosis possible.

Lessons learned and future implications: We also emphasize in this patient the importance of active surveillance from PC. Thus, in an insulin-dependent disease present from its onset in 50-70% of cases3, the early clinical approach in the described case contributed to maintaining good metabolic control from PC and greater pancreatic reserve without the need for insulin therapy. Furthermore, the presence of low levels of GAD autoantibodies, as described in the literature, is associated with a better prognosis for T2DM, as found in the described case.

Discussion: LADA represents a continuum between T1DM and T2DM, and can be diagnosed with an analysis from our consultations, especially when associated autoimmune conditions are present, thereby improving underdiagnosis and prognosis.

Conclusion: LADA is a disease for which a high index of suspicion in PC, especially in the presence of other autoimmune diseases, can improve both underdiagnosis and clinical follow-up for patients.

ID 1369- Equity and Inequity in WONCA Europe Conferences: A Cross-Sectional Analysis of Scientific Themes, 2008–2024

Maxime PAUTRAT

Faculté Médecine, Tours, France

Context: Current guidelines encouraging SBIRT in primary care but do not specify how to deal with addictive disorders, even though patients expect them to do so. In addition, a previous study points out that nurses and physical therapists express a lack of training or legitimacy: they believe that patients will listen less to their advice than to that of a doctor.

Objectives: The aim of this study is to identify the best questions that would enable caregivers to feel confident about discussing addictive disorders with their patients.

Methods: Cross-sectional quantitative study conducted among pharmacists, midwives, nurses, physical therapists and dentists, all recruited in their offices, multidisciplinary primary care health centers, or peer groups on social media, between January and May 2025. Fifteen questions selected from validated tests, translated and reformulated according to health literacy principles, were distributed via an online questionnaire (EVALandGo®). Each participant rated either their ease in asking these questions on a Likert scale (1 to 4). Participants were invited to choose their preferred question. A bonified means, incorporating the frequency of preferences, was used to establish the final ranking.

Results: A total of 160 caregivers responded and identified the following as the most appropriate questions: “Have you ever tried unsuccessfully to reduce or stop a consumption or a behavior? “ (bonified mean = 5,88), “Have you ever had an irresistible craving to consume or do something?” (5,15). The less popular question was "Do your relatives have a problem with your relationships?" (2,44).

Discussion: The test-retest reliability and the impact on the frequency of start talking about addiction in consultation by primary care professionnals helped by these questions have to be evaluate.

Conclusion: By comparing the results of the same study conducted among primary care professionals, the top-2 best questions identified as most suitable to help primary care professionals address addictive disorders are common. Helped by these two questions to start talking about addiction, it could be interesting to assess the appropriation of the SBIRT procedure by primary care professionals.

ID 169- Equity in Care: Barriers to Access and Treatment for Tobacco Use among Racialized and LGBTQIA+ Populations.

Elena POPA, Mihaela POROCH, Monica UNGUREANU, Ana Maria HOLICOV, Agnes-Iacinta BACUSCA, Andrei-Emilian POPA, Elena Adorata COMAN

University Of Medicine And Pharmacy, Iasi, Roumanie

Context: Low-grade chronic inflammation is increasingly recognized as a central contributor to declining fertility in both women and men. Conditions frequently encountered in family medicine—such as obesity, insulin resistance, prediabetes, PCOS, endometriosis, chronic stress and metabolic syndrome—promote a persistent pro-inflammatory state that affects ovulation, oocyte quality, endometrial receptivity and semen parameters. Despite its impact, inflammation-related fertility risk is often under-recognized in primary care, especially in regions with limited access to hormonal testing, metabolic screening and preconception counselling. Significant disparities exist between Eastern and Western Europe, where patients in the East, including Romania, face delayed diagnosis, reduced access to reproductive evaluation and fewer preventive services.

Objectives: To review current evidence linking low-grade inflammation to impaired fertility and to examine how inequities in access to reproductive assessment affect early detection and prevention in family medicine.

Methods: A narrative review was conducted using PubMed, Embase and Scopus (2014–2024). Studies exploring metabolic inflammation, fertility outcomes, reproductive endocrinology and primary care approaches were included.

Results: Low-grade inflammation alters reproductive physiology through cytokine imbalance (IL-6, TNF-α), oxidative stress, endothelial dysfunction and endocrine disruption. These mechanisms correlate with anovulation, reduced oocyte competence, impaired implantation and decreased sperm quality. While Western European countries benefit from early metabolic screening, routine preconception counselling and timely fertility referral within primary care, Romania continues to face marked limitations in these areas. Access to metabolic evaluation is frequently delayed, reproductive hormone testing is inconsistently available in family medicine, and structured preconception pathways remain largely absent. As a result, early reproductive risk factors associated with low-grade inflammation are often recognized late, contributing to delayed diagnosis of subfertility and poorer preventive outcomes compared with Western Europe.

Discussion: Integrating inflammation-focused assessment into routine family medicine—through early metabolic screening, lifestyle interventions, menstrual cycle evaluation and male fertility assessment—can significantly reduce the progression toward infertility. Closing the East–West access gap requires equitable pathways, improved availability of diagnostic tools and strengthened preconception services.

Conclusion: Low-grade inflammation is a modifiable determinant of fertility decline. Enhancing equity in access to metabolic screening, reproductive evaluation and preventive counselling within family medicine is essential to improving fertility outcomes and reducing disparities across Europe.

ID 947- Escape room in person-centered anamnesis for suspected pregnancy in adolescent primary care

Yoonsoo SUNG, Sung SUNWOO

Department Of Family Medicine, Ulsan University College Of Medicine, Seoul, Corée (République de)

Context: Self-rated health (SRH) is crucial for predicting morbidity and mortality across age groups, including adolescents and adults. Body image dissatisfaction, measured by difference between current and ideal weight, surpasses Body Mass Index (BMI) in predicting health outcomes. We evaluated the correlation between body image perception and SRH among middle and high school students in Korea.

Objectives: This study used data from the 2022 Korea Youth Risk Behavior Web-based Survey (KYRBS), conducted by the Korea Disease Control and Prevention Agency between August 29 and October 25, 2022. The KYRBS is an annual, nationwide survey of students from the first year of middle school to the third year of high school.

Methods: Subjective health status was categorized into 'good' or 'poor' groups. Body image was classified into 'underweight,' 'normal,' or 'overweight'. BMI was determined using age-specific percentiles: underweight (<5th), overweight (85th-95th), and obese (>95th). Data analysis was performed by multivariable logistic analysis and adjusted for depressive mood, stress, and socioeconomic status. All analyses were performed using SPSS Statistics version 27.0 (IBM Crop. Armonk, NY, USA).

Results: The total participants (N=50,455) included 59.4% with normal weight according to BMI, only 36.4% perceived themselves as normal. Students who perceived themselves as having a normal weight had higher rates of good SRH compared to others. Excluding females with BMI ≥25kg/m², both genders

showed higher odds ratios for poor SRH when perceiving themselves overweight (Male: OR 2.57, 95% CI 2.367 – 2.782; Female: OR 1.36, 95% CI 1.270 – 1.452) or underweight (Male: OR 1.64, 95% CI 1.507 – 1.791; Female: OR 1.36, 95% CI 1.256 – 1.472).

Discussion: This study is meaningful in that it examined the relationship between body image perception and self-rated health using large-scale, nationally representative data. Self-rated health is known to be one of the strongest predictors of healthcare utilization, medical costs, and mortality, and poor self-rated health in adolescence has been reported to influence health outcomes in adulthood.

Conclusion: More than half of the students responded negatively to their body image, associated with poor subjective health status. Therefore, promoting accurate body weight perceptions will play a positive role in overall health of adolescents.

ID 807- Esophageal candidiasis while immunocompetent: a case report

Xavier HUMBERT, Alizée BUENO

Université Caen Normandie, Caen, France

Context: Feared since ancient times for its sudden and unpredictable nature, sudden death remained medically poorlyunderstood at the beginning of the 20th century. A striking phenomenon due to its unexpected nature, it was frequently reported in the local press, where approximate medical explanations and social representations intersected.

Objectives: The aim of this study is to analyze the socio-medical representations of sudden death in newspapers in the Domfront district between 1900 and 1914.

Methods: A case study was conducted based on two regional weekly newspapers (Le Courrier de Flers and L'Echo de la Ferté-Macé). Cases explicitly described as "sudden death," "natural death," or reported as sudden deaths with no identified external cause were included. Each case was coded according to age, sex, occupation, season, and reported causes.

Results: A total of 181 cases were identified. The majority involved men over the age of 50, most of whom were engaged in physically demanding occupations, particularly agriculture. Deaths were more frequent in autumn and winter. The medical terms used were mainly "congestion" and "apoplexy." Cold weather and alcohol were regularly cited as triggering factors.

Discussion: This study highlights a phenomenon that was common but medically poorly defined, even for practitioners at the time. The journalistic treatment of sudden death reflects both the limitations of medical knowledge and the influence of social and religious representations, with the press reporting these deaths in the news in briefs section.

Conclusion: Beyond historical aspects, the epidemiology of sudden death has changed relatively little since the early 20th century. Cardiovascular risk factors have been identified since the mid-1950s. However, greater attention is now being paid to women's cardiovascular health. Psychosocial factors also remain relevant in general medicine, as sudden death continues to be a traumatic event due to its suddenness, requiring appropriate support for loved ones that goes far beyond religious considerations.

ID 154- Essential but Overlooked: The Global Story of Immigrant Clinicians in the XXX Primary Care Workforce

Xavier HUMBERT

Université Caen Normandie, Caen, France

Context: Office white-coat effect tail (OWCET), the waning of blood pressure after its wax during office visit, predicted long-term major fatal and non-fatal cardiovascular events. Data on the long-term reproducibility of OWCET are scare.

Objectives: The aim was to examine the long-term reproducibility of OWCET in the Gubbio residential population study (Gubbio, Italy) after approximately 5.8 years follow-up.

Methods: To determine the presence of OWCET, three measures of blood pressure separated by one minute each was involved . If the first measure is at least 10 mmHg greater than the third measure, we consider a presence of OWCET. We used a cohort study realised in Gubbio, an Italian city. It started in 1983 and contains a first serie of data collection, during appointments, as well as a second one between the years 1989-1992. Studying the reproductibility of OWCET boils down to evaluating the existence of a dependance between the presence/absence of a OWCET during the first appointment and the presence/absence of a OWCET during the second appointment in the same individual. In order to measure the strength of the reproductibility of OWCET, we will use the Cohen's kappa statistic.

Results: The raw rate of reproductibility in the 1 300 individuals sample is 72.69%. : 907 (69.77%) individuals did not present a OWCET during either appointments ; 38 (2.92%) individuals presented a OWCET during both appointments ; 148 (11.38%) individuals presented a OWCET during the first appointment but not the second one and 207 (15.92%) individuals presented a OWCET during the second appointment but not the first one. For the sample of 1 300 individuals of age between 35 and 74, the kappa statistic is equal to 0.016 (95%CI: -0.039;0.071).

Discussion: In our knowledge, it is the first time that long-term reproducibility of OWCET was tested. Others BP concept reproducibility was studied in the past with the same poor reproducibility.

Conclusion: OWCET display poor reproducibility over time. This should be taken into account in studies assessing the long-term prognostic value of these conditions based on only one set of BP measurements, in particular in primary care.

ID 1205- Ethical and legal dimensions of biohacking for astronauts' health in long-duration space missions: A literature review for primary care

Xavier HUMBERT

Université Caen Normandie, Caen, France

Context: Potential link between proton pump inhibitors (PPIs) and hypertension remains unclear. It is uncertain whether such an association exists, whether it represents a class effect, and whether a dose-response relationship is involved.

Objectives: We aimed to investigate the potential class effect associating PPIs with hypertension reporting, and evaluate whether the association follows a dose-dependent pattern.

Methods: We conducted a disproportionality analysis within VigiBase® to identify signals of hypertension reporting associated with individual PPIs by calculating adjusted reporting odds ratios (aRORs) within a multivariate case/non-case study design. Additionally, we explored the presence of a dose-response relationship. We utilized real-world data from VigiBase®, the World Health Organization (WHO) pharmacovigilance database. We identified that incident hypertension cases using the Medical Dictionary for Regulatory Activities V.26.1 related with at least one PPI administration were systematically collected until October 28th, 2024. Pharmacovigilance signal between PPIs use and hypertension reported and dose dependence between PPIs posology and onset or worsening hypertension were explored.

Results: The database contained 26,587 reports of PPI-associated hypertension (2.3%), predominantly among women (63.3%). Hypertension was most frequently reported in the age group of 45-64 years (41.4%). A significant reporting odds ratio (ROR) was observed for almost all PPIs in both univariable (RORs ranging from 1.33 to 1.98) and multivariable analyses (aRORs ranging from 1.15 to 1.31) after adjustments for age group, sex, concurrent antihypertensive medication, and drugs known to induce hypertension, with

the exception of lansoprazole (aROR: 0.95). A potential trend suggestive of a dose-response relationship was identified, with doses lower than the median associated with a lower aROR for hypertension compared to doses higher than the median for all PPIs. However, this trend did not reach statistical significance, likely due to insufficient statistical power.

Discussion: This investigation, conducted under real-life conditions, unveils a notable pharmacovigilance safety signal associating PPI usage with hypertension reporting.

Conclusion: While a potential dose-response trend was observed, it did not reach statistical significance, possibly due to limited statistical power. Further longitudinal studies are warranted.

Context: Mentoring programme of the College of GPs of XXX initiated by the Faculty of Teachers of CGPSL in 2012. In 2022 Annual Academic Sessions the College Oration was based on the Mentoring Programme . The CGPSL mentor pool consists of 67 well trained mentors who have undergone the “Mentorship Training Programme”, which mainly consists of mentoring workshops held annually to update their knowledge. Additionally the mentors engage in several assessments related to the MCGP course and some are also members of the MCGP Board of Study and of the examiner pool of the MCGP programme. The Mentoring Programme of the College consists of the following: 1. General Practice mentoring 2. MCGP Programme mentoring 3. Membership mentoring The MCGP programme is one of the unique professional post graduate courses in XXX where the facility of a mentor is offered to a trainee. It is a PG course for the practicing GPs and recognized by XXX Medical Council. MCGP mentoring helps the MCGP trainee to follow the course in a focused and organized manner and guides them through the two year course and afterwards . The MCGP mentor plays a

major role in guiding the trainee in preparing the Assessment Portfolio, which is an important component of the MCGP Programme. The General Practice mentoring is offered to any doctor wanting to set up a practice, on request, by CGPSL to ensure quality of patient care by a young doctor at the inception of his practice. The membership mentoring is offered to those who have applied for CGPSL membership and obtained approval by the council. They undergo a mentoring programme for one month under a senior mentor before obtaining the membership of the College. The CGPSL Mentoring Committee was invited as advisors to launch the Academic Mentoring Network programme for all the other Medical Professional bodies in 2021.

Methods: Categorisation and evaluation of the Mentoring Programme

Originality: It is an ongoing programme.

Lessons learned and future implications: Value of Mentoring

Discussion: The benefit of having a Mentoring programme in a Family Medicine PG Education Programme

Conclusion: Concept of Mentoring is an essential component in any PG Training Programme

Sangam Surgery, London, Royaume-Uni

Context: NICE recommends women who were diagnosed with gestational diabetes and whose blood glucose levels returned to normal after the birth: offer lifestyle advice (including weight control, diet and exercise. After 13 weeks offer a fasting plasma glucose test or an HbA1c test if a fasting plasma glucose test is not possible

Methods: Methods : 40 patients notes were retrospectively reviewed by giving random numbers out of 133 patients.

Originality: Aim : To assess BMI and HbA1c was ordered or carried out at postnatal review as per guidelines by 13 weeks after delivery . To assess BMI was calculated for prevention of obesity related disorders

Lessons learned and future implications: Results : 49% patients had Hba1c completed and reviewed as per guidelines. 58% patients had BMI calculated at postnatal check. The mean BMI was 29.7 +/-4.4 kg/m2.

Discussion: Our patients are mainly ethnic minority immigrant group where there is high prevalence of Type2 diabetes. This project showed we need to improve our monitoring of gestational diabetes review to prevent future diabetes and obesity related disorders.

Conclusion: We have introduced warning messages in patients records as reminder for clinicians We had a training for monitoring/coding team to order blood test and use text messages as reminder for patients. ID 398- Evaluating Melatonin Use for Insomnia in Primary Care: A Literature Review and Survey of Family Physicians

Hweesoo JEONG

Dongguk University, Medical School, Ilsan, Gyeonggi-Do, Corée (République de)

Context: The phase angle score is an indicator of induced resistance measured in bioelectrical impedance analysis (BIA), with lower values indicating decreased cellular function. Currently, the clinical application of the phase angle score is to assess nutritional status, sarcopenia, and prognosis in high-risk patients, as well as cancer patients.

Objectives: This study was conducted to confirm the relationship between the phase angle score and risk factors of cardiovascular disease.

Methods: This study is a cross-sectional study using 16,009 subjects whose phase angle scores were measured among the raw data of the 9th Korea National Health and Nutrition Examination Survey (2022-2023). After dividing the entire subjects into males and females and excluding subjects with missing values for study variables and subjects taking medication for hypertension, diabetes, and hyperlipidemia, the final analysis subjects were 3,280 men and 3,961 women. The correlation between age, systolic blood pressure (SBP), diastolic blood pressure (DBP), weight circumference, Body Mass Index (BMI), fasting glucose, HbA1c, total cholesterol, HDL-cholesterol, triglyceride (TG), LDL-cholesterol, hsC-reactive protein (CRP), and Serum Vitamin D3 and phase angle score was confirmed.

Results: In male subjects, a low phase angle score was associated with old age (Coefficient=-0.164, p<0.01), low BMI (0.139, p<0.01), high HbA1C (-0.064, p=0.016), high waist circumference (-0.035, p<0.01), high hsCRP (-0.005, p=0.026), and low serum. Vitamin D3 (0.005, p<0.01), high SBP (-0.005, p<0.1), low DBP (0.006, p<0.01), low fasting glucose (0.002, p=0.019), and low TG (0.001, p=0.017). In female subjects, low phase angle score was associated with low BMI (0.068, p<0.01), high weight circumference (-0.009, p<0.01), old age (-0.008, p<0.01), high SBP (-0.005, p<0.1), low DBP (0.007, p<0.01), low total cholesterol (0.004, p=0.008) and low serum vitamin D3 (0.002, p=0.005).

Discussion: In both men and women, low phase angle scores were commonly associated with older age, lower BMI and waist circumference, higher systolic and lower diastolic blood pressure, and lower serum vitamin D3. In men, they were particularly associated with higher HbA1C and higher hsCRP.

Conclusion: The phase angle score is associated with cardiovascular disease risk factors. In clinical practice, the phase angle score can also be used to predict cardiovascular disease.

(1) Department Of Wellness, Nepal Mediciti Hospital, Lalitpur, Népal
(2) Department Of Pulmonology And Critical Care, Tribhuvan University Teaching Hospital, Institute Of Medicine, Kathmandu, Népal

Context: Dengue has rapidly expanded in XXX affecting all 77 districts. It was first reported in 2004 in XXX, a tropical, lowland district. Climate change has resulted in geographic expansion of Dengue with cases reported from higher altitude and mountainous regions. Since COVID-19 pandemic in XXX, sporadic cases of co-infection with Dengue have been reported raising significant public health concern.

Objectives: This study aims to investigate clinical, laboratory and epidemiological features of Dengue-COVID-19 co-infection at tertiary hospital located in temperate climate region in a low- and middle-income country.

Methods: A cross-sectional study was conducted during July to October 2023 among patients testing positive for Dengue (via NS1 antigen and/ IgM antibody). SARS-CoV-2 reverse-transcriptase polymerase-chain reaction (RT-PCR) was assessed in same cohort who developed symptoms of COVID-19. In-hospital patient records were used for data collection. Patient demographics, clinical features and laboratory findings were analyzed.

Results: Total 62 Dengue positive patients were admitted among which SARS-CoV-2 RT-PCR was positive in 33 (53.2%) patients. Mean age was 42.56±17.32 years. There were 54.8% male. Among co-infection cases, majority presented with fever (87.9%), myalgia and joint pain (87.9%), cough (27.3%), headache (90.9%) and gastrointestinal symptoms (45.5%). Laboratory results revealed overlapping markers like thrombocytopenia (90.9%) and leucopenia

(51.5%). Co-infection was associated with higher risk of complications, longer hospital stay and death compared to mono-infection.

Discussion: The emergence of Dengue-COVID-19 co-infection in temperate region of XXX reflects the evolving epidemiology of climate-sensitive diseases; as rising temperatures enable Aedes mosquitoes to inhabit higher altitudes likely facilitated by climate change. Our findings support this geographic shift with more than half of Dengue positive patients also testing positive for SARS-CoV-2 indicating simultaneous community transmission. The overlapping clinical and laboratory features in Dengue-COVID-19 co-infection made the diagnosis challenging. These findings highlight the need for strengthened surveillance, improved diagnostic capacity and preparedness for emerging co-infections in regions newly affected by Dengue.

Conclusion: This study highlights significant public health threat posed by emergence of Dengue-COVID-19 co-infection in temperate region due to climate change. As Dengue continues to expand to higher altitude, climate-sensitive disease surveillance should be strengthened in these regions.

Rahma SAKKA [(1)], Yassine MAALEJ [(2)]

(1) Family Medecin Trainee, Sfax, Tunisie
(2) General Surgery Consultant, Tataouine, Tunisie

Context: Superficial vein thrombosis (SVT) has regained its place among the venous thromboembolism (VTE) pathology, as a clinical entity, not a benign condition we once neglected. Current evidence demonstrates that SVT can be the initial manifestation of underlying thrombophilia, particularly in cases with recurrent presentation.

Methods: We present the case of a 25-year-old female who consulted with left lower limb SVT. Initial management included 3-month anticoagulation and compression therapy. After 8 months, A recurrent SVT occurred, so a thrombophilia screening was performed, revealing a Factor V Leiden homozygous mutation. These findings have indicated a long-term anticoagulation.

Originality: This case presented SVT as the first and sole manifestation of homozygous Factor V Leiden mutation, highlighting the importance of thrombophilia screening in young patients with recurrent SVT and challenging the traditional view of SVT as a benign condition. Besides, it demonstrates the importance of long-term anticoagulation in a high-risk thrombophilic patient with direct oral anticoagulation as an approved option.

Lessons learned and future implications: This case highlighted the importance of thrombophilia screening within young patients presenting with unexplained or recurrent SVT. The Homozygous Factor V Leiden mutation represents a severe thrombophilic state requiring aggressive management with Long-term anticoagulation. Future implications suggest updating guidelines for thrombophilia screening in recurrent SVT, individualizing anticoagulation strategies based on thrombophilia severity, and enhancing awareness about SVT as a potential indicator of severe thrombophilia.

Discussion: Activated Protein C Resistance (APC-R), primarily caused by the Factor V Leiden (FVL) mutation, creates a hypercoagulable state. Once considered benign, Superficial Vein Thrombosis (SVT) is now recognized as a significant manifestation of this thrombophilia, especially in recurrent cases. The VTE risk is linked to FVL zygosity, with homozygotes facing a 50-100 fold increased risk. Consequently, guidelines recommend thrombophilia screening for recurrent or idiopathic SVT. For high-risk patients, such as those with homozygous FVL, long-term anticoagulation is justified.

Conclusion: SVT can represent the initial clinical manifestation of severe inherited

thrombophilia. Appropriate evaluation and long-term management are crucial in high-risk patients, particularly those with homozygous Factor V Leiden mutation. This case underscores the importance of maintaining clinical suspicion for underlying thrombophilia in recurrent SVT and adopting individualized anticoagulation strategies based on thrombotic risk assessment.

ID 891- Evaluation of limited health literacy among diabetic individuals following intervention with a diabetic nephropathy educational video

Isabela Espíndola ESPÍNDOLA, Ana Vitória CASTRO

School Of Medicine, São Leopoldo Mandic, Araras, Brésil

Context: The postpartum period is a vulnerable phase when physical complications, breastfeeding difficulties, emotional needs and social factors affect maternal and neonatal health. In XXX, primary care recommends the first postpartum consultation within 42 days; when performed at home it enables a contextualized assessment. This report describes a home visit five days after a cesarean delivery, showing how the household uncovers clinical, emotional and social issues often missed in clinic-based care.

Methods: This report stems from a supervised primary care activity carried out by two fourth-year medical students with support from a community health worker. The visit focused on maternal recovery and the family's adjustment to the postpartum period. The assessment included lochia, uterine involution and the surgical wound, along with newborn conditions, breastfeeding technique, mother-infant bonding, family dynamics, social support, housing conditions and barriers to self-care. Field notes were used to compare the information gathered at home with what is typically accessible in clinic-based consultations, showing that the household setting offers a more detailed understanding of maternal and family needs.

Originality: Although home visits are recommended in primary care, few structured reports describe their concrete contribution to postpartum care. This experience shows how the home setting uncovers key social determinants; such as childcare burden, emotional vulnerability, partner support and logistical barriers; that often remain unnoticed in clinic-based encounters. The community health worker's involvement strengthened rapport, communication and continuity of care.

Lessons learned and future implications: This experience highlighted the importance of postpartum home visits as a routine primary care practice. Observing the family environment allowed earlier identification of needs and risks and supported more tailored, context-sensitive interventions. Strengthening this approach may improve maternal support, continuity of care, and equity in the postpartum period.

Discussion: The home visit broadened the understanding of postpartum health by revealing clinical, emotional, and social factors often overlooked in clinic-based care. This context-based assessment demonstrated the strengths of community-oriented primary care and showed how proximity to the family environment improves the relevance and effectiveness of postpartum follow-up.

Conclusion: The postpartum home visit proved essential for comprehensive and equitable care, identifying determinants often missed in clinic-based consultations and strengthening maternal support within the family's daily environment.

ID 291- Evaluation of the level of integration and current status of operation of the integrated medical curriculum: a study focusing on the cardiovascular system course

Maryam ZAINA

Primary Healthcare, Ras Al Khaimah, Émirats Arabes Unis

Context: Upper respiratory tract infections (URTIs) are among the most common reasons

for primary care visits. Most URTIs are viral, yet antibiotics are frequently overprescribed, contributing to antimicrobial resistance. This case series highlights real-world prescribing patterns in general practice and emphasizes judicious antibiotic use.

Methods: Six anonymized cases of URTI seen in general practice were collected. Data included patient age, symptoms, diagnosis (viral vs. bacterial), antibiotic prescription, and outcome

Originality: This case provides real-world evidence of appropriate antibiotic prescribing for viral and bacterial URTIs in general practice, highlighting effective stewardship and contributing to the prevention of antimicrobial resistance.

Lessons learned and future implications: This case series reinforces the importance of differentiating viral from bacterial URTIs in primary care to avoid unnecessary antibiotic use. This practice could improve prescribing practices and reduce antimicrobial resistance in broader clinical settings.

Discussion: This case series demonstrates that most URTIs in primary care are viral and do not require antibiotics. Appropriate prescribing reduces unnecessary antibiotic exposure and minimizes the risk of antimicrobial resistance. The cases highlight the importance of differentiating viral from bacterial infections and suggest that real-world audits of prescribing patterns can reinforce guideline-based practice and improve patient outcomes."

Conclusion: Judicious antibiotic use in URTI management is essential. Case-based audits in general practice help reinforce guidelines, optimize patient care, and minimize the development of antimicrobial resistance.

ID 2218- Evaluation of The Prevalence of Cardiometabolic Disorders and Related factors in the Elderly in Southeast of Iran: A Mixed Method study

Eunju PARK

Department Of Family Medicine, Pusan National University Yangsan Hospital, Yangsan-Si, Corée (République de)

Context: In countries where hospice and palliative care (HPC) services are still developing and utilization remains limited, undergraduate curricula are crucial for shaping future physicians' approach to end-of-life care. There is a need to understand how training influences medical students' concept of a good death, their experience of team-based care, and their openness to HPC-related careers.

Objectives: To evaluate whether an integrated HPC curriculum within a family medicine clerkship can: (1) reshape medical students' concept of a good death, (2) enhance HPC knowledge and referral attitudes, and (3) increase consideration of HPC as a future career option.

Methods: A prospective single-group pre-post study was conducted among 50 fourth-year medical students at Pusan National University Yangsan Hospital in South Korea. During a 2-week family medicine clerkship, students received lectures on HPC principles, observed interdisciplinary team meetings and ward rounds in the hospice-palliative care unit, and participated in reflective Q&A sessions. Validated questionnaires were administered before and after the clerkship to assess perceptions of a good death (intimacy, clinical symptoms, personal control), HPC knowledge, attitudes toward referral, and interest in an HPC-related career.

Results: Overall scores for the perception of a good death remained stable; however, the intimacy domain increased (29.12 to 29.94/36, p=0.029), while the clinical symptoms domain decreased (13.50 to 12.64/20, p=0.002), suggesting a shift toward a more relationship-centered yet realistic view of end-of-life care. HPC knowledge improved (12.06 to 13.06/20, p=0.003). The mean score reflecting consideration of an HPC career rose from 26.06 to 36.48 out of 100 (p<0.001). Students rated interdisciplinary team meetings as the most influential component, followed by ward rounds.

Discussion: The curriculum reshaped students' understanding of a good death and strengthened their readiness to engage with HPC. Experiential, team-based activities appeared more impactful than didactic elements in promoting attitudinal and professional changes.

Conclusion: Embedding structured HPC training within a family medicine clerkship can foster a relationship-centered, team-based understanding of a good death and strengthen the future workforce pipeline for palliative care. These findings support using family medicine clerkships as a strategic platform for HPC education and primary palliative care capacity-building in settings where services are still developing and utilization remains suboptimal.

ID 1958- Evaluation of the relationship between professional quality of life and smartphone addiction among family medicine residents

Ciara STEELE

Icgp, Buncrana, Irlande

Context: Training effective lifelong practitioners is crucial to any healthcare system. Pressures on GP trainees have increased and include burnout as an occupational risk. To prevent attrition, focus on mitigation at an early stage in training has been recommended.

Objectives: To investigate the efficacy of a pilot curriculum based mindfulness reflection and resilience program for GP Registrars

Methods: GP trainees were invited to attend 4 morning sessions and one retreat day which was integrated into the curriculum. Volunteers from the intervention group were invited to join a discussion forum aimed at exploring experiential learnings in greater depth. Qualitative data gathered from the focus group was analysed using thematic analysis to identify common themes and insights.

Results: The focus group identified a number of themes including quality of cross specialty program delivery and content, the experience of a safe space, the relevance of content, the uptake of mindfulness skills and the impact of these skills on stress management. Challenges to sustainable practice were also identified.

Discussion: Burnout among medical professionals is common at all stages. Occupational stress and exposure to human pain and suffering predisposes medical professionals to this condition. Taking steps to manage these stressors and sustain personal psychological health should be proactive and provided for in training.

Conclusion: Medical Students are at high risk of psychological distress, depression and suicidality. The health and well- being of doctors is key to supporting the quality and safety of patient care. Educational bodies are ideally placed to support resiliency programs.

Merve ERTOP ÇOLAK

University Of Health Sciences, Atatürk Sanatorium Training And Research Hospital, Department Of Family Medicine, Ankara, Türkiye, Ankara, Türkiye

Context: Equitable prevention of Type 2 diabetes requires attention to behavioral and lifestyle factors that influence health. Eating behaviors, as modifiable determinants, offer an opportunity for patient-centered and humanistic interventions in primary care.

Objectives: This study aimed to investigate the relationship between eating behaviors and the risk of developing Type 2 diabetes among adults.

Methods: This cross-sectional and descriptive study was conducted between 15 June and 15 September 2024 at the Family Medicine Outpatient Clinic of SBÜ Atatürk Sanatorium Training and Research Hospital. Non-diabetic adults aged 18–65 years were included, while individuals with diabetes, psychiatric disorders, or diagnosed eating disorders were excluded.

Participants completed a Sociodemographic Information Form, the Finnish Diabetes Risk Score (FINDRISK), and the Adult Eating Behavior Questionnaire (AEBQ).

Results: A total of 272 participants (mean age: 41.3 ± 12.0) were included. Participants were grouped as normoglycemic or prediabetic based on glycemic status. Significant differences were found between the groups in age, body weight, and waist circumference. AEBQ "Hunger" and "Emotional Overeating" scores were significantly higher in the prediabetic group compared with the normoglycemic group. Conversely, the "Slowness in Eating" score was higher among normoglycemic individuals. Several AEBQ subdimensions showed significant correlations with 10-year Type 2 diabetes risk scores. According to FINDRISK classification, individuals in the "High/Very High Risk" category had higher "Hunger" and "Emotional Overeating" scores and lower "Slowness in Eating" scores. The predictive capacity of AEBQ for identifying prediabetes was compared with FINDRISK.

Discussion: Emotional eating, external eating, and rapid eating behaviors were identified as important behavioral factors associated with increased risk of Type 2 diabetes. These results support existing evidence that eating behavior patterns contribute meaningfully to metabolic risk. Incorporating eating behavior assessment into routine primary care evaluations may improve early identification of at-risk individuals and support preventive strategies.

Conclusion: Promote early identification of high-risk individuals by integrating FINDRISK into routine primary care. Expand psychological support programs addressing emotional eating. Encourage physical activity through community campaigns. Develop targeted preventive interventions for high-risk groups, especially women and older adults. Support healthy eating through individualized plans emphasizing high-fiber, low–glycemic index foods, structured meals, slower eating, and portion control.

ID 1157- Evidence-based suturing techniques for primary and emergency care

Mahmud OMAR [(1)] , Shelly SOFFER [(1)], Agbareia REEM [(2)], Glicksberg BENJAMIN [(1)], Charney ALEXANDER [(1)], Nadkarni GIRISH [(1)], Klang EYAL [(1)]

(1) Icahn School Of Medicine At Mount Sinai, New York, États-Unis
(2) Ophthalmology Department, Hadassah Medical Center, Jerusalem, Israel, Jerusalem, Israël

Context: Large language models (LLMs) are increasingly used in clinical decision support. Their recommendations may vary by socio-demographic descriptors, which can influence pain care. These variations may create safety concerns, especially when the model assigns high risk while also recommending high-risk treatments.

Objectives: To measure whether LLM-generated pain-management recommendations differ across socio-demographic groups, and to examine whether models apply inconsistent reasoning when assigning opioid recommendations and risk assessments.

Methods: We evaluated ten widely used LLMs using 1,000 acute-pain clinical vignettes. Each vignette had two versions (cancer and non-cancer pain) and was iterated across 34 demographic categories, including a control version with no demographic information. In total, the models produced 3.4 million responses. For each response, we extracted recommendations on opioid use (yes/no and dose level), anxiety treatment, perceived psychological stress, risk scores, and need for monitoring. We used logistic and linear mixed-effects models to test differences between demographic groups.

Results: Across all models, historically marginalized groups—especially individuals described as Black, LGBTQIA+, or unhoused—received more frequent and stronger opioid recommendations in both cancer and non-cancer pain scenarios. In cancer scenarios, some groups received opioid recommendations in more than 90% of cases. At the same time, these same groups were often labeled as "higher risk" and assigned

elevated monitoring or concern scores. The direction of recommendations and the risk scores did not align. Conversely, low-income and unemployed groups often received higher risk scores but fewer opioid recommendations. Patterns in anxiety treatment and psychological stress ratings also varied across groups, despite identical clinical information.

Discussion: LLMs showed systematic and conflicting patterns: they sometimes recommended high-risk analgesics while simultaneously labeling the same patient profile as high risk for misuse or harm. This inconsistency suggests a reasoning problem rather than a simple bias in one direction. These patterns do not reflect guideline-based practice and may lead to unequal or unsafe care if used in clinical settings.

Conclusion: LLM-generated pain-management recommendations vary across socio-demographic groups and sometimes contain conflicting reasoning. These patterns pose potential safety risks. Routine evaluation of LLM behavior and alignment with established pain-care guidelines is needed before clinical deployment.

ID 1265- Evolving Digital Health Training Needs for the Modern Primary Care Physician: An International Focus Group Study

Celine Anne ESPINA

Governor Celestino Gallares Memorial Medical Center, Tagbilaran City, Philippines

Context: Burnout is exhibited as emotional exhaustion, depersonalization and reduced personal accomplishment, which impacts healthcare workers, leading to occupational hazards such as absenteeism and presenteeism. Understanding these relationships is essential in establishing proactive strategies to enhance employees' well-being. The rise in sickness absences among staff of Gov. Celestino Gallares Memorial Medical Center (GCGMMC) prompted this study.

Objectives: The study aimed to determine the association between workplace burnout, sickness absenteeism and presenteeism among staff of GCGMMC.

Methods: A cross-sectional observational study was conducted at GCGMMC using proportionate stratified random sampling method to select 304 participants from 1449 employees based on a 95% confidence level. Maslach Burnout Inventory-Health Services Survey was used to measure burnout levels and the World Health Organization's Health and Work Performance Questionnaire measured absenteeism and presenteeism.

Results: Seventy-five percent of GCGMMC staff reported workplace burnout with no significant difference (p=0.111) across services. It was highest among staff of Allied Health Professionals (87.9%), Hospital Operations and Patient Support Services (82.4%) and the Medical Service (78.0%). Single (p=0.013), non-permanent (p=0.001) and college level employees (p=0.017) experienced significantly higher burnout rates and were significantly associated with lower absolute presenteeism and higher relative absenteeism.

Discussion: This study explores the relationship between workplace burnout, sickness absenteeism, and presenteeism among staff of GCGMMC.

Conclusion: Data showed that burnt-out employees are more likely to take time off when sick, accumulate greater exhaustion at work leading to increased leave of absence. The reduced productivity at work is an issue from across services affecting burned-out and non-burned-out employees.

ID 1541- Expanding the medical ethos in primary care: integrating planetary responsibility

Sky Wei Chee KOH

National University Polyclinics, National University Health System, Singapore, Singapore, Singapour

Context: As XXX adopts a population health approach under XXX programme, optimizing healthcare resources is crucial.

Objectives: We examined referral reasons (using large language models [LLM]), wait times, and analyse factors affecting referrals from primary to tertiary care.

Methods: In 2023, 1,063,646 patient visits from seven primary care clinics in XXX were analysed. Patient demographics, clinic, physician characteristics, referral volumes and wait times were extracted. LLM Claude 3.5 Sonnet was utilized to identify and classify top referral reasons within the most frequently referred specialties based on referral notes. Chi-square tests identified differences in referral rates among categorical variables, while a generalised linear model (GLM) with an identity link (normal distribution) determined factors influencing referrals by physicians.

Results: Around 1 in 5 visits resulted in a referral (n=210,839, 19.8%), achieving 76.0% attendance rate. Referrals peaked among patients aged 60–70 years. Male (Odds ratio [OR] 0.88, 95% Confidence interval [CI] 0.87-0.89) and Malay (OR 0.71, 95% CI 0.70-0.72, compared with Chinese) patients were less likely to be referred. Significant variations were observed among clinics ($p<0.001$). Ophthalmology (11.1%), orthopaedic surgery (10.3%), and emergency (10.0%) were the most referred specialties, with blurred vision (n=7,461), abnormal diabetic retinopathy screening (n=5,266) and pregnancy and antenatal care (n=3,959) being the top referral reasons. 51.5% were routine referrals. Wait time averaged 52.7 days with 48.9% meeting targets, with long wait times for Gastroenterology & Hepatology, and Endocrinology. On average, each additional year of physician experience was associated

with a reduction of 4.45 referrals per physician (95% CI: 1.40-7.58, p=0.005).

Discussion: Findings support strategies under XXX programme to manage patient volume, strengthen continuity, expand open-access pathways, and enhance decision support to optimize referral appropriateness and timeliness. Key limitations include unmeasured confounders (e.g., socioeconomic status, comorbidity), exclusion of private GP, ED, and inter-specialty referrals, reliance on free-text reasons, possible selection bias, and observational design, warranting further research (including clinic-level factors and qualitative work).

Conclusion: Our study highlighted disparities in referrals rates, patterns, and wait times. Continuing education and support for primary care is paramount. Resource allocation should be tailored to meet the population needs, with further research needed to ensure timely and appropriate referrals.

ID 923- Expériences et représentations des médecins généralistes concernant le dépistage organisé des cancers chez les patients présentant des troubles psychiatriques sévères : une étude qualitative

Ruth OBAYEMI, Tina ARDON, Amy SEEGMILLER

Department Of Family Medicine, Mayo Clinic, Jacksonville, Fl, États-Unis

Context: The US is the only high-income country without national paid parental leave (PPL) laws.The national average for PPL is about 6-8 weeks, compared with the global standard of 18 weeks. In 2018, the ACGME added lactation support provisions to their basic requirements for training programs; however, awareness of PPL and lactation policies remains limited and is not routinely incorporated into professional training, including family medicine residency which impacts policy uptake.

Methods: We developed a 12-question survey exploring themes such as awareness of institutional policies, access to resources, barriers to utilization, and perceived confidence in navigating available supports. Sixteen residents (67%) responded out of the twenty-four who received the survey.

Originality: The policies at our institution provide allowances for PPL and lactation support that meet or exceed national averages. As part of it aims to facilitate a supportive training environment for parent-residents and better understand gaps affecting resident well-being, this group sought to investigate persistent barriers to PPL and lactation resource utilization despite the presence of robust institutional policies.

Lessons learned and future implications: Half the respondents (50%) reported that they felt very familiar with the institution's PPL policy. Nonetheless, the survey revealed a lack of information and resources as the most frequently reported barrier faced when requesting PPL, while the most reported barrier to breastfeeding was scheduling conflicts.

Discussion: Graduate medical education often overlaps with childbearing years. Formal leave and lactation policies when they exist, facilitate smooth transition for residents between their roles as parent and trainee, and support re-integration into clinical duties. However, even when documented, knowledge of and access to these policies are often lacking. In addition, perceptions reinforced by the hidden curriculum in medicine, along with logistical constraints pose barriers to breastfeeding and by extension parent and child wellbeing.

Conclusion: Our findings indicate that highlighting available lactation and PPL policies, for instance through formal curricula, orientation sessions, or discussion panels, can increase understanding and utilization of current parental leave and lactation support resources during medical training. Additionally, innovative solutions to scheduling-related barriers are needed to better support lactating parents during family medicine residency.

ID 825- Experiences of Patients Using Complementary and Alternative Medicine in Primary Care

Rahma SAKKA [(1)] , Yassine MAALEJ [(2)], Amira OUIRIEMMI [(2)]

(1) Family Medecin Trainee, Sfax, Tunisie
(2) General Surgery Consultant, Tataouine, Tunisie

Context: The digestive system injuries during a blunt abdominal trauma represent1-5% of the small intestine injuries. The sigmoid colon is an uncommon site, accounting for less than 1%. We present a case of a 65-year-old male presenting an isolated sigmoid perforation from a 3-meter fall.

Methods: A 65-year-old male, with no medical history, presents with generalized abdominal pain following a 3-meter fall. The CT scan confirms the diagnosis of an isolated sigmoid colon perforation with a large pneumoperitoneum, most likely due to trauma-induced perforation of a pre-existing sigmoid diverticulum. Initially, we admit the patient to the surgical department for preparation before an Emergency exploratory laparotomy through a midline incision involved sigmoid colon resection and the performance of a double-barrel colostomy using the Wolkmann technique.

Originality: First of all, this case reports on the least common sites of perforation. Second, the mechanism resulting from a vertical force with direct abdominal impact is less common than the deceleration mechanism. Furthermore, this case demonstrates the critical role of CT scanning with a high-energy mechanism.

Lessons learned and future implications: Firstly, A severe mechanism mandates an aggressive diagnostic strategy, even with poor clinical signs and a normal FAST exam. Secondly, the elderly patients can display minimal signs of peritonitis while hiding severe intra-abdominal injuries. This case reinforces the need for clinical protocols that automatically trigger CT imaging in elderly patients regardless of a benign clinical appearance.

Discussion: The rarity of sigmoid injury is well-documented, with most series showing it constitutes a small minority of colonic traumas [Cite: Watts et al.]. The diagnostic challenge we faced is classic; as described by Fakhry et al., delayed diagnosis means poor outcomes. Our case demonstrates a successful pathway to avoiding such a delay: the severity of the mechanism justifies advanced imaging immediately. The CT finding of pneumoperitoneum confirms the diagnosis. Brasel et al. established that free intraperitoneal air or fluid without solid organ injury is highly suspicious for perforation.

Conclusion: Isolated sigmoid colon perforation from blunt abdominal trauma is a rare but lethal injury that demands vigilance, driven by the mechanism of injury, and promptly investigated with CT imaging, to ensure timely surgical intervention and optimize patient outcomes.

ID 61- Exploring Barriers and Enablers of Hypertension Screening Practice Among Middle-Aged Adults in Ethiopia: A Qualitative Study

Carolina MADUREIRA, Ana Catarina MAIA

Uls Coimbra, Coimbra, Portugal

Context: In 2024, a group of Family Medicine residents created a non-profit association to promote medical education and strengthen community engagement. This initiative aimed to improve the scientific quality of an annual congress organized by the group and to establish partnerships with recognized institutions, amplifying its educational impact.

Methods: The process involved several sequential steps: legal registration of the association, opening a bank account, and declaring the start of activity. Each stage posed considerable bureaucratic challenges for a team without prior administrative or financial expertise. Completing legal documentation required understanding complex regulations, while opening a bank account involved comparing institutional conditions. Declaring the start of activity proved particularly demanding due to limited financial literacy in

medical training. These obstacles were overcome through systematic research and direct communication with official entities. Strengths included teamwork and persistence; limitations involved time constraints and insufficient prior knowledge. A measurable outcome was the successful organization of a congress with improved scientific rigor and broader institutional support.

Originality: Although professional associations are not uncommon, few reports describe the practical steps and challenges encountered by early-career physicians in establishing such structures. This case is distinctive in emphasizing the bureaucratic and organizational learning process, an aspect rarely addressed in the literature on medical education initiatives.

Lessons learned and future implications: Key lessons include the critical role of coordinated teamwork combined with early, proactive engagement with regulatory authorities. Future initiatives should integrate administrative and financial training into residency programs to prepare physicians for leadership and organizational roles. While this experience underscores the need for caution regarding legal and financial planning, it demonstrates that such efforts can substantially enhance educational outcomes.

Discussion: The creation of the association strengthened peer communication, fostered collective learning, and enabled strategic partnerships with scientific institutions, culminating in a higher-quality congress. It also highlighted a gap in non-clinical skills within medical education.

Conclusion: Establishing non-profit associations among healthcare professionals is essential for promoting health literacy, organizing scientific events, and supporting professional development. This practice-based reflection illustrates the value of teamwork and offers a replicable model for other groups seeking to advance medical education and community engagement.

Context: The Learning Health System (LHS) is a transformative model for continuously enhancing quality of care, through ongoing audit and feedback loops using advanced technologies, data integration, stakeholder participation, and alignment with the Quintuple Aim framework. Despite its proven potential, its implementation remains limited in Europe and Canada. Given advancements in information technology, increasing pressures on healthcare systems and growing burden of chronic diseases, there is an urgent need to scale up LHS in primary care.

Objectives: By the end of this workshop, participants will be able to: Discuss barriers and facilitators to the large-scale LHS implementation within interprofessional primary care teams (PCT) Foster strong partnerships with patients and all stakeholders to ensure meaningful engagement Identify how scalability assessment plays a role in achieving greater equity and humanism in primary healthcare within the scaling process using ISSaQ 4.0 to evaluate the scalability of a large-scale LHS across multiple jurisdictions.

Teaching method and workshop: Interactive strategies, including expectation mapping, small-group discussions, table-based reflections, and plenary exchanges: Participants will engage in practical exercises and collaborative analysis to reinforce learning. Workshop schedule (60 minutes

Expected outcomes: At the end of this workshop, participants will understand barriers and facilitators to the large-scale LHS

implementation within interprofessional PCT and gain insight into how scalability assessment plays a role in achieving greater equity and humanism i

Conclusion: The LHS has potential to be a transformative model for continuously enhancing quality of care and foster meaningful partnerships and patient engagement. This workshop will act as a lever for future collaboration across multiple and international jurisdictions.

Jihyun YOON [(1)], Seungmin NAM [(2)]

(1) Korea University Anam Hospital, Seoul, Corée (République de)
(2) Kyoto University, Kyoto, Japon

Context: Shared Decision Making (SDM) is essential for patient-centered care. While global adoption is increasing, implementation in Korean primary care remains limited.

Objectives: To review global SDM policies and analyze the feasibility of their application in Korea, focusing on the role of family medicine specialists.

Methods: We conducted a narrative review of academic literature and policy documents regarding SDM implementation in the US, UK, Germany, and Canada. We analyzed key success factors from these countries and evaluated their applicability to the Korean context, specifically examining legal frameworks (e.g., Medical Service Act) and the primary care environment.

Results: The review identified that successful SDM implementation requires institutional support. In Korea, barriers include the lack of reimbursement and standardized tools. Based on the comparative analysis, we derived three strategies: 1) Developing Korean-specific models (e.g., adapted Three Talk Model) and Patient Decision Aids (PDAs). 2) Policy reform to introduce an "SDM Counseling Fee" within the National Health Insurance. 3) Mandating SDM training in family medicine residency programs.

Discussion: Current literature suggests that individual physician effort is insufficient for SDM sustainability. Family medicine specialists are ideal leaders for SDM, but structural changes identified in international cases—specifically reimbursement and education—are prerequisites for success in Korea.

Conclusion: Implementing SDM in Korea is feasible if supported by a multi-faceted approach involving tool development, policy reform, and education, aligning with global trends in patient-centered care.

ID 1970- Exploring the Influence of Depression and Anxiety on Adherence to Routine Cervical Cancer Screening: A Retrospective Cohort Study

Tali SAHAR

Dep Of Family Medicine' Hebrew University, Jerusalem, Israël

Context: Uncertainty is inherent to primary care, arising from undifferentiated symptoms, multimorbidity, time pressure and limited investigations. When unaddressed, it can lead to over-testing, defensive practice, clinician burnout and patient anxiety. Yet explicit training in how to recognise, tolerate and communicate clinical uncertainty is still limited in many family medicine settings. This interactive workshop aims to provide practical tools for navigating diagnostic and prognostic uncertainty in everyday consultations.

Objectives: Identify common sources and patterns of clinical uncertainty in primary care consultations. Use concrete communication strategies that acknowledge uncertainty while maintaining trust and partnership. Apply structured safety-netting and shared decision-making in situations of residual uncertainty (e.g. persistent pain, non-specific symptoms, multimorbidity). Reflect on their own emotional responses to uncertainty and how these responses influence clinical decisions.

Teaching method and workshop: This 60-minute workshop combines brief evidence-informed presentations with highly interactive learning. Using real-world primary care vignettes, participants will work in small groups to map types of uncertainty (diagnostic, prognostic, therapeutic) and

Expected outcomes: Participants will leave with a shared language for discussing uncertainty, a set of tested communication phrases, and a simple framework for safety-netting in common primary care scenarios..

Conclusion: Our aims is to supporti Family physicians' confident, transparent and patient-centred care in the face of unavoidable uncertainty

Corresponding author: Tali Sahar, talisahar@gmail.com

ID 507- Exploring the relationship between sleep apnea and mental health disorders based on data from the Korea National Health and Nutrition Examination Survey(2021)

Carolina MADUREIRA, Ana Catarina MAIA

Uls Coimbra, Coimbra, Portugal

Context: Cytolytic vaginosis (CV) is an under-recognized cause of vulvovaginal symptoms, characterized by lactobacillus overgrowth, epithelial cytolysis, and low vaginal pH. Its clinical overlap with vulvovaginal candidiasis (VVC) and bacterial vaginosis (BV) often leads to misdiagnosis and prolonged ineffective antifungal or antibiotic treatments.

Methods: A 28-year-old woman, previously healthy, presented with cyclic vulvovaginal burning, dyspareunia, and increased non-adherent discharge, without pruritus, persisting for over three years. Despite multiple courses of antifungals (long-term fluconazole) and antibiotics for presumed VVC or urinary tract infection, symptoms persisted. Routine gynecological evaluations, cytology, and HPV testing were normal. Discontinuation of combined oral contraception did not improve symptoms, which worsened premenstrually and after alcohol intake. After five years of recurrent complaints and multiple gynecological consultations, the patient presented again for a primary care appointment. A vaginal smear revealed abundant lactobacillus, marked cytolysis, low pH, and absence of fungal or bacterial pathogens, confirming the diagnosis of CV. Treatment with intravaginal sodium bicarbonate irrigations (monthly cycles) achieved complete symptom resolution after three months. A limitation of this case report was the absence of continuous primary care follow-up. Although common etiologies were repeatedly considered, targeted microscopic evaluation was delayed, likely contributing to prolonged morbidity.

Originality: This case illustrates a prolonged diagnostic delay and highlights primary care role in early differentiation, aligning with the literature that underscores lack of diagnostic criteria and frequent misclassification as candidiasis.

Lessons learned and future implications: Early recognition of CV requires systematic inclusion in differential diagnosis for cyclic vulvovaginal symptoms without pruritus. Primary care protocols should incorporate microscopy examination, pH testing, and structured follow-up. Further research should standardize diagnostic criteria and define optimal alkalinization regimens.

Discussion: CV can be reliably distinguished from VVC and BV by microscopy and this case report emphasizes CV’s cyclical pattern, poor response to antifungals and good response to alkalinizing therapy. In patients with persistent vaginal symptoms despite treatment for other suspected causes, cytolytic vaginosis should be always considered, as it can lead to psychological distress and significantly affect self-esteem and sexual wellbeing.

Conclusion: CV is a clinically significant yet under-recognized condition. Timely diagnosis and targeted alkalinizing therapy are crucial to avoid unnecessary interventions and to enhance patient quality of life.

ID 611- Exploring Universal Healthcare and Economics: A Cross-Country Comparative Study with Correlations of Economic Parameters with UHC SCI Scores amongst Southeast Asian Countries

Maria Victoria BAUTISTA PÉREZ [(1)] , Maria Cristina PEDRARES FERNANEZ [(2)], Ines LAGO PEREIRA [(1)]

(1) Resident, A Coruña
(2) Family Doctor, A Coruña

Context: As a young resident doctor, we must give suport on call for emergencies at the hospital. In Spain family doctors are also emergency doctors as well. So imagine being at your first on call and having this request from an old male patient with his lovely wife: We just wanted to check if the cold was progressing properly Doctor.

Methods: We reviewed the case, not important precedents. As he started with a cold a few days before and needed antibiotics with the suspect of progression to pneumonia, we completed the study asking for analitics and chest X- ray. We kept him under observation while working for other emergencies. The surprising results came houres after.

Originality: Sadly, the big point of this case is that the patient passed away because debuting with an acute myeloid leukemia.

Lessons learned and future implications: We work for long hours seeing patients in emergencies that don't actually pose a life-threatening risk, and due to the heavy workload, we might miss certain information or requests for procedures. Perhaps in another situation, we would have recommended relative rest and follow-up with primary care for patients with cold-like symptoms. Is every suspicion of pneumonia, therefore, worthy of exhaustive testing? Probably not. But the importance of reporting these cases, in my opinion, lies in keeping us always vigilant when dealing with at-risk patients.

Discussion: In spain this disease affects between 3-5 of 10.000 patients, and only 48% of them survives one year after the diagnosis. The earlier the diagnosis is made, the greater the survival rate.

Conclusion: Primary care and emergency doctos can achieve early diagnoses of very deadly diseases. Simply by deepening active listening to the patient and taking a good medical history. Sometimes we dont have to wait for patients to ask how the cold must be progressing if we anticipate with a simple cuestion: how are you feeling recently?

Corresponding author: Maria Victoria Bautista Pérez, maria.victoria.bautista.perez@sergas.es

ID 818- Extreme Diet–Related Syncope in a Young Adult: The Diagnostic Value of Comprehensive Nutritional Assessment in Primary Care

Joana ESTORNINHO, Alexandre SANTOS, Inês CAETANO, Mariana SANTOS

Uls Lisboa Ocidental, Lisboa, Portugal

Context: Phytophotodermatitis is a non-immune, inflammatory phototoxic reaction caused by topical absorption of plant-derived photosensitizers, such as furocoumarins, followed by ultraviolet exposure. Diagnosis is essentially clinical, and management is primarily preventive. This case emphasizes the importance of thorough history-taking in Primary Health Care (PHC).

Methods: This case report was based on clinical observation and detailed anamnesis during a PHC consultation. The diagnostic process relied on correlating lesion characteristics with patient history, without complementary tests. Literature review on phytophotodermatitis and its triggers supported interpretation.

Originality: The case demonstrates how a rare but benign condition can mimic more severe disorders, such as coagulation abnormalities, leading to patient anxiety. It highlights the role of the Family Physician in quaternary prevention—avoiding unnecessary investigations and referrals—through clinical reasoning and contextual knowledge.

Lessons learned and future implications: History Matters: Careful anamnesis remains the cornerstone of dermatological diagnosis in PHC. Preventive Counseling: Patients should be informed about risks of plant contact under sunlight, especially citrus fruits. Quaternary

Prevention: Avoiding overdiagnosis and unnecessary tests protects patients and optimizes resources. Future Implications: Educational strategies on phototoxic reactions could reduce misdiagnosis and improve patient safety.

Discussion: A 22-year-old woman, Fitzpatrick phototype III, presented with multiple hyperpigmented lesions on the hands and abdomen, evolving from erythema without vesicles or pain. Concerned about a coagulation disorder, she denied unusual product use. Detailed history revealed recent sun exposure while squeezing limes, explaining the irregular pigmentation pattern. Diagnosis of phytophotodermatitis was established clinically, and topical treatment initiated. The patient was reassured that pigmentation could persist for weeks to months. Citrus fruits, rich in furocoumarins, are frequent triggers. This case illustrates the importance of correlating environmental exposures with dermatological findings to avoid unnecessary investigations.

Conclusion: Phytophotodermatitis, though benign, can cause diagnostic uncertainty. The Family Physician's ability to integrate history and physical examination ensures accurate diagnosis, prevents overmedicalization, and reinforces preventive care. Awareness of phototoxic reactions should be part of routine counseling in PHC.

ID 80- Facteurs Motivants et Barrières au Dépistage du Cancer du Sein : Une Étude au Centre de Soins de Base de Sidi Mansour-Sfax-Tunisie

Maria Victoria BAUTISTA PÉREZ [(1)] , Maria Cristina PEDRARES FERNANEZ [(2)], Marta YAÑEZ MENDIA [(3)], Maria Luisa GARCIA MUIÑOS [(4)]

(1) Resident Doctor (r1), A Coruña, Espagne
(2) Family Doctor, A Coruña, Espagne
(3) Resident Doctor (r4), A Coruña, Espagne
(4) Nurse, A Coruña, Espagne

Context: Family medicine has been recently perceived as a mechanism that regulates access to specialists, despite the vital role in the patient's life. This is especially true when requires pain management or emotional support for patients with therapeutic limitations.

Methods: A 91-year-old man, poorly differentiated squamous cell carcinoma in 2024 , treated with radiotherapy and controlled until its progression. Among other comorbidities, he has Parkinson and cognitive decline. After being examined by maxillofacial surgeons, dermatologists, oncologists... he reached the terminal stage without significant improvement. He did not present other risk factors for imminent death and initial pain was controlled (not even a paliative candidate). This summer, he progressed with nighttime pain and rapidly growth and the biggest challenge we had was supporting the patient depression and the despair of his daughters (also primary caregivers).

Originality: Its important collaborative work with nursery, also pain management and follow primary caregiver. This case raises awareness of the importance of not droping out on terminally ill patients and families. Perhaps this experience differs because of the involvement of the nursing team, as they proposed increasing the number of visits given that, due to their workload, the physician cannot always do. We have learned that terminally ill patients require holistic approaches, focusing on comfort and their emotional well-being.

Lessons learned and future implications: This fosters the social aproach on every patient and how practices based on this knowledge might be helpfull not necessary terminals. As family physicians, we must consider the environment of our patients, especially when dealing with their caregivers. Although society still demands to refer them to specialists, we should sometimes be willing to collaborate with nurses and provide the attentive listening and counseling needed. Last but not least, primary care may be perfectly equipped to manage pain control, even providing palliative care.

Discussion: How gratefull patient and family were, support the practical aproach. Could be limitated as a very singular case of pain management and care give, but also we believe

that the big point is to make doctors aware of this situations.

Conclusion: We reinforced primary care as the basis for monitoring the most vulnerable patients who equally deserve best care

Corresponding author: Maria Victoria Bautista Pérez, maria.victoria.bautista.perez@sergas.es

ID 1500- Factors and determinants of primary care to tertiary care referrals in XXX: A multi-centre analysis using artificial intelligence-powered large language models

Sofia BENTO, Joana SOUSA GOUVEIA, Mónica FONSECA, Inês VENÂNCIO

Unidade De Saúde Familiar Areeiro, Unidade Local De Saúde São José, Lisboa, Portugal

Context: Family medicine serves as the entry point to the healthcare system, where clinicians encounter patients with undifferentiated symptoms. Management requires addressing the medical conditions while considering the patient holistically – familial, occupation, social and cultural circumstances. This ensures care extends beyond the disease to the person, reflecting the core principles of family medicine.

Methods: A 52-year-old male, originally from Brazil and living in XX, with 12 years of education and employed as a long-distance driver, presented with polyuria, polydipsia, leg cramps, and a 20 quilograms weight loss over two months. He was obese (106 kg, BMI 33,5 kg/m2), with no prior medical conditions, medications, or allergies. Family history included a brother with pre-diabetes. Initial evaluation revealed capillary glucose 367 mg/dL and diastolic blood pressures >90 mmHg, heart and lung auscultation were normal. As this was his first visit, blood work, opportunistic colorectal cancer screening, and ambulatory blood pressure monitoring were requested. Follow-up was scheduled in four days. The patient did not have the results at the follow-up visit and missed a rescheduled appointment. He returned one month later with persistent symptoms. Labs revealed HbA1c 15,6%, LDL-cholesterol 164,8 mg/dL, and creatinine 0,93 mg/dL. Considering upcoming travel and lack of immediate safety measures, a shared decision was made to strat intensive oral and injectable antidiabetic therapy with lifestyle counselling. On follow-up, he was asymptomatic, well-adapted to the therapy, and lifestyle modifications were implemented. HbA1c decreased to 6,7% three months after the initial blood work and 5,8% six months after follow-up labs.

Originality: This case illustrates a common diabetes presentation but highlights how non-clinical factors can influence therapy. It emphasizes holistic assessment and shared decision-making in primary care.

Lessons learned and future implications: Acute care visits may involve patients with largely unknown circumstances, warrating caution against premature decisions. Continuous care, timely follow-ups, and evaluation of social, cultural, occupational, and familial factors are essential for safe, personalizes management.

Discussion: This case underscores complex decision-making, flexible protocols, short-term follow-ups, patient engagement, and anticipatory management.

Conclusion: This case reinforces family doctors' ability to integrate medical decisions with patients' life circumstances, improving chronic disease management in primary care.

ID 370- Factors influencing the practice of gynecology in general medicine:quantitative study of general practitioners practicing in the XXXX region

Rim GHALI, Barbara BARBARA, Kelsey HEGARTY

University Of Melbourne, Parkville, Australie

Context: Media reports propose a time when artificial intelligence (AI) programs will supplement or replace doctors. Whilst this may seem outrageous, programs with AI capacities are already embedded in the clinical workflow of a digitally enabled practice. For example, warnings when contraindicated medications are prescribed utilises simple if-then logic and

natural language processing (NLP) software. Similarly, clinical decision support programs can prompt doctors to consider ordering a test following diagnosis to improve care. These programs could potentially reduce the family doctor's cognitive burden and improve patient diagnosis or early intervention. We aim to review NLP models in primary care since 2020.

Methods: A research protocol for this review has been developed a priori. MESH and free-text search terms were developed for the following 3 concepts – NLP models, general practice, risk prediction or classification. A literature search conducted on 5 databases (Pubmed, Medline Ovid, Scopus, Web of Science, CINAHL) was conducted in July 2025. 695 non-duplicate articles were identified and uploaded to an online literature management software (Covidence). Titles and abstracts were screened according to pre-defined inclusion criteria by two authors. Discrepant findings were independently adjudicated by a 3rd reviewer. Following screening, exclusions were made based on the pre-determined criteria. Included papers were reviewed and analysed using Nvivo software.

Originality: There is no up to date published review of current applications of NLP for risk prediction in primary care. This scoping review fills this gap. A review of all AI implementation studies in 2020 reported on 90 studies relating to community based primary health care. Of these, only 3 utilised NLP models for risk prediction.

Lessons learned and future implications: Potential benefits to patients, practitioners and the healthcare system have been reported in a systematic review of AI implementation studies in community based primary health care.

Discussion: Applications utilising NLP that can be used to improve risk prediction from free text clinical notes, potentially enhancing existing clinical decision support systems and future applications in primary care, however their use remains in early stages.

Conclusion: The digital health revolution has long been progressing, however, as wielders of evidence-based practice, we must assess the reality of current applications of NLP models

ID 2125- Falls in an older adult revealing medication-related orthostatic hypotension: A case report

Mariana NEVES, Ana Sofia OLIVEIRA, Isabel GRAÇA, Rita AMARAL

Usf Aníbal Cunha, Uls Santo António, Porto, Portugal

Context: Alcohol consumption remains a major public health concern across Europe. A 2024 WHO-supported analysis of drinking patterns across the EU, Iceland, Norway and Ukraine identified six distinct patterns shaped by beverage preference, prevalence of heavy episodic drinking (HED) and proportions of lifetime abstainers. Across clusters, higher HED rates and increased alcohol per capita consumption are consistently associated with greater harm. These regional differences underline the importance of equipping primary care clinicians to identify varying drinking patterns and respond effectively.

Objectives: Deepen understanding of drinking patterns and their health impacts. Build confidence in using screening tools and risk stratification. Strengthen communication skills, including motivational interviewing and brief interventions. Improve clinical reasoning for managing risky use and dependence. Promote a person-centred, continuity-focused approach to reducing alcohol-related harm.

Teaching method and workshop: The workshop uses an interactive problem-solving approach centred on a clinical decision map exercise. Small groups analyse structured clinical scenarios representing different drinking patterns based on European epidemiological clusters (e.g., high-spiri

Expected outcomes: Participants will gain practical skills to integrate alcohol screening into routine care, tailor interventions to risk level, recognise dependence and support patient-centred behaviour change. Incorporating European epidemiological insights enables clinic

Conclusion: This workshop provides primary care clinicians evidence-based tools for

addressing alcohol use effectively within routine consultations. By combining epidemiological context, structured clinical reasoning and communication strategies, participants will be better prepared to identify risky drinking patterns, intervene early and support sustained change, reinforcing the central role of primary care in reducing alcohol-related harm across Europe.

ID 355- Family Cohesion and Adaptability in patients with uncontrolled and controlled type 2 Diabetes

Catarina MIRANDA-LOURENÇO, Catarina GOMES, Miguel MARQUES FERREIRA

Unidade De Saúde Familiar Tejo, Unidade Local De Saúde De São José, Epe, Lisboa, Portugal. Centro Clínico Académico De Lisboa, Lisboa, Portugal, Lisboa, Portugal

Context: Telemonitoring enables continuous and remote access by healthcare professionals to clinically relevant data, supporting informed decision-making. The implementation of these tools has demonstrated greater benefits compared with conventional care for several highly prevalent chronic diseases in primary healthcare settings, such as hypertension and diabetes. The development of projects that promote closer surveillance, combined with health education, and that foster multidisciplinary collaboration between hospital services, primary care, family physicians, nursing teams, caregivers, and patients, may be decisive for improving access to care and enhancing disease control. Remote monitoring thus emerges as an essential tool for strengthening care pathways, and its integration into primary care remains a path yet to be fully explored.

Objectives: 1. Acquire knowledge about the state of the art of telemedicine tools 2. Identify clinical situations that may benefit from telemedicine implementation. 3. Understand the key steps required to design and implement a telemedicine project in a primary healthcare center.

Teaching method and workshop: 1. Short introductory presentation: Summary of the current scientific evidence on telemonitoring in primary healthcare. 2. Example of an implementation protocol 3. Jigsaw activity: a) A cooperative learning technique in which students become “experts” on

Expected outcomes: · Gain knowledge about telemedicine and better understand their benefits and limitations. · Develop the ability to critically design and implement telemedicine protocols in primary healthcare.

Conclusion: This workshop provides an opportunity to explore the practical application of telemonitoring in primary healthcare units. By promoting knowledge sharing and hands-on discussion, it aims to support the implementation of telemonitoring strategies capable of improving access to care, communication, clinical surveillance.

ID 1675- Family doctor's clinical schedule: evolutionary analysis of the last decade.

Marina FERNANDES, Coralie BUREAU-YNIESTA

Dumg Limoges, Limoges, France

Context: The professional pathway of general practitioners (GPs) develops through internships and employment during medical studies, followed by ambulatory practice. Trajectories – occurring before, during, after medical training – show considerable diversity. No study has fully described these pathways or analyzed links between trajectories and modes of practice in general medicine.

Objectives: This study analyzes the professional pathways and medical practice of GPs in XXX according to temporality (before, during, after studies) and typology (typical, atypical), and explores their influence on clinical practice. It is an ancillary study to a broader analysis of educational pathways and their impact on medical practice.

Methods: We conducted a regional, cross-sectional, descriptive, observational study, using a mixed-methods design (quantitative: Excel®, BiostatTGV®; qualitative: data standardization, typological classification – «

typical »: any employment accessible to medical students or in paramedical fields without specific degrees –, thematic analysis of free-text responses). A self-administered questionnaire, distributed over three months to GPs, explored professional pathways by temporality, current medical practice and perceived influence on practice. Five dimensions were assessed: practice mode, setting, organizational structure, schedule and patient panel.

Results: Participation ranged from 31.01% (1,346 GPs) to 21.87% (949). The primary outcome was statistically significant ($p < 0.05$). Professional pathways, atypical initially, gradually shifted toward medical specialization: 15.53% typical before studies, 56.79% during, 78.09% after. Atypical orientations remained the most frequent model across population characteristics and all five dimensions. Regardless of timing, the health and social, cultural, and sports sector – typically classified – dominated (32.72%), followed by services to individuals and communities (22.77%, mainly atypical), education and training (9.99%, more typical). Most experiences occurred during studies (54.08%). Certain sectors influenced practice mode and patient panel: health, services to individuals, politics/religion had positive effects, while education positively affected practice mode. Politics/religion negatively impacted schedule.

Discussion: No previous study has explored GPs' professional pathways, giving this work originality and relevance. Strengths include a comprehensive questionnaire, high participation, multi-level analysis and statistical power. Limitations include recall bias, a novel typological classification, geographic scope.

Conclusion: This study highlights an enriched model of general practice. Future perspectives include national expansion and creating a directory of French GPs' professional pathways.

Corresponding author: Marina Fernandes, marinafernandes65@gmail.com

ID 1121- Family history and risk of major adverse cardiovascular events in a Korean national screening cohort

Katarina KOVACOVA

Slovak Society Of General Practice, Bratislava, Slovaquie

Context: Background: Herbal preparations, nutraceuticals, and concentrated food extracts are increasingly consumed by patients who perceive them as natural and therefore safe. However, many of these substances significantly influence drug metabolism—most notably through cytochrome P450 and P-glycoprotein inhibition—and may contribute to drug-induced liver injury (DILI). With rising multimorbidity and polypharmacy, interactions between prescribed therapy and food-derived products represent an under-recognised challenge in general practice.

Methods: We describe a 65-year-old patient followed for ulcerative colitis in stable remission. During a routine specialist check-up, progressively rising hepatic and cholestatic markers were identified. Peak laboratory values were markedly abnormal: total bilirubin 39.08 µmol/L (ref. 4.00–22.00), conjugated bilirubin 15.16 µmol/L (ref. 0.00–5.00), AST 2.07 µkat/L (ref. 0.22–0.59), ALT 2.74 µkat/L (ref. 0.15–0.95), GGT 13.88 µkat/L (ref. 0.00–1.13), and ALP 3.25 µkat/L (ref. 0.67–1.99). Abnormalities were confirmed on repeat testing. Liver ultrasound showed no obstructive pathology. A detailed medication and dietary history revealed long-term use of atorvastatin, propafenone, and esomeprazole. Crucially, the patient had recently begun consuming approximately 0.5 L per day of a highly concentrated pomegranate extract. Pomegranate compounds are known inhibitors of CYP3A4 and P-glycoprotein, providing a plausible mechanism of cumulative hepatotoxicity in the context of chronic pharmacotherapy. The clinical picture and temporal association were consistent with an acute mixed hepatocellular–cholestatic DILI. Discontinuation of the extract and adjustment of therapy led to gradual biochemical improvement.This case links a clearly documented DILI episode to a common scenario in general practice: a polymorbid older patient on long-term cardiometabolic medication who adds a "natural" concentrated food product.

Originality: This work offers a concise overview of clinically relevant food–drug interactions with emphasis on hepatotoxic and CYP-mediated mechanisms. Instead of exhaustive pharmacology, it highlights combinations most relevant for general practitioners, including statins, antiarrhythmics, warfarin, immunosuppressants, and herbal or nutraceutical products

Lessons learned and future implications: Complex metabolic concepts (CYP3A4, P-gp, vitamin K, potassium balance, tyramine) are translated into practical red-flag examples applicable in routine counselling and medication review.

Discussion: This case underscores the underestimated risk of interactions between commonly prescribed medications and concentrated food extracts.

Conclusion: Routine inquiry about supplements and nutraceuticals should be a standard part of primary care assessment, particularly in polymorbid patients on long-term therapy.

ID 1843- Family medicine capacity and ambulance demand: a 13-year equity analysis using linked administrative data

Daniela CORREIA, Pedro LOPES

Uls Estuário Do Tejo, Lisboa, Portugal

Context: Over the past few decades, overweight and obesity have been rising, with no signs of slowing down. In spite of being an important risk factor for the development of non-communicable diseases, these conditions can cause additional complications in pregnant women and, consequently, in their children.

Objectives: The aim of this review was to evaluate the prevalence of maternal obesity and overweight in the area of Aveiro region.

Methods: An observational, cross-sectional study was conducted. The population studied included pregnant women with one fetus, monitored in primary health care units', with weight and height records and who had not voluntarily terminated their pregnancy.

Results: Among the 2020 participants, the prevalence of overweight/obesity was 41.9%. Pre-gestational overweight and obesity were identified as significant predictors of pregnancy complications, particularly gestational diabetes, neonatal macrosomia, and increased likelihood of cesarean delivery.

Discussion: Maternal overweight and obesity remain highly prevalent and significantly impact pregnancy outcomes, increasing maternal–fetal morbidity. Our findings reinforce global trends and highlight the urgent need for preventive strategies in primary care. Early identification, nutritional counseling, and weight-management interventions are essential to reduce risks and improve long-term health for mothers and children.

Conclusion: Pre-gestational overweight and obesity are associated with increased maternal-fetal morbidity, but these conditions are preventable and treatable. It is imperative the development of strategies to detain this recognized Public Health problem.

ID 1403- Family medicine clinic: How to manage ‘a day in the life’ (An interactive experience)

Cecile VO NGOC, Valentine LEFRANC

Aix-Marseille Université, Marseille, France

Context: Indoor air pollution is a major issue in environmental health. General practitioners spend at least one third of their time in consultation rooms, where they may be exposed to indoor air pollutants whose levels remain poorly documented.

Objectives: To assess indoor air quality of general practice consultation rooms and to identify factors that may influence it.

Methods: A descriptive quantitative observational study was conducted between February and September 2023, as part of the XXX project funded by XXX. Sensors installed in consultation rooms continuously measured

CO_2, PM2.5, and formaldehyde. For each room, ICONE confinement indices were calculated based on CO_2 levels. Indicators of central tendency and dispersion were also computed for each pollutant. Simultaneously, ventilation practices were collected through an anonymous questionnaire completed by participating physicians. A comparative analysis was performed to explore potential associations between these practices and ICONE indices.

Results: Ten sensors collected data across thirty-five consultation rooms. Forty percent of them showed at least "high" confinement (ICONE ≥ 3), and 60% of CO_2 measurements exceeded 800 ppm, which is a key value for ventilation management. Despite these high confinement levels, most formaldehyde and PM2.5 concentrations remained below established health-based thresholds. Ventilation practices varied widely among physicians, but no statistically significant association was identified between these practices and confinement levels.

Discussion: High ICONE values suggest substantial exposure to chemical and biological pollutants. However, measured concentrations of formaldehyde and PM2.5 were lower than those reported in studies led in homes or schools. The absence of an association between confinement and ventilation practices may reflect specific characteristics of general practice indoor environments or a lack of statistical power due to the small sample size. A larger and year-round study would be valuable to strengthen and refine these findings.

Conclusion: General practice consultation rooms exhibit high confinement level. Promoting improved ventilation practices appears relevant to reduce exposure to indoor pollutants and limiting contamination risks within these healthcare settings.

ID 1539- Family Medicine in Precision Public Health: Building the Foundation of Better Care

Khrystyna FEDAK, Adriana MARQUES FERREIRA, Hugo SEVIVAS SERRALHEIRO, Mariana REIS, Carla Marina GONÇALVES

Ruães Family Health Unit, Braga, Portugal

Context: Infections caused by mycobacteria, including both the Mycobacterium tuberculosis complex and non-tuberculous mycobacteria, represent a significant cause of morbidity in immunocompromised patients. Deficient cellular immunity predisposes to atypical and diagnostically challenging presentations. This report highlights two such cases, emphasizing the need for careful clinical evaluation and a multidisciplinary approach.

Methods: Case 1: A 28-year-old woman, self-employed, immunocompromised due to anti-TNF therapy for Crohn's disease, presented to the Family Health Unit with a painful ulcerative vulvar lesion. She was referred to the emergency department, where a biopsy was performed, revealing epithelioid granulomas and confirming Mycobacterium tuberculosis infection. Case 2: A 27-year-old man, self-employed, on antiretroviral therapy for HIV infection and co-infected with HCV, under follow-up in the hospital's Infectious Diseases department, presented to the Family Health Unit with four days of rectal bleeding and was initially treated for probable hemorrhoidal disease. One month later, he returned due to persistent post-defecation rectal bleeding, associated with diarrhea—approximately 10 loose stools per day—and intermittent low-grade fever. On physical examination, an elongated erythematous protrusion was observed on the anal mucosa. He was referred to the emergency department, where stool cultures for mycobacteria identified Mycobacterium intracellulare.

Originality: These cases illustrate rare presentations of mycobacterial infections in immunocompromised patients. Case 1 involved a vulvar M. tuberculosis lesion in a woman on anti-TNF therapy, while case 2 featured gastrointestinal M. intracellulare in an HIV/HCV coinfected patient, initially mimicking hemorrhoidal disease. Although such infections are documented, their atypical manifestations highlight unique diagnostic challenges.

Lessons learned and future implications: These cases highlight the need for high clinical suspicion of opportunistic infections in immunocompromised patients, even when symptoms appear common. Early diagnosis requires thorough evaluation and targeted laboratory testing. Future practice should emphasize routine screening in high-risk populations and multidisciplinary collaboration to minimize diagnostic delays.

Discussion: These cases highlight the challenges of diagnosing opportunistic infections in immunocompromised patients. Accurate diagnosis requires careful consideration beyond common clinical assumptions and relies on combining clinical evaluation with laboratory and histopathological findings.

Conclusion: These cases emphasize the value of updated protocols, multidisciplinary care, and professional training to enable early detection, optimize patient outcomes, and support public health planning.

Context: Selfcare is an important element of GP's health care, aimed - among other things, at preventing burnout. Unfortunately, it's often omitted, both during medical studies and postgraduate training. This workshop addresses this issue by exploring possible strategies, with the goal of equipping family physicians with tools to make this difficult task easier.

Objectives: Identifying selfcare needs and resources for healthcare professionals. Designing strategies for effective implementation into daily practice.

Teaching method and workshop: The workshop will consist of three parts: a conceptual introduction, an interactive presentation of various self-care strategies, and a brainstorming session for networking and creating your own contexts. The unique perspectives of the six presenters will

Expected outcomes: Drawing attention to the importance of working life balance in the daily practice of family doctors.

Conclusion: In an increasingly overwhelming reality, searching for selfcare strategies seems like another challenge to overcome, while at the same time allowing for a healthy distance from the stress of everyday life. Keywords: selfcare, burnout, wellbeing, brainstorming, active learning, lifestyle changes, physical activity, sleep, nutrition, stress, strategies, relationships, contact with nature and animals, emotions, sense of coherence.

ID 21- Family Physicians' Perspectives on Artificial Intelligence in Kosovo's Primary Healthcare: Opportunities, Challenges, and Ethical Reflections

Eunice DE VERA

Dr. Paulino J. Garcia Memorial Research And Medical Center, Sto Domingo, Philippines

Context: Being at the vanguard of primary care and taking a holistic approach to medicine put family physicians in a unique position to diagnose, manage and collaborate with other specialties to provide care for patients with rare diseases.

Methods: This is the case of MR, a 51 year old female from the Philippines who presented with a chief complaint of dizziness. Examination revealed distinct heart sounds on the right side of her chest, raising suspicion for Dextrocardia,

which was confirmed by chest xray. Plain abdominal X-ray and an abdominal ultrasound revealed situs inversus totalis. CBC, peripheral blood smear, serum ferritin and hemoglobin electrophoresis showed alpha thalassemia trait. The patient had no prior history of medical consultations, hospital admissions, or surgeries and had delivered her children through non-institutional means, which likely contributed to the late diagnosis of her congenital conditions.

Originality: Alpha-thalassemia is caused by the reduced or absent production of the alpha globin chains. Dextrocardia is characterized by the heart being located on the right side of the chest. In situs inversus, the organs are arranged in a mirror image. When dextrocardia occurs with situs inversus, it is called situs inversus totalis (SIT), a rare condition affecting about 1 in 20,000 individuals. There has been no reported case of situs inversus totalis associated with alpha thalassemia (Chen, 2020).

Lessons learned and future implications: This case report aims to describe the incidental finding of situs inversus totalis in a patient presenting with dizziness and consulted at a medical facility for the first time. The patient did not have pertinent medical history which contributed to the late diagnosis of her rare conditions.

Discussion: A study by Chen, et. al in 2020 described the comorbidities diagnosed with SIT where the most common comorbidity noted was congenital heart disease. Rodrigues et al. in 2020 described a case report where a newborn was diagnosed with SIT and Sickle Cell Anemia. There were no recorded incidence of SIT associated with Alpha Thalassemia.

Conclusion: It is important that doctors encourage routine medical examination for their patients. A holistic approach is beneficial especially in primary care where primary care physicians are the first point of contact of patients.

ID 1422- Family-Centred Approaches to Familial Dyslipidaemia in General Practice: A Narrative Literature Review

Marina FERNANDES, Coralie BUREAU-YNIESTA

Dumg Limoges, Limoges, France

Context: The traditional pathway leading to general practice extends from secondary school graduation to the specialized medical degree. Although the standard route remains most common, reforms have led to increasingly diverse trajectories. To date, no study has described these pathways or examined their influence on medical practice.

Objectives: This study analyze the educational pathways and medical practice of general practitioners (GPs) in XXX – according to temporality (before, during and after medical studies) and typology (typical versus atypical) – and explore their influence on clinical practice. This work is an ancillary study to a broader analysis of professional pathways and their impact on medical practice according to temporality and typology.

Methods: We conducted a regional, cross-sectional, descriptive and observational study, using a mixed-methods design (quantitative: Excel®, BiostatTGV® ; qualitative analysis: data standardization, typological classification – « typical » : degrees directly related to medical – , and thematic analysis of free-text comments). A self-administered questionnaire, distributed over three months to GPs, explored educational pathways by temporality, medical practice and perceived influence of these trajectories. Five dimensions of practice were assessed: practice mode, setting, organizational structure, schedule organization and patient panel organization.

Results: Participation ranged from 31.01% (1,346 GPs) to 21.87% (949). The primary outcome was statistically significant ($p < 0.05$). Initially typical educational pathways became more diverse over time: 9.28% atypical before, 22.22% during and 26.25% after. The typical pathway remained predominant across population characteristics and all dimensions of medical practice. Secondary-school graduation was most common before medical

studies (43.79%), while university diplomas predominated during (44.83%) and after (54.86%), all classified as typical. Secondary-school graduation and master's degrees positively influenced practice mode. University diplomas and capacity certificates benefited both practice mode and patient panel characteristics.

Discussion: No previous study has investigated GPs educational pathways, making this work original and relevant. Strengths include a comprehensive questionnaire, high participation, multi-level analysis and statistical power. Limitations include potential recall bias, an unprecedented typological classification and geographic restriction.

Conclusion: This study highlights an enriched model of general practice and supports future national extension, development of a directory of pathways and evaluation of the impact of health education reforms on medical practice.

Adriana Lucero JAMES DIAZ, Carolina ECHEGARAY CARRANZA, Cristina HERNANDEZ SANZ, Laura SÁNCHEZ GARCÍA

Cap Vila Olímpica, Barcelona, Espagne

Context: Case of chest pain at primary healthcare centre walk-in clinic.

Methods: 50-year-old male, active smoker, history of hypertension, hypothyroidism. Ramipril 10mg, amlodipine 5mg, eutirox 200 µg. Chest pain which initiated during the night, while at rest. Irradiates to upper abdomen, bilateral neck, left jaw. Improves in right lateral decubitus. Worsens on sitting and on anterior inclination. VAS 8 (0-10). BP 119/60 – 150/100 mmHg SpO2: 95% glycemia 142 mg/dL Unremarkable physical examination. EKG: RS 70 bpm, PR 0.20s, narrow QRS, negative T waves in inferior leads. Emergency referral to hospital: Troponin <14 Creatinine 1.63 mg/dL GFR 48 mL/min CRP 0.26 mg/dL CBC, LFT: normal Chest X-ray: unremarkable Serial troponin: <14 - Paracetamol IV: partial improvement, isolated vomit, anxious patient. Difficulty urinating. Impression: - Mild impairment of kidney function - Atypical chest pain - Possible anxiety component He wishes to be discharged and in light of absence of data suggestive of ACS, he is discharged, instructed to follow-up with his PCP. FOLLOWING DAY: He returns to the healthcentre seeking medical leave. Persistent thoracoabdominal pain with poor food tolerance, profuse cold sweats, fever, and weakness in the lower extremities. Urgent reassessment. EKG repeated, no changes. DD: - Acute gastritis - Pancreatitis - Gastrointestinal perforation Patient referred again to hospital, abdominal CT scan was performed: Stanford Aortic dissection, from the aortic root to the infrarenal descending aorta. The dissection extends to the brachiocephalic trunk, celiac trunk, and superior mesenteric artery. Celiac trunk with dissection extending to a few centimeters distal to the ostium, showing proximal thrombosis within the false lumen. Right renal artery originates from the false lumen. 12h emergency surgery.

Originality: Aortic dissection is not something you see every day. Especially at the primary healthcare level.

Lessons learned and future implications: The importance of considering every piece of medical information is underscored by this case. What could explain the kidney function impairment? How could he have been discharged in the face of the puzzling clinical presentation?

Discussion: More frequently than not, once acute coronary disease is ruled out, chest pain is relegated to the Realm of Anxiety.

Conclusion: Vital that care providers consider potentially fatal diagnoses when confronted with puzzling presentations.

José Guilherme CANDIDO SECCO, Marcos Paulo C. V. HUTCHISON, Márcio Cristiano DE MELO, Naila A. DE OLIVEIRA

São Leopoldo Mandic Medical School, Araras, Brésil

Context: Extension projects integrated into the School Health Program play a key role in addressing mental health concerns among adolescents. This case report describes an innovative intervention using playful educational strategies to detect and manage bullying, harassment, anxiety, and depression among adolescents aged 12–16 within primary care settings. The initiative reinforced the importance of participatory activities as a pathway for early mental-health identification and prevention.

Methods: The project was implemented at a Basic Health Unit (UBS) in São Paulo with the participation of 30 adolescents. The intervention combined playful tools—such as structured games, role-playing scenarios, and guided group discussions—designed to promote expression, emotional literacy, and identification of risk situations. A clinical vignette involving a 14-year-old adolescent with anxiety symptoms and recurrent bullying was used to stimulate reflection and support group-based problem-solving.

Originality: The project uniquely merged playful dynamics with structured health-education strategies, enabling adolescents to engage in sensitive topics in a safe, non-judgmental environment. This integrative approach demonstrated how extension projects can expand the pedagogical and preventive reach of the School Health Program by fostering meaningful dialogue around mental health.

Lessons learned and future implications: The activities effectively facilitated the identification of adolescents experiencing bullying, anxiety, and depressive symptoms. Participants showed improved empathy, communication, and teamwork. The positive outcomes support the scalability of the method. Future project cycles aim to address additional public-health topics, such as dengue without warning signs, using the same playful-educational framework.

Discussion: The intervention demonstrated how university extension projects can strengthen the School Health Program by incorporating creative, adolescent-centered strategies. Playful activities not only promoted engagement but also enhanced the capacity of primary care teams to identify mental-health risks early, integrating clinical vigilance with health education.

Conclusion: This extension project highlights the transformative contribution of playful activities to adolescent mental-health promotion in primary care. The experience reinforces the potential of extension initiatives within the School Health Program to support early identification, prevention, and comprehensive management of mental-health conditions among adolescents.

ID 824- Flying high: modelling drone transport networks for pathology sample collection in

Carolina ECHEGARAY, Cristina HERNANDEZ, Adriana JAMES

Parc Sanitari Pere Virgili, Barcelona

Context: A 70-year-old man with no relevant medical history appear with legs edema coinciding with the onset of warm seasonal temperatures. While initially evaluating for peripheral venous insufficiency, a rapid urine test was performed.

Methods: The urine test showed significant proteinuria, leading to urgent labs that confirmed nephrotic-range proteinuria, hipoalbuminuria, hyperlipidemia and high triglycerides. A kidney biopsy was then performed to determine the underlying renal disease.

Originality: The biopsy confirmed minimal change disease, a rare condition that can take weeks or months to diagnose. This case highlights how a simple, rapid urine test allowed early detection of a pathology not commonly considered in routine evaluations of legs edema.

Lessons learned and future implications: - Rapid urine testing in patients with edema can reveal underlying renal disease even when

initial suspicion points to more common causes, such as venous insufficiency. - Minimal change disease, though rare in adults, should be considered in nephrotic syndrome presentations. - Early recognition allows prompt management, potentially preventing complications from delayed diagnosis.

Discussion: Nephrotic syndrome in adults can appear from various renal diseases, including minimal change disease, FSGS, and membranous nephropathy. Symptoms may imitate common conditions like venous insufficiency. This case shows how simple urine tests can detect proteinuria early, guiding timely biopsy and treatment.

Conclusion: A rapid urine test was key to detecting nephrotic-range proteinuria in a patient presenting with leg edema. This case emphasize the importance of considering renal parenchymal causes in the differential diagnosis of edema and using simple diagnostic tools to uncover potentially serious kidney diseases early.

Usf Do Arco, Lisboa, Portugal

Context: Pneumococcal vaccination is essential for preventing pneumonia and reducing exacerbations in patients with Chronic Obstructive Pulmonary Disease (COPD), a particularly vulnerable group and a priority according to national and international guidelines. At USF do Arco, pneumococcal vaccination coverage was found to be below recommended levels, prompting the development of an intervention project aimed at improving this indicator.

Objectives: The main objective was to increase, over a three-month period, the proportion of COPD patients with up-to-date pneumococcal vaccination to ≥ 85%. Vaccination status was considered up-to-date when patients had received at least one vaccine appropriate to their age and clinical condition, in line with current recommendations.

Methods: The target population was identified using electronic clinical records. The intervention consisted of simple, replicable measures: systematic identification of vaccination status; proactive contact with eligible patients; integration of vaccination checks into all clinical encounters (opportunistic vaccination); development of educational materials, and a brief team meeting to standardize procedures. Evaluation indicators included the proportion of patients with updated vaccination, the number of contacts made, and the acceptance rate of the vaccine.

Results: The intervention is expected to significantly increase pneumococcal vaccination coverage among COPD patients, reducing the risk of pneumonia and exacerbations.

Discussion: By promoting systematic assessment and opportunistic vaccination, this project reinforces a preventive and integrated approach to COPD management within the USF. Its design supports efficiency, feasibility, and alignment with guideline-based care.

Conclusion: The simplicity and sustainability of the intervention allow for continuous incorporation into routine practice and replication in annual quality-improvement cycles.

ID 2226- Fracture Risk in Different Cancer Types in Individuals with Cancer Compared to Adults without Cancer: A Population-based Study from Southeast of Iran

Daniela Florentina STAVARACHI PUIU

Arnau De Vilanova Department, Benimamet Healthcare Centre, Valencia, Espagne

Context: Case report of an unusual cause of severe hypocalcemia

Methods: Data extracted from patient´s elctronic medical records. 64-year-old male patient, smoker, diagnosed with high blood pressure(HBP), rheumatoid arthritis(RA), hiperuricemia, gastroesophageal reflux disease(GERD), on chronic treatment with olmesartan/hydrochlorotiazide 40/12,5mg, lorazepam 1mg, methotrexate 15mg, adalimumab, paracetamole/tramadol 650/75mg and omeprazole 40mg, sometimes prednisone added for acute pain. Followed-up by rheumatologyst for his RA. In a general check-up with the family doctor he complainted of 2,5-month duration paresthesias. One week later he experienced uncounsciousness and seizures, sphincter relaxation and amnesia of the episode. The emergency service referred him to hospital, where the initial blood tests were normal except for very low blood calcium, cerebral CTscan normal. He was admitted to internal medicine department. He responded to intravenous calcium, but still presenting dizziness. Then low blood magnesium was also found and the patient responded well to intravenous Mg treatment. Reviewing his treatment, the initial doubt was addressed to adalimumab, which could be responsible for the severe hypocalcemia, but not for the hypomagnesemia. Eventually, the "winner to blame" was omeprazole, as it can produce low magnesium levels with chronic treatments. The final diagnosis at release was severe hypocalcemia secondary to hypomagnesemia due to chronic use of omeprazole. The patient maintained stability, with no new complaint. Omeprazole and adalimumab were withdrawn and replaced with famotidine, calcium and vitamine D. The patient has a follow up booking within two months.

Originality: I bring this case into discussion because it was difficult to get to the correct diagnosis and because the treatment with omeprazole is very common, although this side effect is very rare, as the bibliographic research showed eventually.

Lessons learned and future implications: Although we oftenly use chronic PPI treatments, we should keep in mind that iatrogenesis could be responsible for severe conditions.

Discussion: Polymedicated patients are at risk of lots of interactions and side-effects of their "drug cocktail", difficult to figure out sometimes.

Conclusion: Even if a patient is on a relatively new treatment line (e.g. biological treatments), their complaints might not be due to it, although it´s our first thought. It´s very important to constantly review chronic treatments, especially when new complaints come across.

ID 1006- Fraternity in the Healthcare Network and Humanity Facing Dyspnea: A Shared Approach to Dyspnea ²α♥

Maria Francisca MOURA DE FREITAS, Maria Clara MARTINS PINTO FERREIRA

Usf Horizonte, Uls Matosinhos, Matosinhos, Portugal

Context: Dermatological conditions are common in general practice and can present diagnostic challenges. Acral fibrokeratoma is a rare, benign, slow-growing tumour, usually hyperkeratotic, affecting extremities such as fingers, toes, or nails. Although uncommon, it should be considered in differential diagnoses of acral lesions. Diagnosis is histological and treatment requires complete excision. (1)

Methods: A 61-year-old previously healthy woman presented to primary care with a painful lesion on the plantar region of her right foot. The pain worsened with weight-bearing, progressively limiting her daily walks. The lesion had been present for approximately 15 years, gradually increasing in size over time, with no history of trauma or other associated dermatological conditions. On physical examination, a pedunculated, skin-colored lesion with a hyperkeratotic tip and broad base was observed on the anterior third of the plantar foot, measuring 15 mm in length and 5 mm in diameter. Complete excision was performed, and histopathological analysis confirmed acral fibrokeratoma.

Originality: Plantar acral fibrokeratoma is rarely described, with most reports involving periungual or digital lesions. This case is notable for its long duration, atypical plantar location, functional impairment, and detection in primary care, followed by timely referral for definitive management.

Lessons learned and future implications: Systematic skin examination is essential. Primary care clinicians should consider rare fibrous tumours in the differential diagnosis of hyperkeratotic acral lesions. Educating patients on skin changes may reduce delays in seeking care.

Discussion: Although uncommon, acral fibrokeratoma has distinctive clinical features that can guide suspicion. Histological confirmation remains essential. Complete excision provides definitive treatment with minimal recurrence.

Conclusion: Recognition of acral fibrokeratoma in primary care enables timely referral, diagnosis, and treatment. Early identification prevents prolonged discomfort and improves patient quality of life. Keywords: acral fibrokeratoma; primary healthcare; dermatology References: 1. Malik S, Erickson CP, Calame A, Cohen PR. Acquired giant plantar fibrokeratoma: case report and review. Dermatol Online J. 2021;27(5):1–5.

ID 2200- Frequency and symptom burden of Rome based IBS patterns among adolescents in primary care

Agata KULKOWSKA

University Of Opole, Opole, Pologne

Context: A 76-year-old female presented with recurrent episodes of paroxysmal atrial fibrillation (AF) , each resulting in emergency department (ED) admissions and successful pharmacological cardioversion to sinus rhythm. Despite multiple hospitalizations between June and September 2023, the patient was discharged without recommendations for further ambulatory diagnostics. She reported daily palpitations, visual disturbances, and weakness. PMH included diabetes, hypertension, CKD, asthma, heart failure. For prompt diagnostic workup coordinated care model was implemented

Methods: Following persistent symptoms, ambulatory Holter ECG was performed, revealing continuous AF with a ventricular rate of approximately 115/min, episodes of atrial flutter with 2:1 conduction, and transient bradycardia with a pause of 3.1 seconds. After a brief bradycardic episode, spontaneous conversion to sinus rhythm occurred, with rare ventricular and supraventricular ectopy. The patient was urgently referred to the cardiology department, where a pacemaker was implanted (lead positioned near the left bundle branch).

Originality: This case highlights the diagnostic and therapeutic challenges in elderly patients with paroxysmal AF and sick sinus syndrome, particularly in the context of multiple comorbidities. It demonstrates the value of coordinated care in expediting access to advanced diagnostics and interventions, which may otherwise be delayed in standard outpatient pathways.

Lessons learned and future implications: The case underscores the importance of comprehensive ambulatory monitoring and coordinated care in patients with recurrent arrhythmias and syncope. Early identification of conduction disturbances and timely intervention can prevent further complications and improve quality of life. The experience advocates for broader implementation of coordinated care models in primary care settings

Discussion: Despite repeated ED visits, the patient's arrhythmia was not fully evaluated until coordinated care facilitated Holter monitoring and specialist referral. The findings led to the diagnosis of sick sinus syndrome and the need for pacemaker implantation. The case illustrates the limitations of episodic care and the benefits of integrated, patient-centered approaches in managing complex cardiac patients.

Conclusion: Coordinated care enabled prompt diagnosis and effective treatment of

paroxysmal AF and sick sinus syndrome in an elderly patient with multiple comorbidities. This approach shortened the diagnostic process and improved clinical outcomes, highlighting the need for integrated care pathways in the management of complex arrhythmia cases.

Margarida PEREIRA [(1)] , Beatriz NOBRE [(2)]

(1) Uls Braga-Usf Braga Norte, Braga, Portugal
(2) Uls Braga-Usf Sete Fontes, Braga, Portugal

Context: Cat Scratch Disease (CSD), caused by Bartonella henselae, is a frequent cause of localized lymphadenopathy in young adults after exposure to cats—especially kittens. Although typically self-limiting, its presentation can mimic other infectious and inflammatory conditions, making clinical recognition important in Primary Care.

Methods: A 25-year-old woman presented to a Primary Care acute consultation with a two-day history of painful lymphadenopathies. She also reported low-grade fever (maximum 37.9°C), fatigue, headaches, and myalgias. Past medical history included asthma and polycystic ovary syndrome. Current medications were drospirenone/ethinylestradiol and inhaled budesonide/formoterol. No drug allergies were reported. When asked about animal exposure, she revealed that she had adopted a kitten from an animal shelter one week earlier. Examination revealed multiple cat scratches on the hands, arms, and neck, and a pustule with erythema and edema in the left retroauricular area. Tender cervical, supraclavicular, and axillary lymphadenopathies were palpated, more prominent on the left. No systemic warning signs or hepatomegaly were identified. The clinical presentation was consistent with Cat Scratch Disease, and treated with azithromycin (500 mg on day 1, then 250 mg/day for four days), along with paracetamol as needed. At two-week follow-up, the patient showed complete resolution of symptoms.

Originality: This case illustrates efficient history-based diagnosis in Primary Care, avoiding unnecessary investigations. The presence of a well-defined inoculation lesion, not always reported, strengthened diagnostic certainty.

Lessons learned and future implications: Routine questioning about animal exposure is essential when evaluating lymphadenopathy. Early recognition of CSD can reduce diagnostic delays and unnecessary referrals. Decision tools may further support Primary Care assessment.

Discussion: The constellation of unilateral painful lymphadenopathy, inoculation lesion, and recent kitten exposure strongly supported CSD. Evidence indicates azithromycin accelerates lymph node regression in symptomatic cases. The rapid response in this patient reinforces its usefulness in clinical practice.

Conclusion: This case demonstrates how a focused clinical history and recognition of typical findings can lead to timely diagnosis and effective treatment of Cat Scratch Disease in Primary Care, preventing unnecessary tests and ensuring rapid patient recovery.

Context: Toxicological emergencies require rapid reasoning, familiarity with toxidromes and antidotes, and the ability to make decisions under pressure. Traditional lectures often fail to capture the dynamic nature of these situations. Toxin Code adapts the original escape-room concept into an individual, digital, one-hour workshop designed to strengthen clinical decision-making through gamification. Instead of physical materials, participants solve digital challenges that mimic real toxicology scenarios in an accessible and engaging format.

Objectives: -To improve participants' ability to recognize common and severe toxic agents based on clinical presentations. -To reinforce knowledge of key antidotes and indications for their use. -To provide a structured approach to assessing suspected poisonings. -To promote rapid decision-making and critical thinking in simulated emergencies.

Teaching method and workshop: The workshop uses digital puzzles, progressive case disclosure, and guided reasoning tools. 0–5 min – Introduction: Brief presentation of a fictional poisoning scenario and explanation of the interactive format. 5–20 min – Phase 1. Toxic Word Search: Part

Expected outcomes: Participants will gain improved recognition of toxidromes, greater confidence selecting appropriate antidotes, and a practical diagnostic framework applicable to real-life clinical encounters. They will also develop faster analytical skills under time con

Conclusion: Toxin Code demonstrates how gamification can enhance the teaching of toxicology by transforming complex clinical reasoning into an immersive, efficient, and memorable learning experience.

Context: The application of Artificial Intelligence (AI) in telemedicine has the potential to significantly improve healthcare access and quality in rural areas, where resources and medical personnel are often limited. Despite advancements, there remains a need for systematic reviews to assess the efficacy and challenges of these technologies in such settings.

Objectives: This evidence-based review aims to evaluate the current state of AI integration in rural telemedicine, focusing on its effectiveness in improving patient outcomes and accessibility while identifying barriers to implementation.

Methods: A comprehensive literature search was conducted across databases including PubMed, Scopus, and Google Scholar, using keywords such as "AI," "telemedicine," "rural healthcare," and "evidence-based review." Inclusion criteria encompassed studies published from 2015 to 2023 that focused on AI applications in rural telemedicine. Exclusion criteria eliminated studies not available in English, review articles, and that did not report empirical data. The analysis involved qualitative synthesis of the selected studies, with attention to both quantitative findings and thematic insights.

Results: The review identified 25 relevant studies, of which 18 demonstrated significant improvements in diagnostic accuracy and patient satisfaction through AI-enhanced telemedicine platforms. Specifically, AI applications led to a 25% reduction in misdiagnosis rates and a 30% increase in patients' adherence to treatment recommendations. However, barriers such as inadequate internet infrastructure and healthcare provider training were consistently noted, impacting the widespread adoption of these technologies.

Discussion: The findings underscore the dual role of AI as both a facilitator of enhanced healthcare delivery and a challenge due to infrastructural limitations in rural settings. While AI shows promise in improving care, the disparities in technology access must be addressed to realize its full potential.

Conclusion: This review highlights the implications of AI in telemedicine for rural healthcare, advocating for targeted investments in technology infrastructure and training programs. Future research should focus on longitudinal studies to further assess the long-term impacts of AI on health outcomes in these communities, emphasizing collaborative efforts among stakeholders to mitigate barriers.

ID 1640- From dilemma to development: practicing Ethics through peer discussion in family medicine

Isabela Espíndola ESPÍNDOLA, Ana Vitória CASTRO, Maria Gabriela LONGO, Ana Carolina CASALI, Mirella VILELA, Lia JACOB

School Of Medicine, São Leopoldo Mandic, Araras, Brésil

Context: Pre-eclampsia is a major cause of maternal morbidity and mortality, although partly preventable with effective primary care. Low-risk prenatal care enables early risk assessment, recognition of warning signs, and timely preventive measures such as low-dose aspirin and calcium. Understanding the epidemiological profile of affected women helps identify care gaps and guide improvements in primary care.

Objectives: To describe the clinical and epidemiological profile of pregnant women with pre-eclampsia in a tertiary hospital and identify gaps in prevention and risk stratification that should begin in primary care.

Methods: This was a cross-sectional, retrospective, quantitative study based on medical records from a tertiary maternity hospital (XXX), from January 2023 to December 2024. Among 2,764 medical records reviewed, 200 had confirmed pre-eclampsia; of these, 89 were selected using sample size calculation. Sociodemographic variables, obstetric history, comorbidities, medication use, and complications were analyzed. Statistical analyses included descriptive statistics, Spearman correlations, Mann–Whitney U tests, and a classification tree to identify predictors of complications.

Results: The mean age was 31.5 years, and 63% of participants resided in the study area. Hypertensive disorders during pregnancy were prevalent: 78.7% had gestational hypertension and 21.3% chronic hypertension. HELLP syndrome occurred in 6.74% of cases—higher than expected in the general population—and was significantly correlated with imminent eclampsia ($r = 0.320$; $p = 0.002$). The classification tree identified age between 17 and 29 years and marital status as relevant predictors of complications. Previous obstetric events were common but showed no statistical significance.

Discussion: The findings show a profile of young women with metabolic comorbidities and social vulnerability—factors to be identified and managed early in primary care. The association between HELLP syndrome and imminent eclampsia highlights the need for timely recognition of severe warning signs. The higher complication rate among younger women challenges the focus on advanced maternal age, suggesting a key role of social determinants and adherence.

Conclusion: This study highlights the need to strengthen prenatal care in primary care, emphasizing risk stratification, preventive measures, multidisciplinary follow-up, and attention to young, socially vulnerable women to reduce hypertensive complications and maternal morbidity. MeSH: Pre-Eclampsia; Primary Health Care; Prenatal Care; Hypertension, Pregnancy-Induced

ID 663- From Inclusive Education to Impactful Care: Medical Educators as Catalysts for Future Healthcare through DEI Leadership

Agne MESKAUSKIENE, Carl DEANEY, Victoria ELLIS

Marsh Medical Practice, Louth, Royaume-Uni

Context: Rural communities experience disproportionate health burdens driven by structural inequality, limited access to services,

transport barriers, multimorbidity and workforce shortages. The NHS Long Term Plan, WHO frameworks on universal health coverage, and WONCA's vision for equitable, community-oriented primary care all emphasise reducing health inequities through strengthened, multidisciplinary, person-centred systems. In England's rural practices, older populations and high rates of chronic cardiometabolic and respiratory conditions demand proactive, integrated approaches. Qualitative evidence from our rural practice demonstrates that micro-MDT models and condition-specific clinical champions can drive substantial improvements across long-term condition management.

Objectives: To evaluate how micro-MDT models and clinical champions within rural primary care can reduce health inequalities, improve access and deliver high-quality, preventive, patient-centred care aligned with NHS, WHO and WONCA principles.

Methods: A qualitative practice-level review was undertaken of service redesign through the introduction of micro-MDT pathways and clinical champions across pre-diabetes, diabetes, respiratory disease, heart failure, hypertension, CKD, lipid management, learning disabilities and weight-management clinics. Data were drawn from clinical performance indicators, staff feedback, patient outcomes and observed changes in service utilisation. The analysis examined alignment with NHS inequality objectives, WHO equity guidance and WONCA Europe priorities for 2026.

Results: Enhanced upskilling of clinicians, structured micro-MDT pathways and extended holistic appointments enabled earlier diagnosis, evidence-based treatment optimisation and more frequent reviews for multimorbid patients. Performance improved above national benchmarks across lipid optimisation, blood pressure control, heart failure diagnosis, CKD coding and treatment, respiratory prescribing quality and primary cardiovascular prevention. Patients benefited from integrated reviews, clearer goal-setting and improved continuity. The model demonstrated clear contributions to equity goals through improved access, reduced unwarranted variation, and earlier intervention in conditions that disproportionately affect rural and deprived populations.

Discussion: This micro-MDT and clinical champion framework supports key NHS and WHO commitments to equity, early intervention and preventive care, and aligns strongly with WONCA Europe 2026 priorities around tackling inequality, strengthening multidisciplinary primary care, and improving outcomes for underserved populations.

Conclusion: Embedding clinical champions within micro-MDT structures can mitigate rural health inequalities, enhance quality, and deliver scalable, sustainable models of integrated, person-centred care that strengthen equity in primary care systems.

Corresponding author: Agne Meskauskiene, agne.ptr@gmail.com

ID 25- From lungs to legs: a hands-on workshop on POCUS for general practitioners

Beatriz SOUSA NOBRE, Dinis BRITO

7 Fontes, Family Health Unit, Local Health Unit Of Braga, Braga, Portugal, Braga, Portugal

Context: Primary Health Care is essential to sustainable health systems, and Family Medicine is its central provider. Defined by WONCA Europe as both a clinical specialty and an academic discipline, it is guided by universal principles despite national variations. The Wonca Tree illustrates this framework by linking the specialty's six core competencies to twelve key attributes.

Methods: This opinion piece uses WHO and WONCA Europe definitions, along with Family Medicine's six core competencies, to explore how specialization might affect the discipline.

Originality: The article raises a central and increasingly relevant question: Does specialization risk undermining the very essence of Family Medicine? By framing this debate through the lens of core competencies, it highlights a tension not often explicitly addressed—how additional specialization might enhance certain dimensions of care

while potentially weakening the holistic identity of the family doctor.

Lessons learned and future implications: Family Medicine's holistic, wide-ranging approach is its greatest strength, and excessive specialization may undermine this core identity. Still, specialization can provide benefits—such as greater time and expertise for specific conditions—that help overcome follow-up challenges in everyday practice. Moving forward, the field must balance these advantages with the need to preserve its comprehensive, community-focused nature.

Discussion: The six core competencies collectively ensure that care delivered by family doctors remains accessible, equitable, continuous, and deeply connected to both patient and community. Introducing specialization raises important concerns: Could focusing on narrower fields compromise the holistic and integrative approach central to Family Medicine? Might it shift attention away from community needs or undermine the ability to manage undifferentiated problems? Yet, specialization also presents opportunities for improved disease management and patient follow-up. The debate lies in determining how to integrate specialized skills without fragmenting the discipline's core identity.

Conclusion: Family Medicine is defined by its holistic and community-oriented competencies. Specialization offers meaningful benefits but may threaten these foundational principles if not carefully integrated. The challenge moving forward is to find a balance that preserves the essence of Family Medicine while allowing family doctors to expand their expertise in ways that genuinely enhance patient care.

ID 968- From Mechanical Pain to Autoimmune Disease: An Unusual Presentation of Antisynthetase Syndrome

Agne MESKAUSKIENE, Carl DEANEY, Lisa HAITH

Marsh Medical Practice, Louth, Royaume-Uni

Context: This work applies the CAREMELO principles to strengthen digital, person-centred long-term condition care in a rural English practice. Co-design with patients ensured that digital questionnaires, monitoring tools, and educational modules reflected local needs and priorities. Relevance was embedded through tailoring content to common multimorbidity profiles—including diabetes, hypertension, COPD, asthma and cardiovascular disease—while empowering patients to understand symptoms, risks, and treatment goals. Engagement levels were high, including among older adults, with patients reporting greater confidence and ownership of their care.

Objectives: Advancing Digital and Remote Care in Primary Care (CAREMELO: Accessibility, Monitoring, Education). Reducing Health Inequalities and Strengthening Rural Primary Care (CAREMELO: Accessibility, Education, Outcomes). Workforce Sustainability, Innovation and Integration (CAREMELO: Monitoring, Learning, Outcomes).

Methods: Digital tools—home blood-pressure reporting, COPD CAT scores, Asthma Control Test monitoring, bronchiectasis reviews, and remote diabetes education—provided accessible, user-friendly mechanisms for continuous assessment. These tools enabled early identification of deterioration, supporting rapid, targeted follow-up. Digitally delivered education, aligned with CAREMELO's learning-oriented principles, promoted sustained self-management and improved health literacy. The practice has observed near-zero asthma exacerbations since implementation, illustrating improved safety and proactive disease control.

Results: Rural communities face persistent access barriers. CAREMELO informed the development of inclusive digital pathways that prioritised accessibility, including clear language, stepwise instructions, and flexible submission approaches. This reduced reliance on travel and facilitated timely monitoring, particularly for individuals with mobility or transport limitations. By addressing digital literacy through supportive guidance, the model mitigated digital exclusion and

contributed to narrowing rural health inequalities.

Discussion: Embedding CAREMELO within daily workflows improved efficiency, reduced administrative burden, and enabled clinicians to focus on higher-risk individuals. Continuous digital monitoring improved prioritisation, while structured data supported integrated multidisciplinary decision-making. Staff reported improved situational awareness and more meaningful clinical encounters, reflecting WONCA's emphasis on sustainable, innovative, team-based care models.

Conclusion: The integration of CAREMELO principles with digital engagement tools creates a scalable and equitable model for long-term condition management in rural primary care. This approach enhances patient empowerment, improves clinical outcomes, and supports sustainable, person-centred services aligned with WONCA Europe 2026 priorities.

Context: Hepatitis virus infection is one of the most common liver infections in the world. There were about thirteen thousands people died of chronic liver disease or hepatocellular cancer per year in Taiwan annually. Although the clinical impact of chronic hepatitis has been emphasized, health-related quality of life (HRQoL) is getting more and more concerns.

Objectives: The aim of this study was to assess HRQoL in patients with chronic HCV infection by WHOQOL-BREF and EQ-5D, Visual analog scale (VAS) to investigate the difference before and after direct acting antiviral treatment

Methods: This research enrolled 61 adult patients who had HCV hepatitis and receive direct acting antiviral treatment in the hepatic clinic. They were investigated by interview to collect socio demographic data And received WHOQOL-BREF structured questionnaire and EQ-5D & Visual analog scale(VAS) survey before antiviral treatment, and one month after the end of treatment. Informed consent were obtained before starting the face-to-face interview. Clinical characteristics were collect by chart review. The Data was entered into SPSS for Windows Version 17 for analysis and all statistical tests were conducted at the 5% level of significance.

Results: There were 61 HCV hepatitis cases received investigation. 23 males and 38females, their mean age were 54.6±9.3. The mean EQ5D score at baseline is 14.4±0.9, visual scale was 72.9±13.3, WHOQoL self satisfication was 95.7±12.5. ; and mean EQ5D was 13.6±2.8 , visual scale was 81.7±8.9, WHOQoL self satification was 96.8±8.4 at 6 weeks after treatment. By paired- t test analysis, the visual scale of EQ5D showed significant improvement after treatment (P=0.002).

Discussion: .There are studies shown that the impairment in HRQoL for individuals with hepatitis, HRQOL may worsen due to the progression of viral hepatitis and treatment with interferon and Ribavirin. However, this studie was designed to evaluated the HRQoL of HCV patients under direct acting antivirlal tretment, and we found the VAS improvement after 12 weeks treatment.although no obvious improvement by WHOOoL-BREF survey..

Conclusion: Antiviral treatment benefits the HRQoL of patients with chronic hepatitis C.In view of the small sample size , we will further recruit more cases to prove it .

Inês Filipa DOMINGUES TEIXEIRA, João Francisco POÇAS, Inês GOMES CASTRO, João LEMOS, Ana Rita FERREIRA

Usf Cedofeita-Uls Santo António, Porto, Portugal

Context: Familial dyslipidaemia is a significant cause of premature cardiovascular disease but remains frequently underdiagnosed in general practice. The principles of family medicine, including continuity, holistic care, and attention to family systems, create favourable conditions for early recognition of hereditary lipid disorders. Understanding family structures, shared behaviours, and intergenerational patterns enhances risk identification. The genogram, in particular, offers an efficient visual tool to map biological relationships and highlight patterns suggestive of inherited dyslipidaemia.

Objectives: This literature review aimed to explore how familial dyslipidaemia is addressed within general practice consultations and to assess the value of structured family history and genogram-based assessment in improving case recognition, risk stratification, and follow-up. A secondary objective was to identify barriers and facilitators influencing the implementation of family-centred approaches in routine primary care.

Methods: A narrative literature review was conducted using PubMed, Embase, Scopus, and Web of Science. Search terms included “familial dyslipidemia,” “familial hypercholesterolemia,” “primary care,” “family medicine,” “general practice,” and “genogram.” Articles published in English between 2000 and 2024 were screened. Inclusion criteria were studies addressing diagnostic strategies, family assessment tools, or management of familial dyslipidaemia in primary care. Exclusion criteria were studies conducted exclusively in specialist settings or lacking relevance to family-oriented approaches. Thematic synthesis was used to summarise key findings.

Results: Evidence indicates that familial dyslipidaemia remains under-recognised in general practice, with diagnostic gaps often exceeding 70%. Structured family history-taking improves identification of index cases, and genogram use supports recognition of multigenerational patterns consistent with inherited lipid disorders. Family-based counselling increases screening uptake and promotes lifestyle adherence among at-risk relatives. Reported barriers include time limitations, insufficient training in genogram use, inconsistent documentation, and a lack of electronic integration. Facilitators include longitudinal patient relationships and team-based care.

Discussion: The findings suggest that family-centred assessment strengthens preventive cardiovascular care by linking clinical information with hereditary risk patterns. The genogram is useful but remains underused due to practical constraints.

Conclusion: Incorporating systematic family assessment and genogram use can improve the detection and management of familial dyslipidaemia in general practice. Further research should examine the impact of genogram-guided approaches on diagnostic accuracy and long-term cardiovascular outcomes.

ID 667- From Primary Care to Cavitated Empyema: Navigating Diagnostic Complexity in a Frail Older Adult

Carolina ECHEGARAY, Cristina HERNANDEZ, Adriana JAMES

Parc Sanitari Pere Virgili, Barcelona, Espagne

Context: A 48-year-old man came very often to the clinic requesting high-dose benzodiazepines for anxiety and insomnia. He showed clear signs of dependence and initially behaved in a rude, evasive, and verbally aggressive way, making it difficult to assess issues beyond his physical symptoms.

Methods: Despite his rude behavior, I stayed calm and tried to understand his distress beyond his behavior. He eventually revealed a recent cocaine relapse due to financial stress. This allowed me to diagnose depression with substance dependence, and he agreed to recieve psycotherapy, which helped him manage anxiety and stay abstinent.

Originality: What makes this case unique is not the diagnoses, but how the therapeutic relationship changed. A calm and compassionate approach helped the patient feel safe enough to reveal his deeper problems.

Lessons learned and future implications: - Hostile or demanding behavior may reflect profound emotional suffering rather than intentional resistance. - Compassion, beyond basic empathy, can be a powerful clinical tool to facilitate trust and honest communication. - Exploring concerns beyond the patient’s immediate request (e.g., benzodiazepines) is essential for identifying comorbid psychiatric and substance-related disorders. - A strong therapeutic alliance is crucial for treatment adherence in individuals with substance use disorders. - Family medicine, with its continuity and holistic approach, is uniquely positioned to identify and support patients with complex psychosocial needs.

Discussion: Patients with substance dependence often show behaviors that are difficult for clinicians to manage and can trigger defensive or judgmental reactions. This may create a cycle of mistrust and limited

disclosure. In this case a compassionate and non-judgmental approach helped break that cycle and allowed the patient to share essential information.

Conclusion: This case shows that family medicine requires not only clinical expertise but also strong relational skills rooted in compassion. By responding to challenging behavior with understanding instead of judgment. Compassionate care can turn a difficult clinical encounter into an opportunity for meaningful improvement and recovery.

ID 1291- From Pruritus to Persistent Cough: Early clues to an underlying Lymphoproliferative Disorder

Mónica FONSECA, Sofia BENTO, Inês VENÂNCIO

Usf Areeiro-Uls São José, Lisboa, Portugal

Context: Patiens in general practice often present a challenge, especially when their concerns do not align with identifiable biomedical causes. Psychosocial and family-related factors may play an invisible significant role in their behaviour when seeking consultations, This practice-based case explores how structured family assessment tools can uncover hidden determinants of health and reshape the physician's understanding of the patient.

Methods: A recurrent consultee 51-year-old female, attended multiple consultations over several months, frequently expressing anxiety and somatic concerns. A turning point occurred when she expressed distress about her 18-year-old son scheduling his first independent consultation as an adult. To better understand the underlying context of her recurrent attendance, three family assessment tools were applied during consultations: a family genogram, Mitchell's psychogram and the Thrower Circle. These tools facilitated a structured exploration of her personal and family narrative.

Originality: The assessment done was able to uncover significant unresolved trauma: the sudden death of her husband from pulmonary embolism, ongoing identity distress linked to the absence of her biological father, additional family conflict, low self-esteem related to body image and financial insecurity associated with her work. This case demonstrates the value of family assessment tools in understanding recurrent consultations through a biopsychosocial lens.

Lessons learned and future implications: The process highlighted that recurrent attenders may carry complex emotional burdens not immediately visible within standard appointments. Family assessment tools can provide a safe structure for the patients to articulate their losses, relational wounds, and unmet emotional need, elements previously unspoken in clinical encounters.

Discussion: For the physician, these tools can offer insight into the patient's motivations, improve therapeutic alliance, and provide a more person-centered care plan. Implications include the potential benefit of expanding GP training in family assessment, supporting multidisciplinary collaboration, and allocating protected consultation time when appropriate.

Conclusion: This reflection illustrates how structured family assessment tools can reveal hidden determinants behind frequent appointments, enrich relational understanding, and promote holistic, narrative-based care in family medicine. Their thoughtful integration into general practice may enhance diagnostic depth, patient engagement, and therapeutic alliance.

Context: Accessibility needs at conferences remain insufficiently understood and inconsistently met. EYFDM and WONCA Europe are developing accessibility policies, but important gaps exist: limited community awareness, variable implementation, and absence of systematic data. This workshop addresses these gaps by centering voices of individuals with disabilities, neurodivergence, and caregiving responsibilities—perspectives currently underrepresented in policy development.

Objectives: Educate the community on the importance of accessibility considerations; gather experiential data and feedback from diverse participants to inform policy development; amplify voices of individuals with lived experience of disability and neurodivergence; contribute evidence-based insights to ongoing development of accessibility policies.

Teaching method and workshop: Panel discussion&symposium format: speakers from the community representing diverse accessibility needs as well as policy makers. Audience dialogue&open discussion. Structured feedback via survey. Overview of accessibility challenges in medical conference

Expected outcomes: Participants will gain a deeper understanding of accessibility barriers. Generating data to inform evidence-based guidelines. Collected insights to shape the EYFDM/WONCA accessibility policy.

Conclusion: This workshop (symposium) provides a platform for previously underrepresented voices. Data gathered will inform policy improvements, ensuring equitable participation for all.

ID 2144- From screen to clinic: translating longevity protocols to primary care

Fatemeh NAJAFIPOUR [(1)], Sedigheh NAJAFIPOUR [(2)], Simin MOHEBPOUR [(1)]

(1) Shiraz University Of Medical Sciences(sums), Shiraz, Iran (République islamique d')
(2) Jums, Shiraz, Iran (République islamique d')

Context: Background: Family physicians provide equitable, person-centered care, especially in underserved communities. Cultural sensitivity, continuity, and community engagement are essential for effective primary healthcare.

Methods: Experience Description: Over two decades, I cared for diverse populations, including women, children, elderly patients, and those with chronic diseases such as diabetes, hypertension, and mental health conditions. In rural practice, I established trust with residents, managed acute emergencies, coordinated public health initiatives, and collaborated with local councils. Notably, I supervised TB treatment for an HIV-positive young patient, providing medical and emotional support despite social stigma. Later, I continued service in urban family medicine, participated in COVID-19 response through teleconsultation and community education, and mentored medical students and family medicine residents. I also contributed to founding the Iranian Association of Family Physicians and served on its board.

Originality: These cumulative experiences highlight how family physicians navigate medical uncertainty, cultural barriers, limited resources, and emotional distress while maintaining patient dignity

Lessons learned and future implications: Lessons Learned: Cultural sensitivity and community engagement are key to effective care. Continuity of care improves outcomes across ages and conditions. Compassionate care supports vulnerable patients facing stigma or chronic illness. Physician involvement in education strengthens the healthcare system.

Discussion: Implications for Practice: This reflection highlights the essential role of family physicians in delivering holistic, culturally

appropriate care and offers strategies to improve primary healthcare in diverse communities.

Conclusion: Keywords: Family Medicine, Rural Health, Equity, Humanism, Chronic Disease Management, Community Engagement

(1) City St George's University Of London, London, Royaume-Uni
(2) University Of Cambridge, Cambridge, Royaume-Uni
(3) Keele University, Keele, Royaume-Uni

Context: Identification of 'at risk' individuals is a core part of primary care practice. Screening programmes are complex and resource-intensive interventions, which must be carefully designed and delivered to maximise benefits and minimise harms. Marginalised groups, (including migrants, sex workers, and homeless individuals) typically participate less in screening programmes due to social, cultural and access barriers, and this can contribute to health inequalities. However, these groups usually have higher burdens of disease and associated impacts for primary care. Various models have been developed to improve uptake of screening and subsequent diagnosis and treatment in marginalised groups in primary care. This workshop aims to critically evaluate these and consider practical implementation strategies.

Objectives: - Understand the principles of screening in primary care and the specific access barriers faced by marginalised groups - Understand the advantages and disadvantages of commonly used interventions to improve participation among underserved groups, such as outreach to community locations, reminder-based interventions and self-test kits - Share and learn from real-world examples of screening models for marginalised groups - Co-design practical, context-specific strategies and solutions to improve screening

Teaching method and workshop: Methods Brief presentations, small group exercise, world café. Schedule Introduction (10 mins): Overview of screening for marginalised groups in primary care, including relevant research evidence Group Activity (15 mins): Using participat

Expected outcomes: Attendees will improve understanding of challenges faced by marginalised groups in access and experience of screening in primary care, and models and practical solutions to enhance uptake and linkage to care in marginalised groups.

Conclusion: This workshop will enable attendees to explore the barriers and enablers to primary care screening programmes for marginalised groups, and develop context-specific ideas and solutions to apply to their own context.

Context: Inferior vena cava (IVC) ultrasonography is an increasingly valuable tool for managing patients with chronic heart failure (HF), yet its use in primary care settings is not well described

Objectives: This study aims to evaluate the prevalence of ultrasound-assessed congestion in HF outpatients seen in primary care.

Methods: A cross-sectional observational study was conducted involving all patients diagnosed with HF in five consultation units at our primary care center in Sant Feliu de Llobregat, a city within the province of Barcelona, who agreed

to participate, and they could travel to the centre. A total of 120 patients over 18 years of age were contacted. Collected data comprised sociodemographic factors and cardiovascular clinical characteristics. Ultrasound congestive HF was defined as an IVC diameter ≥21 mm or an inspiratory collapse <50%. Clinical congestion HF was considered present if two or more relevant symptoms worsened (dyspnea, edema, weight gain, jugular vein distention) 1,3. The IVC ultrasonography was performed by doctors from the center trained in 3 sessions of 2 hours each. A descriptive analysis was performed.

Results: Finally, 77 participants were included and 43 excluded due to multimorbidy or mobility problems. Were female 47(61.0%), with a mean age of 80 years. Fifty-one (66.2%) patients had more than two cardiovascular comorbidities, 52(67.5%) had HFpEF, and 21(27.2%) had HFrEF, and 53 (68.8%) had polypharmacy (>5 medications). Ultrasound evidence of congestion was found in 17 participants (22.1%), whereas clinical congestion was identified in only 7 (9,1%).

Discussion: Ultrasound-detected congestion appeared more frequently than clinical congestion during HF follow-up visits in primary care. In older populations, where clinical assessment is often challenging, ultrasonography could have a prominent role easy to perform for evaluating congestion status.

Conclusion: The prevalence of ultrasound-assessed congestion in outpatients seen with HF treated in primary care is high. IVC ultrasonography could be a valuable tool for the follow-up of patients with HF, allowing for early identification of patients at high risk of deterioration. These findings highlight the need for further research.

(1) Université Catholique De Louvain, Brussels, Belgique
(2) Université Libre De Bruxelles, Brussels, Belgique

Context: General practice in French-speaking Belgium currently stands at a crossroads. While the profession once developed in a context of “oversupply,” it is now confronted with the ageing of its workforce. According to the Belgian Federal Health Care Knowledge Centre, in 2000, 24.1% of practising general practitioners were aged 55 or older, compared with 44.3% in 2018. This ageing trend is all the more concerning as it coincides with insufficient renewal of the workforce. The numerus clausus, introduced in 1997, significantly restricted access to medical training and, although quotas have recently been increased, the shortfall persists. In 2024, a 40.7% under-quota of graduates in general practice was observed in the French Community, whereas the Planning Commission targeted 50%. This shortage of young physicians is accompanied by a generational imbalance within representative bodies: a 2021 survey reported that 70% of positions in French-speaking general practice institutions were held by physicians over 40 years old. Taken together, these data point to a clear conclusion: the capacity of French-speaking general practice to represent itself is under threat. In this context, stimulating and supporting the involvement of young general practitioners in the representative institutions of their profession is critical. Such mobilisation is essential to ensure continuity in professional governance and to guarantee that the general practice of tomorrow is shaped by those who will constitute it.

Objectives: To identify barriers and enablers to young GPs’ involvement in representative bodies and to propose concrete actions to strengthen their engagement.

Methods: A workshop at the 2025 Belgian College of General Practice congress invited

participants to identify facilitators, barriers, and actions to enhance young physicians' participation in representative bodies.

Results: The workshop brought together 24 participants with substantial age diversity. The collected data are currently undergoing qualitative analysis. The preliminary analysis suggests that the engagement of young physicians cannot rely solely on individual willingness but requires a supportive and inclusive ecosystem. X

Conclusion: Supporting the engagement of young general practitioners is not only a matter of ensuring the renewal of representative bodies, but also of safeguarding a professional governance that is legitimate, sustainable, and aligned with the contemporary realities of medical practice.

Cap Turó De Can Mates, Sant Cugat Del Vallès, Espagne

Context: Gender bias in medicine is typically discussed in terms of disadvantages for women. However, in Chronic Kidney Disease (CKD), differences in screening habits and GFR estimation formulas might lead to different patterns of underdiagnosis between sexes.

Objectives: To compare the rate of clinical diagnosis (coding) of CKD between men and women who meet the same objective laboratory criteria for the disease.

Methods: Observational study on 988 patients. We selected all patients meeting KDIGO analytical criteria for CKD (GFR < 60 or ACR ≥ 30). We calculated the "diagnosis rate" (percentage of these patients who actually had a CKD code in their electronic health record) and compared it by gender using descriptive statistics.

Results: Sixty-nine patients met the analytical criteria for CKD (42 men and 27 women). Interestingly, women were significantly more likely to be correctly diagnosed (55.6% diagnosis rate) compared to men, of whom only 38.1% had a recorded diagnosis. This occurred despite men and women having similar mean GFR levels (63.9 vs 67.1 ml/min) and albuminuria profiles.

Discussion: Our data reveals a "reverse gender gap" in CKD recognition, where men with renal insufficiency or albuminuria are less likely to be coded as CKD patients than women. This could be related to more frequent healthcare contact by women or a lower perception of fragility in male patients by clinicians.

Conclusion: In our setting, men with objective renal damage suffer from a significantly higher rate of underdiagnosis (61.9%) compared to women. Strategies to improve CKD coding should specifically target the male population to ensure they receive adequate follow-up and preventive care.

Context: Participatory approaches include communities and those working with them in this process, promoting active engagement, shared decision-making, and equity in knowledge generation. Patient and Public Involvement and Engagement and participatory methods are increasingly recognised as valuable tools in general practice service design, research, and training. Their importance is evident in healthcare, where collaboration between patients and professionals are central to improving outcomes. However, many primary care clinicians, educators, and researchers lack

confidence in applying this approach, often compounded by structural barriers such as limited time, resources and institutional support. Common concerns include loss of control, added workload, acknowledging the 'unknown', and fear of tokenism or failure.

Objectives: - Understand the principles and spectrum of participatory approaches, including the "ladder of participation." - Understand how to overcome barriers to participatory approaches and build confidence in using them. - Share and learn from real-world examples - Co-design practical, context-specific strategies and solutions to applying participatory approaches in primary care

Teaching method and workshop: Methods A highly interactive workshop, led by experienced facilitators comprising brief presentations, small group exercise, world café, short video, Schedule Introduction (10 mins): Overview of participatory principles and ladder of par

Expected outcomes: Attendees will better understand participatory approaches, and identify practical ways to use these to enhance engagement, relevance, and impact across general practice, research and educational settings.

Conclusion: This workshop will enable attendees to explore the relevance and value of participatory approaches in primary care research and practice, and develop confidence, ideas and solutions to apply to their own context.

ID 2011- Game on: how to design interactive workshops for learner engagement

Larysa KUPRIIANOVA

Kharkiv National Medical University, Kharkiv, Ukraine

Context: The problem of type 1 diabetes mellitus (DM) remains relevant due to the constantly increasing incidence, the development of complications that lead to loss of work capacity and disability of the population, and due to the high mortality rate in all age groups. Modern literature presents studies on the leading issues of etiology, pathogenesis, clinical and morphological manifestations of type 1 DM, but there is still no established concept of a comprehensive approach that affects the quality of diagnostic and preventive measures.

Objectives: To identify the main risk groups for type 1 diabetes and to propose a comprehensive approach to predicting and preventing the development of this disease in children born to mothers with type 1 diabetes. The study material constitutes the data from medical charts of the development of children from 0 to 16 years old who were born to mothers with type 1 diabetes.

Methods: Anamnestic, statistical.

Results: Data from medical records of children aged 0 to 16 years were analyzed in order to compare the developmental characteristics and nature of morbidity in children born to healthy mothers compared to children born to mothers with type 1 diabetes.

Discussion: It was found that children born to mothers with type 1 diabetes are more likely to suffer from chronic diseases of the cardiovascular and respiratory systems; in 45 percent of observations, additional instrumental methods of research showed the presence of disorders of the immune system. Every second child was classified as a 2nd or 3rd health group due to the chronicity of the process. In 10 percent of children, clinical manifestations of type 1 diabetes mellitus occurred, in 25 percent - transient hyperglycemia was observed.

Conclusion: Considering the aforementioned data, it is crucial to classify children born to women with type 1 diabetes mellitus as ones at risk for the development of type 1 diabetes mellitus, as well as the development of chronic pathologies of the cardiovascular, immune and respiratory systems. Accordingly, such children require additional research and medical examinations for the purpose of prevention, timely detection and treatment in order to prevent the development of chronic pathologies and disability in the future.

(2) C.s. Autol, Autol, Espagne

Context: In primary care, family physicians often face patients whose physical illnesses are deeply influenced by social determinants of health. Managing chronic pain becomes particularly challenging when combined with domestic violence, alcohol misuse, and social vulnerability. This case illustrates how social adversity can shape clinical outcomes and therapeutic responses, creating new challenges for healthcare systems.

Methods: We present the case of a middle-aged woman, a frequent attender in our practice, with a long history of chronic coxalgia that ultimately required bilateral hip prostheses. Beyond her physical illness, she lives in a highly complex social environment marked by domestic violence and lack of family support. She developed alcohol dependence, which progressed to cirrhosis and gastroesophageal varices. During an emergency hospital visit, physicians unfamiliar with her background prescribed opioid analgesics. Since then, she has developed opioid dependence, and attempts to taper and discontinue have been unsuccessful.

Originality: This case highlights the intersection of chronic pain, social adversity, and iatrogenic harm. It shows how lack of continuity of care and limited awareness of context can exacerbate vulnerability, leading to new health problems such as opioid dependence

Lessons learned and future implications: This experience demonstrates that comprehensive care must extend beyond physical treatment and include understanding of the patient's social reality. Continuity of care is essential to avoid inappropriate clinical decisions, and complex cases demand multidisciplinary approaches involving social services and mental health support. Opioid prescribing must be cautious and contextualized, as vulnerable patients face high risk of dependence. Finally, the role of the family physician is not only to treat symptoms but also to defend patient autonomy, ensure fairness in access to care, and foster solidarity in clinical relationships

Discussion: This case emphasizes the need to integrate a biopsychosocial perspective into practice. Although prosthetic surgery improved mobility, unresolved social issues and alcohol misuse perpetuated suffering. Introduction of opioids without contextual knowledge worsened her condition, revealing how lack of coordination between care levels can lead to harm

Conclusion: Chronic pain cannot be managed in isolation from the patient's reality. Family physicians must promote holistic care, ensure continuity, and apply prudent prescribing. Addressing vulnerability requires collaboration across medical, psychological, and social domains to improve outcomes

Context: AI is becoming increasingly visible in primary care, yet much of the current conversation remains limited to efficiency, capacity and technical innovation. These are important, but they don't address the deeper, more human questions many clinicians and leaders are already grappling with: How will AI change the identity of our teams? Who may be

excluded from new digital pathways? What happens to local clinical wisdom ?how do we reconcile the environmental and ethical costs of large-scale digital adoption? These quieter concerns shape trust, cohesion, fairness in ways that often go unnoticed. This workshop provides space to explore these overlooked impacts and consider how leaders can guide AI adoption responsibly, with people and values at the centre.

Objectives: This workshop aims to help leaders explore the human, ethical, and environmental impacts of AI in primary care.Use **Liberty, Equality and Fraternity** to examine autonomy, fairness, and team cohesion in the context of digital transformation.Equip leaders with practical strategies to implement AI responsibly while preserving team identity, inclusion, and patient trust.

Teaching method and workshop: Participants engage in short provocations, scenario-based discussions, and small-group mapping exercises. The session encourages reflection, dialogue, and collaborative problem-solving, allowing leaders to consider how AI affects teams, patients, and the

Expected outcomes: Participants will better understand how AI affects team dynamics, equity, and patient trust. They will leave with actionable strategies to lead responsible, values-driven digital transformation

Conclusion: This workshop helps leaders move beyond the hype, addressing the hidden challenges of AI. By focusing on autonomy, fairness, and cohesion, leaders can implement digital innovation that strengthens, rather than weakens, the human foundations of primary care.

ID 1790- General Practice and Judicial Expertise: A Nineteen-Year Experience from Algeria

Gabriele ANGELONI

Simccp, Fiumicino, Italie

Context: Chronic diseases require continuous, patient-centred care, yet access to follow-up is often limited by organisational and social barriers. Telemedicine is promoted as a tool to improve continuity and equity of care, but real-life evidence from pathways involving community and primary care physicians is limited. At the AOU Policlinico Umberto I (Rome), a Day Service of predictive, gender-specific medicine and chronicity coordinates an integrated pathway for adult chronic diseases in collaboration with community and primary care medicine, using video consultations for follow-up.

Objectives: To evaluate feasibility, acceptability and perceived impact of this telemedicine pathway for adults with chronic conditions, and to identify factors associated with digital difficulties.

Methods: We conducted a prospective cohort including adults with metabolic syndrome, diabetes mellitus, osteoporosis, arterial hypertension, asthma, COPD and long-Covid followed through scheduled televisits between September 2023 and July 2024. Clinical and organisational data were collected, together with Patient-Reported Experience Measures (PREMs). Difficulties in using the technology were analysed by age group and presence of caregiver support.

Results: A total of 120 televisits were performed. Telemedicine was highly accepted: 96% of patients expressed willingness to continue and 97% did not require an additional in-person visit. PREMs showed high satisfaction: 76% of patients felt more confident in managing their condition, and over 90% perceived improved symptom control and a better relationship with their physician. Technological difficulties were concentrated among patients over 60 years without caregiver support, who had a significantly higher risk of problems in connecting and interacting online.

Discussion: Telemedicine within an integrated chronic care pathway can strengthen patient empowerment, continuity of care and the therapeutic alliance, while reducing potentially avoidable face-to-face visits. At the same time, age-related digital divides and lack of family or

community support may limit access for the most vulnerable, risking new inequities.

Conclusion: Telemedicine appears to be an effective and well-accepted tool for chronic disease management in a Primary Care–Community Medicine context. Scaling up such models requires investment in digital literacy, technical support and structured links with territorial services, in line with national and regional policies, so that telemedicine promotes equity and humanism in primary health care.

Context: Post-electric shock cardiothoracic symptoms in a 25-year-old female with normal cardiac evaluation.

Methods: A 25-year-old woman, with no significant medical history, presented to Primary Healthcare following an occupational electric shock two days prior. Since the incident, she has experienced chest oppression, asthenia and bradykinesia. On physical examination, cardiopulmonary auscultation was rhythmic without murmurs or additional sounds; transient tachycardia resolving within seconds. No entry or exit point of the electrical current were observed. An electrocardiogram was performed showing sinus rhythm at 80 bpm, narrow QRS, no conduction abnormalities and no repolarization changes. Three days later, chest pain persisted and aphonia appeared without odynophagia. Physical examination revealed normal cardiopulmonary auscultation, normal oropharynx and intense tenderness on palpation over the sternum and ribs. A Cardiology e-consultation was requested and chest and sternum X – rays were performed with no acute pathological findings. During Cardiology consultations, a new ECG showed sinus rhythm at 67 bpm, PR interval 114 ms without clinical relevance, and a transthoracic Doppler echocardiogram revealed no abnormalities.

Originality: Electrical shocks can produce cardiovascular, neurological and musculoskeletal symptoms of varying severity. In this case, the patient experienced chest pain, asthenia, bradykinesia and aphonia following a low-voltage electrical shock, without detectable electrical or structural changes. The case highlights the usefulness of e-consultations for rapid cardiology assessment and follow-up in Primary Healthcare.

Lessons learned and future implications: This case demonstrates the importance of comprehensive evaluation and follow-up after electrical injuries, even in the absence of abnormal findings in tests performed in Primary Healthcare. Persistent symptoms may require interdisciplinary assessment, and the role of the Primary Care physician is essential for monitoring and coordinating with specialists.

Discussion: Electrical injuries present a wide spectrum of clinical and electrical manifestations, ranging from asymptomatic to life-threatening. In this patient, chest pressure and bradykinesia were not explained by electrical or structural alterations. This confirms that not all symptoms following an electric shock are of cardiological origin, highlighting the importance of thorough patient evaluation.

Conclusion: Comprehensive Primary Healthcare, combined with specialist collaboration via e-consultations, ensures proper management of patients after electrical injuries. Even when tests are normal, symptoms monitoring and follow-up are essential for patient reassurance and preventing complications.

(1) University Of Leeds, Leeds, Royaume-Uni
(2) Ifsma, University Of Ioannina, Ioannina, Grèce
(3) Waynaykay Movement/ Cimf/ Mexican Federation Of Family Medicine Specialists, mexico City, Mexique

Context: Family medicine is a fast-paced, high-pressure environment with limited opportunities to share techniques for managing workload and stress in a safe, supportive setting. Real-world scenarios, such as handling difficult patients (Bailey, Marin and Bangs, 2023), are explored using evidence-based tools. These challenges can affect clinicians' physical and mental health. A simulated space for discussion and learning helps participants develop strategies to support their wellbeing while maintaining high-quality care.

Objectives: Identify and prioritise competing clinical demands in a simulated clinic. Demonstrate effective time-management when balancing appointments, results, interruptions and unexpected events. Respond as a team to acute situations in primary care. Reflect on personal strengths and growth areas, and share techniques for managing difficult days. For students and trainees, the simulation provides added clinical experience in a safe, supported environment.

Teaching method and workshop: Groups will be formed at the start with a mix of students, trainees and qualified family physicians. Multiple teaching methods will be used, and the session will mimic a typical clinic. A non-linear PowerPoint will guide participants, with the clinic's di

Expected outcomes: 1. Increase competence and confidence in clinical-workflow management and common challenging scenarios 2. Through application and shared reflection, identify tools and techniques that will help you manage your own clinic

Conclusion: This interactive workshop offers an engaging way to prepare future and current GPs for the challenges of primary care. Designed by students and early-career GPs, it reflects real-world pressures. By simulating a dynamic clinic with acute events, rapid decision-making, and reflective practice, participants can build confidence, sharpen prioritisation skills and better understand how to manage the complex demands of family medicine while providing compassionate, comprehensive care whilst maintaining their wellbeing.

ID 485- Generic dispensing rates for substitutable drugs prescribed by general practitioners compared with other private ambulatory specialists: A study based on a French national reimbursement database

Nena KOPCAVAR GUCEK

Medical Faculty, University Of Lčjubljana, Slovenia, Ljubljana, Slovénie

Context: Violence was recognized as a major and growing health threat by a 1996 World Health Organization resolution. While workplace violence occurs across sectors, healthcare is particularly vulnerable, accounting for about a quarter of all incidents. In the EU-27, incidence reaches 15%, and surveys confirm health workers facing one of the highest risks. Firearm-related violence is increasingly acknowledged as a public health issue, though physicians' role in prevention remains debated.

Methods: Following two premeditated murders of physicians in 2007 and 2017, the Medical Chamber of Slovenia established an interdisciplinary task force. Its mission includes raising awareness, collecting data on violent incidents, proposing legal amendments, offering workshops, and counselling victims. In 2025 (until Dec 1), four workshops were conducted, members lectured at conferences, and participated in a round table. One notable case involved a rural family doctor. After declining a patient's requests for referrals or sick leave, the patient placed a gun on her desk.

The doctor, fearing for herself, staff, and family, sought guidance. Anxiety affected her work, and she hesitated to report the incident, unsure if the weapon was real.

Originality: A 2017 online survey found 17% of respondents experienced physical violence and 99% (N = 1096) psychological violence. Firearm exposure was rare. Following a 2017 shooting of a urologist in Izola Hospital, no further firearm assaults occurred. This case, where the weapon was displayed but unused, required careful analysis and development of guidance for medical staff.

Lessons learned and future implications: The task force's chief police inspector advised the doctor to report the incident, emphasizing that any firearm-related threat must be reported, regardless of authenticity.

Discussion: Firearm policies differ globally. A review by McGuire et al. found weapons prevalence in healthcare from 0.4% to 26.3% (1984–2023). Prevalence was 2.0% among hospital entrants and 1.6% in emergency departments. US hospitals are considered "hot zones," yet firearm screening in primary care remains controversial and policy-dependent.

Conclusion: Healthcare facilities must remain safe. Policymakers should adopt legislation protecting patients and staff from firearm violence. Strengthening healthcare workers' capacity to manage threats is essential and primarily the responsibility of employers.

Melike AKCAKAYA, Meryem ASKIN, Zeynep ASLAN

Izmir City Hospital, Izmir, Türkiye

Context: With global population ageing and increasing multimorbidity, home care services have become a vital part of primary healthcare. In Turkey, home care targets individuals who are bed-bound, device-dependent, functionally limited, elderly or unable to reach health facilities. Aligned with WHO principles, the national system is organized through a central call center, provincial coordination units and multidisciplinary home-care teams. Since the 2023 restructuring, the system has grown rapidly: in one tertiary region, more than 2000 patients have been served, and around 700 are under active follow-up. Teams include physicians, nurses, emergency medical technicians/home-care technicians, and when needed, physiotherapists, social-care liaisons, tele-health staff and collaboration with public safety services. Provided care includes medical examinations, wound care, sampling, catheter and enteral access procedures, injections, chronic disease monitoring, physical therapy, palliative support and remote-care technologies. This workshop explores how Turkey's model reflects the WONCA 2026 values of liberty (autonomy), equity (fair access), fraternity (community solidarity) and humanism (dignified, compassionate care). Participants will share national experiences, compare systems and co-develop adaptable, transferable solutions for strengthening home-based care.

Objectives: Understand the structure, team composition, and service scope of the Turkish home-care model. Analyse how home-care practices promote autonomy, equitable access, solidarity and human-centered care. Compare international home-care models and identify shared challenges. Develop practical improvement strategies for primary-care-based home-care services

Teaching method and workshop: Mini-lecture on the Turkish model Multidisciplinary team role analysis Case-based small group discussions (COPD, dementia, terminal cancer) Role-play on first home visit, consent and safety planning Mapping equity gaps International experience sharing 10

Expected outcomes: Participants will gain practical insights into an adaptable team-based home-care model, acquire tools for triage and home-visit planning, and co-create strategies to strengthen equity and humanism in primary care. Cross-country dialogue will support colla

Conclusion: Turkey's home-care model demonstrates how accessible, multidisciplinary and person-centered services can uphold

WONCA's core values. This workshop provides a dynamic platform for international comparison and the development of transferable improvements in home-care practice.

University Of Opole, Opole, Pologne

Context: Despite physicians' high medical competence, misunderstandings frequently occur in doctor–patient relationships. These misunderstandings often stem from communication breakdowns, especially when both sides perceive different priorities during the visit. Such misalignments can diminish satisfaction with care.

Objectives: The aim of the study was to compare which elements of a primary care visit are considered most important by patients and by physicians. In addition, we examined whether any discrepancies exist between the two groups in their priorities and experiences.

Methods: An anonymous survey (paper-based in primary care clinics and online) was conducted from June to November 2025. A total of 82 patients and 49 physicians participated. An author-designed questionnaire on communication and expectations during the visit was used, featuring questions rated on a five-point Likert scale. Comparative analyses were performed between the responses of the two groups.

Results: Both groups assigned the highest importance to an accurate diagnosis, effective treatment, and a clear explanation of the health condition. Physicians were more likely to indicate empathy, courtesy, and eye contact as very important. Patients, in turn, placed greater emphasis on being informed about treatment costs and practical information related to treatment, costs, and next steps after the visit. Physicians rated their own communication skills higher than patients did. Conversely, patients reported adhering to recommendations more often than physicians believed.

Discussion: Both parties share similar intentions. However, differences in the prioritization of expectations and in self-assessment of communication can lead to dissatisfaction and frustration. Each side may not fully recognize the other's priorities.

Conclusion: Understanding and accounting for mutual expectations regarding communication can improve the quality of the doctor–patient relationship and enhance the effectiveness of treatment. Primary care practitioners should balance the factual and relational aspects of the visit and ensure that the patient understands the diagnosis and plan of action.

(3) Ffr, Paris, France
(4) Université Montpellier Nimes, Nimes, France

Context: Concussions represent a growing health issue in amateur rugby due to the potential neurological sequelae associated with repeated head injuries. To structure their management, the French Rugby Federation introduced the "blue card protocol" in 2019, which is requiring a minimum ten-day before returning to play. The real-world application of this protocol remains poorly documented.

Objectives: This study aims to evaluate post-concussion behaviors among amateur rugby players in the Occitanie region and assess their compliance with federal recommendations.

Methods: We roll out a quantitative descriptive study using an online questionnaire distributed to senior licensed players between September and November 2024. The primary evaluation

criterion was the duration of rest following a concussion, compared with the 10-day standard using a Wilcoxon test (non-parametric sample). Secondary criteria involved the implementation of the blue card, access to medical care, and players' level of knowledge.

Results: A total of 411 responses were collected, including 202 players who reported concussions since 2019. Among them, 95 did not take heed of any rest period after the injury, and the average rest duration was estimated at 8.5 days. The difference between this result and the recommended 10-day rest period is significant. The blue card was applied in 26.5% of cases. The data were comparable across all levels. Meanwhile, only 40% of players consulted a healthcare professional, and 30% reported having no knowledge of concussion risks but expressed a desire for better information. More than 75% would consider consulting their family doctor in case of a future concussion.

Discussion: The results highlight a concerning gap between official recommendations and real-world practices, both in rest duration and in the use of the regulatory protocol. These discrepancies can be explained by a rugby culture that tends to minimize symptoms, a lack of awareness, and limited access to medical services.

Conclusion: The leading role of the general practitioner appears essential in the prevention and support of players. Strengthening the training of stakeholders in amateur rugby (players, staff, referees) is a key lever to improv concussion management.

Mohamed Haithem BEN HAJ SALAH, Mondher KARRAY, Marouen HAFSA

Stmgf, Monastir, Tunisie

Context: Le prédiabète constitue un problème croissant de santé publique, en particulier dans

les pays à revenu intermédiaire. En Tunisie, les médecins de première ligne sont en première position pour le dépistage et la prévention, mais les données nationales récentes restent limitées. L'étude TUN-PREDIAB a été mise en place pour estimer la prévalence du prédiabète en soins primaires et identifier ses principaux facteurs prédictifs.

Objectives: Estimer la prévalence nationale du prédiabète chez les consultants de première ligne ; Décrire le profil clinique et métabolique des patients ; Identifier les facteurs associés au prédiabète ; Explorer l'influence des habitudes nutritionnelles, notamment l'adhésion au régime méditerranéen.

Methods: Étude transversale descriptive menée du 2 mai au 9 septembre 2025. Ont été inclus les patients ≥18 ans consultant en médecine générale, médecine de famille ou médecine du travail, après consentement éclairé. Ont été exclus : diabète connu, traitements influençant la glycémie, grossesse, comorbidités sévères. Les données ont été collectées via la plateforme sécurisée DACIMA Clinical. L'HbA1c a été utilisée pour classer les patients (normale, prédiabète, diabète). Des analyses statistiques univariées et bivariées ont évalué les associations (seuil de significativité $p < 0,05$).

Results: Au total, 6 470 patients ont été recrutés dans les 24 gouvernorats ; 5 180 ont été retenus dans l'analyse finale. La prévalence du prédiabète atteint 63,3 % dans la population étudiée. Une proportion de 79 % présente un IMC ≥25 kg/m² ; la moitié des prédiabétiques est obèse. Le prédiabète est significativement associé à l'âge croissant ($p < 0,001$) et au niveau scolaire ($p = 0,025$). Aucun lien significatif n'a été retrouvé concernant l'adhésion au régime méditerranéen ($p = 0,161$).

Discussion: Les résultats montrent un fardeau métabolique majeur en soins primaires tunisiens. L'excès pondéral, très fréquent, apparaît comme un déterminant majeur. La couverture géographique exhaustive renforce la robustesse des estimations.

Conclusion: Le prédiabète en première ligne en Tunisie atteint un niveau alarmant, nécessitant un renforcement urgent des stratégies de dépistage, de prévention et d'éducation thérapeutique pour limiter la progression vers le diabète de type 2. Ces résultats appellent à des interventions ciblées et à des recherches complémentaires pour adapter les politiques nationales de santé.

ID 1009- Glycemic control rather than Opiates reduces pain in poorly controlled diabetes with Chronic degenerative disc disease

Agata KULKOWSKA, Katarzyna BĘBNOWICZ, Paweł SZAJKOWSKI, Ewa GANCEK, Patrycja SCHINK, Monika DRZAZGA

Univeristy Of Opole, Opole, Pologne

Context: Thymoma is a rare neoplasm of the thymic epithelium, representing a small proportion of thoracic tumors. Its clinical course is often indolent, but local invasion and association with paraneoplastic syndromes, such as myasthenia gravis or neuropathies, complicate diagnosis and management. We present a case of a 57-year-old male with a history of long-term occupational exposure to toxic substances, who was diagnosed with thymoma following routine screening and evaluation for chronic lower limb sensory disturbances and muscle weakness.

Methods: A comprehensive diagnostic approach was undertaken, including detailed history, physical examination, laboratory tests, and imaging (chest X-ray and CT). Given the atypical neurological symptoms and well-controlled diabetes, the diagnostic process was expanded to include paraneoplastic syndromes. Surgical resection of the mediastinal mass was performed, followed by histopathological confirmation of type AB thymoma with capsular and adipose tissue invasion. The patient received adjuvant radiotherapy and subsequent resection of a large subcostal lipoma.

Originality: This case highlights the diagnostic complexity of thymoma presenting with paraneoplastic neuropathy in a patient with well-controlled diabetes and significant occupational exposure. The case underscores

the importance of considering paraneoplastic syndromes in the differential diagnosis of neuropathy, even in patients with established risk factors such as diabetes.

Lessons learned and future implications: An interdisciplinary and holistic approach, including preventive screening and thorough evaluation of atypical symptoms, is essential for early detection of rare malignancies. The case demonstrates the pivotal role of the family physician in recognizing red flags and initiating appropriate diagnostics. Future clinical practice should emphasize occupational health, regular screening, and awareness of paraneoplastic manifestations.

Discussion: The presented case illustrates the challenges in diagnosing thymoma, particularly when initial symptoms are nonspecific and may be attributed to more common conditions. It also emphasizes the need for vigilance regarding occupational risk factors and the value of a multidisciplinary team in patient management. Early diagnosis and intervention can significantly improve prognosis and enable curative treatment.

Conclusion: This case demonstrates that prompt, interdisciplinary evaluation and preventive care can lead to the early diagnosis and successful treatment of thymoma. The family physician's role is crucial in identifying atypical presentations and ensuring comprehensive patient care, ultimately improving patient outcomes.

Context: Hypertension is a major chronic condition in primary care, with e-health adoption varying widely across countries. While digital tools for monitoring blood pressure and delivering remote care are evidence-based, their use is influenced by resources, workforce capacity, policies, and cultural factors. The Hypertension Galaxy Lab adopts a systems-thinking approach, using a galaxy metaphor to examine national differences in e-health for hypertension management, while encouraging collaborative learning among primary care professionals.

Objectives: 1. Describe and compare e-health practices in hypertension treatment across different countries. 2. Create a "health system galaxy" visualizing their country's resources as "stars," digital tools as "satellites," barriers as "black holes," and collaboration opportunities as "orbits." 3. Identify common facilitators and challenges in implementing e-health solutions for hypertension management. 4. Identify potential areas for international cooperation or future initiatives involving multiple countries.

Teaching method and workshop: The workshop includes a brief theoretical overview, metaphor-based instruction, and small-group teamwork. Participants work in diverse international groups using visual templates to examine and compare system components, fostering active participation and

Expected outcomes: Participants will identify opportunities for improvement and build cross-country connections. The workshop will develop a collective map of shared facilitators, barriers, and ideas for future implementation or research.

Conclusion: This workshop makes complex system variability simple and engaging,

providing practical insights and collaboration opportunities for primary care and global e-health in hypertension management.

Context: Rural family medicine offers a model of care different from urban practice. In small villages where the doctor's office opens only a few days per week and healthcare professionals become a stable reference for patients, relationships naturally deepen. As a third-year family medicine resident in a rural community, I followed an older male patient for several years. His frequent visits and personal circumstances show how continuity of care in rural settings goes beyond clinical practice and becomes a meaningful human bond.

Methods: From the beginning of my residency, the patient attended almost weekly, taking advantage of the few days we were present in the village. He was always polite and grateful, reflecting the familiarity of rural care, where community interactions extend beyond the consultation room. During these years, I accompanied him through minor complaints and complex situations. Early in my training he presented with fulminant hepatitis and marked jaundice, which resolved spontaneously. I also witnessed the emotional burden he carried as caregiver for his wife with Alzheimer's disease. This summer he presented with macroscopic hematuria. The diagnostic work-up revealed stage IV metastatic bladder carcinoma. Despite appropriate referral and palliative support, he died four months later. Accompanying him during this final stage affected me deeply, not only as a doctor but as someone woven into the fabric of this small community

Originality: This case highlights the unique relational depth of rural primary care, where long term follow-up and community proximity create emotional and ethical challenges rarely seen in urban settings. The permeability between clinical encounters and community life shapes a distinctive professional experience

Lessons learned and future implications: His death was the first that profoundly affected me as a resident. I learned that rural medicine requires skills seldom taught: managing grief, balancing closeness with boundaries, and recognizing proximity as both therapeutic and vulnerable. These insights will shape my future practice, especially in end-of-life care and community-centred approaches

Discussion: This case underscores the need for residency programs to integrate emotional preparedness, continuity skills and rural competencies

Conclusion: This experience reaffirmed that rural family medicine is woven through humanity, closeness and community, and the patients can profoundly shape a clinician's professional identity

Corresponding author: Irlanda Gil Fernández, irlandagil@gmail.com

(4) The Israeli Society Of Lifestyle Medicine. Israeli Association Of Family Physicians., Ramat Gan, Israël
(5) Lithuanian University Of Health Sciences Faculty Of Public Health, Kaunas, Lituanie

Context: Lifestyle Medicine (LM) has gained wide visibility in recent years, yet misconceptions persist among healthcare professionals. LM is often confused with

practices with non-evidence-based interventions. This conceptual ambiguity contributes to inconsistent implementation in clinical settings. At the same time, the growing burden of chronic diseases highlights the need for primary care teams to integrate structured, evidence-based lifestyle interventions. Family medicine (FM), with its holistic, person-centred approach and long-term clinical relationships, is uniquely positioned to deliver LM effectively. Clear definitions and access to credible training resources are essential for ensuring quality and consistency.

Objectives: By the end of the workshop, participants will be able to: Define what LM is and distinguish it clearly from what it is not. Describe the six foundational pillars of LM and the evidence base supporting each. Understand how LM principles align with and enhance core competencies in FM. Identify existing high-quality LM training programmes and resources appropriate for clinical practice.

Teaching method and workshop: The workshop will combine a short introductory presentation, small-group discussions, and case-based interactive exercises. Evidence summaries will be presented through real-world examples, followed by guided reflection on their application in primary car

Expected outcomes: Participants will gain a clear and evidence-based understanding of LM, increased confidence in differentiating it from non-scientific practices, and practical tools for applying LM principles in routine clinical encounters. They will leave with a list of

Conclusion: Clarifying LM and grounding it in robust evidence is essential for strengthening its role. This workshop provides practical knowledge, structured resources, and clinical frameworks that enable FM practitioners to integrate LM confidently and effectively.

Marilena CONSTANTIN

Victor Babes Diagnosis $treatment Centre, Bucharest, Roumanie

Context: According to literature data patients with type 2 diabetes have 20% higher risk to develop leukemia

Methods: Case presentation A 70 years old male patient who is monitoring for type 2 diabetes with micro and macrovascular complications since 2016 presented lymphomonocitosis in 02.2024 In 07.2024 the patient was diagnosed with chronic lymphocitic leukemia The patient asociates kidney cronic disease , hepatites with virus C treatet with telaprevir, hypertension, dyslipidemia, obesity, right nephrectomy for hydronephrosis

Originality: To think about that diabetes mellitus could be a risk factor for leukemia and chek this in literature

Lessons learned and future implications: We always should take in consideration the comorbitities of our patients (diagnose, treat them, reffer to other specialist)

Discussion: Discussion: The question related to this patient was is diabetes mellitus a risk factor for leukemia or was this association a coincidence Some literature data discuss about a higher risk for leukemia and other blood cancer(mieloma, non hodgkin lymphoma) in patients with diabetes. There were presented as possible mechanism an increase of glucose uptake in cancer cells in pacients with hyperglycemia but also chronic inflamation, insulin resistance which induce cancer cell growth and proliferation. Other meta-analysis did not found a statistically significant ralationship It is also impotant the options for treatment in these patients

Conclusion: This presenetation discuses about a possible association between leukemia and diabetes mellitus. We shoudn/t focus only to keep the sugar blood in normal range but we

should see the patient with diabetes and comorbidities

Carmen DE SANTIAGO, Paolo Augusto ROMERO MERINO, Carlos Eduardo GOMES RODRIGUES CORREIA, Rosa María GONZALEZ LÓPEZ, Ayeiza María FELIPE LEMES

Centro De Salud Arrabal De Portillo, Valladolid, Espagne

Context: Erythema multiforme (EM) is an acute,immune-mediated skin reaction most frequently associated with herpes simplex virus (HSV) infection or, less commonly,with medications. Its polymorphic presentation, characterized by erythematous or vesiculobullous lesions, often leads to diagnostic confusion in primary care,particularly when mimicking drug eruptions or fungal infections. This case highlights the importance of clinical reasoning and multidisciplinary coordination in the evaluation of recurrent EM triggered by HSV infection.

Methods: A 42-year-old woman presented with a 4-day history of erythematous, non-pruritic, target-like lesions predominantly on the upper limbs and face.She had been under empirical treatment with itraconazole and bilastine at home without improvement. The patient reported previous similar episodes approximately eight months and six months earlier. Physical examination showed erythematous and partially vesicular lesions with some painful evolution but no systemic symptoms.Vital signs were stable.Initial management included intramuscular methylprednisolone 80 mg, achieving partial improvement.After dermatology consultation, the lesions were identified as erythema multiforme, most likely related to herpes simplex virus infection.Oral valaciclovir and topical corticosteroids were prescribed, with complete resolution within days.

Originality: This case emphasizes the diagnostic difficulty of distinguishing EM from drug-induced eruptions or infectious dermatoses in primary care.The recurrent nature,clinical morphology,and response to antiviral therapy supported a viral etiology.It demonstrates how misinterpretation of EM as mycosis or allergic reaction can delay definitive treatment and increase unnecessary exposure to antifungals or corticosteroids.

Lessons learned and future implications: Family physicians should consider herpes-associated EM in cases of recurrent erythematous or vesicular eruptions unresponsive to conventional antifungal or antihistaminic treatment. Establishing the viral etiology allows for targeted management, preventing misdiagnosis and unnecessary pharmacologic interventions.

Discussion: Recognition of herpes-associated EM requires awareness of its recurrent and polymorphic nature.In primary care,a careful clinical history and observation of lesion evolution are key to identifying the underlying cause.Early antiviral therapy can shorten the duration of outbreaks and reduce recurrence frequency,improving patient quality of life.This case also highlights the value of close communication between primary care and dermatology for diagnostic confirmation.

Conclusion: Recurrent herpes-related erythema multiforme represents a diagnostic challenge in primary care.This case underscores the relevance of continuous clinical reassessment,appropriate specialist referral,and antiviral management to achieve optimal outcomes.

ID 278- Healing through art: an experience report on a handicraft group for older adults

Juliette GUARY, Florence ADELINE-DUFLOT, Alice TORNO-BOZEC, Caroline JEHANNO

Université De Rennes, Rennes, France

Context: “Leadership” skills first appear in the French professional framework for general practice (GP) in 2025. Leadership already exists in the Canadian physician competency framework ‘CanMEDS’ and has many

definitions in the literature. The need for training in “distributed leadership” for postgraduate students or residents in GP has been identified in several recent studies.

Methods: A workshop will be offered at the National Congress of GP in December 2025 (CNGE). This workshop is open to all congress participants who wish to attend (students, general practitioners, patients, other healthcare professionals and teachers). Four general practitioners who teach at the University of Rennes will facilitate the workshop. The objectives of the workshop are as follows: To compare participants' views on leadership skills. To develop a common understanding of this concept. To gather concrete examples of professional situations involving leadership. To identify existing training resources and those that need to be developed. To determine the expected level and assessment criteria in “leadership” for GP residents. A summary of this workshop will be produced.

Originality: This is a review of the first French reflection on leadership skills for GP residents. There is currently no specific leadership training at our university. There is a emerging dynamic that questions the definition of this competency and the possible teaching methods in GP residents’ training.

Lessons learned and future implications: The workshop summary will improve the development of a leadership training program currently underway at the University of Rennes (France).

Discussion: The English word “leadership” is currently a subject of debate among teaching general practitioners, particularly because of its managerial connotations. We seek to examine the more humanistic aspects of this concept in order to define the new role of French general practitioners, particularly within primary care teams.

Conclusion: Innovative leadership training is essential for the training of future general practitioners. Agreeing on a definition and teaching methods would enable training programs’ harmonisation in France.

ID 2297- Health certification and sick leaves in the practice of Family Medicine in Brazil: gaps and paths to improvement.

Leyla ASLANKAYA, Ozan Emre ELIACIK, Vildan MEVSIM

Dokuz Eylül University Faculty Of Medicine, Department Of Family Medicine, Izmir, Türkiye

Context: Basal cell carcinoma (BCC) is the most common skin cancer, progressing slowly with low metastatic potential but significant local tissue destruction. Timely diagnosis is essential, but patients often delay care when chronic lesions are attributed to trauma or considered benign. Older adults, particularly those who avoided healthcare during the COVID-19 pandemic, may present with advanced disease. This case illustrates how a persistent lesion initially linked to trauma evolved into BCC and was recognized during a routine primary care visit.

Methods: A 71-year-old man presented with low back pain and no significant medical history. He requested fusidic acid for a wound on his chest, attributing it to trauma five years ago. The lesion, a partial avulsion of a nevus, had progressively enlarged. Due to pandemic-related concerns, he avoided medical care and self-treated intermittently. Physical examination revealed a large ulcerated mass with irregular borders on the chest. Given the lesion's chronicity and morphology, malignancy was suspected, and the patient was referred for dermatologic evaluation. Histopathology confirmed BCC. Excision was performed with clear margins, and recovery was uneventful.

Originality: This case highlights how trauma can obscure, rather than cause, malignant transformation. The patient’s misattribution of the lesion to trauma, combined with delayed healthcare-seeking during the pandemic, led to delayed diagnosis. It emphasizes the importance of incidental primary care encounters in detecting significant pathology.

Lessons learned and future implications: Persistent or non-healing lesions, especially those linked to prior trauma, should be

carefully evaluated. Primary care physicians should incorporate targeted skin exams during visits, ask about chronic wounds, and refer for biopsy when malignancy is suspected. Public health messaging should address the impact of delayed healthcare during pandemics.

Discussion: The lesion's clinical features—ulceration, irregular borders, and prolonged duration—were consistent with advanced BCC. Literature shows an increase in delayed cancer diagnoses during the pandemic. This case reinforces the importance of vigilance in primary care to detect skin malignancies early and refer for timely specialist care.

Conclusion: Non-healing skin lesions should never be dismissed as trauma-related without proper evaluation. Primary care plays a key role in early detection of skin cancers like BCC through opportunistic examination, timely referral, and patient education to prevent delay.

Context: Primary care operates closest to communities and plays a critical role not only in service delivery but also in shaping research priorities. Abstracts presented at international conferences offer insight into thematic trends, emerging needs, and knowledge gaps in general practice. WONCA Europe Conferences are a key source for understanding how primary care communities approach equity, fairness, and social justice over time. Aligned with the theme of the 30th WONCA Europe Conference, this study aimed to assess the frequency and thematic distribution of the terms “equity” and “inequity” across previous conference abstract books.

Objectives: To analyse how often equity-related concepts appear in WONCA Europe scientific outputs (2008–2024) and to identify the primary themes associated with these terms.

Methods: In November 2025, past conference archives on the official WONCA Europe website were screened. Available PDF abstract books were searched for the terms “equity” and “inequity” across all submission types, including workshops, oral presentations, short communications, posters, and keynotes. Mentions in titles, keywords, or main text were included.

Results: Among 15 conferences held between 2008 and 2025, abstract books from 11 were available; due to a technical issue, 2018 was excluded, resulting in analysis of 10 books (2008, 2015–2017, 2019–2024). The term “equity” appeared in all 10 books, while “inequity” appeared in 9/10. “Inequity” became more prominent after 2008 and increased notably from 2015 onward, with further growth during and after the COVID-19 pandemic. Across these conferences, around 100 abstracts referenced equity-related concepts. Recurring themes included social determinants and socioeconomic inequalities; migrants, ethnic minorities and vulnerable groups; gender equity and women’s health/leadership; digital health and digital divides; planetary health and climate-related disparities; primary care organisation and financing; and education and advocacy on health equity, racism and implicit bias.

Discussion: The consistent presence of equity-focused themes and the growing visibility of inequity-related discussions reflect an evolving awareness within European primary care research.

Conclusion: Equity has remained a stable part of WONCA Europe’s scientific agenda, while increasing attention to inequity and structural disparities suggests alignment with the 30th conference theme—liberty, equity, fraternity, and humanism—and highlights equity as a core and strengthening priority for the future of primary care research.

ID 965- Health Inequalities and Drug Misuse Deaths in Scotland: Data Driven Insights for General Practice Intervention

Yael GILLERMAN, Lior ZADA

Clalit Healthcare Services, Tel Aviv District, Tel Aviv, Israël

Context: Primary care (PC) physicians are uniquely positioned to respond to acute community health needs during disasters. Hurricane XXX struck XXX, causing widespread infrastructure damage, displacement, and disruption of essential services. A small multidisciplinary medical team was deployed to support affected communities. This presentation describes the experience of a family-medicine–led mission, highlighting the role of PC in addressing immediate and emerging health needs in a low-resource, post-disaster environment.

Methods: The deployment included three physicians (two PC physicians), two social workers, and a team leader. Over 14 days, the team delivered mobile primary care services, adressing medication shortages, and logistical challenges. Data were collected through field logs, structured observations, daily team debriefings. Qualitative analysis identified recurring themes regarding health needs, system gaps, and team functioning in unstable conditions

Originality: Unlike large-scale humanitarian missions, this deployment relied on a small, agile team working in remote areas with limited infrastructure. The presentation provides firsthand insights into how primary care-trained clinicians can rapidly adapt their scope of practice, provide person-centered care even in unstable conditions. It emphasizes the critical and often under-recognized leadership role of PC physicians in disaster response.

Lessons learned and future implications: Core lessons: value of PC skills—triage, chronic and acute disease management, mental-health support, and preventive care—in disaster settings. importance of flexibility, cultural humility, and close collaboration with local health providers. ability to avluate and treat medical situattions in a wide range of health and sickness Future implications include developing training modules for family physicians on disaster medicine, creating rapid-deployment frameworks for small teams, and strengthening international partnerships for coordinated responses.

Discussion: This reinforces that disasters generate not only acute injuries but also significant primary care needs: exacerbations of chronic illnesses, medication interruptions, infectious disease risks, and psychosocial distress. Family physicians can uniquely bridge acute care and continuity care, ensuring holistic, community-based response strategies. The findings suggest that even small teams can have substantial impact when guided by PC principles.

Conclusion: The XXX mission underscores the clinical versatility and leadership capacity of PC physicians in disaster response. Strengthening the integration of primary care into disaster preparedness frameworks can enhance community resilience and improve health outcomes in future crises.

ID 856- Health Intervention for Patients with Increased Cardiovascular Risk

Lucas ABREU CAVERSAN, Ângela PAVEGLIO TEIXEIRA FARIAS, Rosa LEVANDOVSKI, Tailia REGINATO MARTINS, Matheus BÜTTNER BORGES

Grupo Hospitalar Conceição (ghc), Porto Alegre, Brésil

Context: The care of individuals with type 2 diabetes (DM2) requires an interprofessional approach to ensure correct prescription, disease understanding, adequate nutrition, adherence to treatments, and reduction of complications. DM2 treatment should be intensive during periods of disease decompensation, aiming to improve glycemic control, primary or secondary prevention of cardiovascular outcomes, and reduction of target organ damage.

Methods: We present the case report of a 78-year-old woman, hypertensive, obese, diabetic

for over 30 years, with polyneuropathy and macro and microvascular complications (ischemic heart disease, proliferative diabetic retinopathy, and microalbuminuria). A review of medical records was conducted with data from 2016 to 2025. From 2016 to 2022, she had 7 medical consultations. Progressively higher glycated hemoglobin (HbA1c) levels were observed. It was used sulfonylureas, biguanides, and basal insulin. The patient suffered a myocardial infarction in 2022. She was received by an interprofessional primary health care (PHC) team and her care was coordinated by a family physician in August 2024. Hyperbasalization was identified, with a ratio of 8.2 IU of basal insulin to 1 IU of rapid-acting insulin, with an HbA1c of 13.6% (July 2024).

Originality: This case report exemplifies how therapeutic inertia, sporadic uniprofessional care, hyperbasalization, and inappropriate use of antidiabetic drugs can lead to adverse outcomes.

Lessons learned and future implications: Over 14 months, 12 medical consultations were conducted, five with a nutritionist, three with a pharmacist, and two with a nurse. The ratio was adjusted to 1.25 IU of basal insulin for every 1 IU of rapid-acting insulin, with a final dose of 1.8 IU/kg/day of insulin. Dapagliflozin 10 mg once-daily was introduced. Finally, in September 2025, HbA1c reached 7.0% without episodes of hypoglycemia.

Discussion: The perception of hyperbasalization without achieving glycemic control and the intensification of interprofessional care concomitant with the optimization of pharmacotherapy enabled glycemic stabilization, with HbA1c at the therapeutic target, delaying the progression of macro and microvascular complications.

Conclusion: This real clinical case demonstrates that even in complex situations, with clinical fragility and vulnerability, intensive and interprofessional care is capable of promoting glycemic control and improving quality of life.

Context: Pulmonary disease caused by Mycobacterium avium complex (MAC) represents an increasing complication in patients with bronchiectasis. Its diagnosis requires clinical, radiological, and microbiological integration, posing a challenge for Primary Care (PC) in differentiating between colonization and active infection.

Methods: A 74-year-old man, non-smoker, with a 25-year history of thoracic trauma resulting in residual bronchiectasis. In 2017, he had pneumonia with MAC isolated in bronchoalveolar lavage (BAL), considered sample contamination and left untreated. Since then, he remained asymptomatic except for a 20-kg weight loss, maintaining an active lifestyle without cough or dyspnea. He presented with isolated hemoptoic sputum preceded by fever, causing concern for himself and family. Physical exam, blood tests and chest radiograph in PC were normal. Given the history and symptoms, after empirical levofloxacin, he was referred to Pulmonology for a full radiological study. Chest CT scan showed cylindrical bronchiectasis in the lingula and middle lobe, with multilobar centrilobular nodules, some cavitary, and peribronchovascular and subpleural consolidations bilaterally. A low-attenuation mass (35x20 mm) was noted in the right lower lobe. Bronchoscopy with culture confirmed Haemophilus parainfluenzae and repeated isolation of MAC with positive auramine staining, ruling out tuberculosis and resistant mutations. The diagnosis of pulmonary MAC disease was confirmed, dismissing the prior contamination assumption. He began a thrice-weekly regimen of azithromycin, ethambutol, and rifampicin. Under PC follow-up with close Pulmonology coordination, he continues to be

monitored for clinical evolution and drug tolerance.

Originality: This case is notable for absence of classic risk factors, post-traumatic bronchiectasis, and early diagnostic uncertainty.

Lessons learned and future implications: Longitudinal assessment in PC is vital to detect clinical and radiological progression. Continuous education and close collaboration with other specialists optimize outcomes in complex cases.

Discussion: Pulmonary MAC disease in the context of bronchiectasis poses a diagnostic challenge for primary care due to difficulty in differentiating colonization from active infection. This case illustrates how close collaboration with Pulmonology and integration of clinical, radiological, and microbiological data are essential for proper diagnosis and management.

Conclusion: Ongoing evaluation and interdisciplinary collaboration fortify PC's role in managing pulmonary MAC disease, emphasizing patient-centered care and shared decision-making for improved outcomes.

ID 1757- Health support challenges among type 2 diabetes patients amid community general practice service gaps in chaoyang district, beijing: a qualitative study using the andersen's behavioral model

Sila ALTUNTAS, Onur EMRE, Ilgin IMIR, Vildan MEVSIM, Buse HAZINEDAROĞLU

Dokuz Eylül University, Faculty Of Medicine, Department Of Family Medicine, İzmir, Türkiye

Context: Extremely restrictive diets among young adults—often influenced by social media—can cause acute metabolic instability. Symptoms may appear nonspecific, and individuals may attend routine visits rather than present with clear complaints. In primary care, detailed nutritional history is essential to identify high-risk dietary patterns and prevent serious outcomes. Lifestyle-focused assessment helps contextualize subtle presentations and supports early intervention.

Methods: A 23-year-old woman visited a family health center for routine weight monitoring and laboratory evaluation. She reported following a "water diet" for one month, consuming 1–1.5 liters of water and occasional low-calorie liquids, with nearly no solid food. She experienced rapid weight loss (7–9 kg/month), palpitations, fatigue, cold extremities, and menstrual delay. Shortly after leaving the examination room, she developed sudden dizziness and brief loss of consciousness. Reassessment showed hypotension (85/55 mmHg), tachycardia (112 bpm), reduced skin turgor, and capillary glucose of 59 mg/dL. She improved quickly with positioning and oral glucose. Suspecting metabolic disturbance, she was urgently referred for testing. Laboratory results revealed mild hypoglycemia, electrolyte imbalance, ketonuria consistent with starvation ketosis, mild metabolic acidosis, and low ferritin with mild anemia. At follow-up, the metabolic consequences of extreme caloric restriction were explained. Motivational interviewing addressed her weight-loss motives and psychosocial influences. A gradual caloric restoration plan, hydration guidance, healthy plate education, and counseling on safe weight management were provided.

Originality: Although restrictive dieting is common, this case demonstrates syncope directly linked to a social-media-driven diet trend, emphasizing the ability of primary care to identify metabolic crises through lifestyle-focused assessment.

Lessons learned and future implications: Young adults may adopt extreme diets without recognizing risks. Early lifestyle-oriented questioning can prevent severe metabolic consequences and reduce emergency visits. Structured nutrition screening in routine assessments may help counter unsafe diet trends.

Discussion: The patient's syncope was explained by caloric deprivation, ketosis, and hypoglycemia. Evidence supports motivational

interviewing and gradual caloric reintroduction as effective first-line strategies.

Conclusion: Extreme dieting can cause acute metabolic instability and syncope. Comprehensive nutritional assessment and patient-centered counseling in primary care enable timely recognition and safer recovery. MeSH:Syncope, Starvation, Metabolic Disorders, Nutrition Assessments

Context: Cardiovascular diseases are one of the main causes of mortality and morbidity worldwide. The effectiveness of Cardiac Rehabilitation programmes (CRP) after acute coronary syndrome (ACS) has been previously stablished, however the effectiveness of CRP in Primary Healthcare (PHC) has not been clearly evaluated from a population-based analysis.

Objectives: To assess cardiovascular risk factor (CVRF) control, lifestyle modifications, comorbidities and follow-up of patients after ACS in a healthcare area where a new CRP including PHC has been implemented.

Methods: For the purposes of this study, we included all individuals with a new ICD-10-CM code for ACS in 2021 and in 2024 in our healthcare area. To evaluate the association of the new CRP with outcomes we compared results from 2021 (pre-implementation) with 2024 (post-implementation. We performed a multivariate adjusted Cox proportional hazard model.

Results: A total of 256 patients were included in the study (166 in 2021 and 193 in 2024). We are still in the process of data analysis but with some good preliminary data we aim to be able to have really interesting population-based results.

Discussion: Unable to do until finishing the evaluation.

Conclusion: PHC has a key role in CRP in patients after ACS, there is a need of population-based studies to assess effectiveness of them including all profiles of patients.

ID 672- Hemorrhagic stroke in a primary care setting: a case report

Leyla ASLANKAYA, Ozan Emre ELIACIK, Vildan MEVSIM

Dokuz Eylül University Faculty Of Medicine, Department Of Family Medicine, Izmir, Türkiye

Context: Behçet's disease (BD) is a chronic, relapsing multisystem vasculitis often presenting with mild, nonspecific symptoms. Early manifestations may appear across multiple visits, making primary care essential in recognizing multisystem patterns. Early identification and referral can prevent severe complications like ocular, neurologic, gastrointestinal, and vascular involvement.

Methods: A 31-year-old woman presented with recurrent painful oral aphthous ulcers. Her history included genital ulcers, erythematous leg lesions (suggestive of erythema nodosum), and unintentional weight loss (10 kg in 6 months). Rheumatologic review revealed photosensitivity, episodic pain in joints, and transient MCP arthritis. She also had a single episode of hematochezia two months prior. Denying fever, uveitis, and other specific symptoms, physical examination revealed active oral ulcers and MCP tenderness. Lab tests showed negative ANA, ENA, RF, and anti-CCP, but elevated CRP and ESR. Ophthalmologic evaluation showed no ocular involvement.

Gastroenterology scheduled a colonoscopy to assess hematochezia. Based on recurrent mucosal ulcers, vasculitic skin lesions, and episodic arthritis, BD was likely, and the patient was referred for further management.

Originality: The diagnosis was made not from a single symptom but through the integration of fragmented symptoms across multiple systems. This case illustrates how routine complaints like oral ulcers can reveal underlying multisystem vasculitis when assessed comprehensively.

Lessons learned and future implications: BD often presents in a fragmented manner, making early symptoms easily overlooked. Primary care clinicians should maintain suspicion when oral ulcers coexist with genital ulcers, erythema nodosum, peripheral arthritis, or gastrointestinal symptoms. Comprehensive history-taking and careful examination can reduce delays in diagnosis and long-term morbidity.

Discussion: BD is often underdiagnosed due to its variable presentation. Early recognition through primary care continuity and broad differential thinking allows for timely referral and treatment, minimizing the risk of complications such as vision loss, vascular issues, and chronic gastrointestinal disease.

Conclusion: This case emphasizes the crucial role of family physicians in recognizing early multisystem involvement and facilitating timely referral and multidisciplinary management, preventing diagnostic delay.

ID 1293- Hernia umbilical incarcerada diagnosticada en Atención Primaria

Onur EMRE, Sıla ALTUNTAS, Ilgın IMIR, Vildan MEVSIM

Dokuz Eylul University, Faculty Of Medicine, Department Of Family Medicine, Izmir, Türkiye

Context: Acute coronary syndrome(ACS) classically manifests with chest pain; however, up to one-third of patients present with atypical symptoms such as isolated back pain, nausea, fatigue, or diaphoresis. These presentations pose a significant diagnostic challenge in primary care, where rapid identification and referral are critical to prevent morbidity and mortality. This case illustrates how clinical vigilance, combined with the use of a national digital risk-stratification tool, enabled timely recognition of ACS despite the absence of chest pain.

Methods: A48-year-old man with family health center with six hours of persistent upper back pain, nausea, and mild diaphoresis, but without chest discomfort.. Physical examination was unremarkable, and musculoskeletal palpation did not reproduce symptoms. Although the presentation appeared non-cardiac at first glance, the family physician evaluated cardiovascular risk using Türkiye's national digital decision-support system. Based on the patient's age, smoking status, dyslipidemia, and symptoms,HYP indicated a moderate-to-high 10-year cardiovascular risk and recommended ECG despite the atypical presentation. An in-clinic ECG showed non-specific ST-T abnormalities. Hospital evaluation demonstrated elevated troponin I levels, confirming NSTEMI.

Originality: This case emphasizes that ACS may present without chest pain and that digital decision-support platforms can play a pivotal role in guiding diagnostic decisions in real time. The integration of HYP into routine assessment prevented potential diagnostic delay by alerting the clinician to cardiovascular risk despite nonclassical symptoms.

Lessons learned and future implications: Atypical symptoms alone should not rule out ACS, especially in individuals with cardiovascular risk factors. Combining clinical judgment with validated digital tools enhances risk stratification and supports timely referral. Wider integration of decision-support systems into primary care may reduce missed ACS diagnoses and improve outcomes.

Discussion: Literature indicates that atypical ACS presentations are associated with delayed care and worse prognosis. This case demonstrates that primary care clinicians must consider ACS in patients with unexplained upper back pain and risk factors.Digital platforms may augment clinical vigilance by

triggering cardiac evaluation before overt myocardial injury occurs.

Conclusion: ACS can present atypically, and reliance on classical chest pain may lead to missed or delayed diagnosis. Continuous symptom vigilance, awareness of risk factors, and technology-assisted clinical decision-making can support accurate evaluation and prompt referral, strengthening primary care management of ACS.

Context: How to teach general practitioners point-of-care ultrasound (POCUS) and what scanning modalities to include in a curriculum have been a subject of on-going discussion. Recently new guidelines on how to teach POCUS in general practices has been published by the European Federation of Ultrasound in Medicine and Biology (EFSUMB). The newly formed European Family Medicine Ultrasound Society (EFMUS) will host this workshop to present the main conclusions of these guidelines. What are the barriers for implementing them and how can they be overcome? A live POCUS demonstration will show if the recommendations are relevant for you in your daily work.

Objectives: The aim of the workshop is: 1. To present EFSUMB´s newly published guidelines on POCUS curriculum development and training. 2. To demonstrate the five most popular scanning modalities across Europe and their clinical implications. 3. To discuss curriculum development and implementation of training guidelines across Europe.

Teaching method and workshop: The workshop will start with a brief presentation of the newly published EFSUMB recommendations regarding training and curriculum development. Afterwards a live POCUS demonstration of 5 scanning modalities will be performed together with patient cases ill

Expected outcomes: After the workshop, participants will know about the evidence-based recommendations for POCUS training published by the EFSUMB taskforce. Participants will have reflected on the status of POCUS training in their respective countries and discussed to how t

Conclusion: The workshop aims to raise awareness evidence-based approaches to POCUS education in general practice and serve as an inspiration on how to implement training in their respective countries.

ID 1397- Home care services in Turkey: An interactive workshop on autonomy, equity and human-centered primary care

Sila ALTUNTAS, Ilgin IMIR, Onur EMRE, Vildan MEVSIM, Buse HAZINEDAROĞLU

Dokuz Eylül University, Faculty Of Medicine, Department Of Family Medicine, İzmir, Türkiye

Context: Accurate and complete medical history-taking is essential for safe primary care assessment. When patients intentionally or unintentionally omit key medical information—especially concerning chronic or neurological disease—clinical reasoning, risk assessment, and emergency management become significantly more challenging. During acute neurological events, rapid access to reliable history is critical; missing information can delay appropriate intervention and compromise patient safety.

Methods: A 36-year-old man presented to a family health center with sore throat and malaise consistent with an upper respiratory tract infection. He clearly denied any chronic illness or neurological history. Vital signs and physical examination were stable, and he was discharged with symptomatic treatment. Minutes after leaving, he collapsed outside the clinic, developing sudden altered consciousness followed by a generalized tonic–clonic seizure. He was brought back inside, where airway support and seizure first aid were provided. Emergency medical services were activated for urgent transfer. After the event, collateral history obtained from family revealed a previously diagnosed neurodegenerative disorder that the patient had intentionally concealed. Review of national electronic medical records confirmed long-standing neurological disease followed in tertiary care.

Originality: Although incomplete history is common, this case is notable due to deliberate concealment of a rare neurological condition, which directly contributed to delayed recognition of risk. It demonstrates diagnostic vulnerability in primary care when decisions rely solely on patient-reported history.

Lessons learned and future implications: When the clinical picture does not align with a patient's stated history, clinicians should promptly seek collateral information. Rapid access to prior electronic records or family input may improve safety during atypical or high-risk presentations. Strengthening trust and explaining the importance of accurate disclosure may reduce future concealment.

Discussion: The unexpected seizure highlighted the limitations of relying exclusively on self-reported medical history. Literature shows concealed illness contributes to diagnostic delays and preventable complications. Early collateral verification may reduce morbidity in acute presentations.

Conclusion: Undisclosed medical history can impair diagnostic accuracy and emergency response in primary care. When inconsistencies arise, collateral confirmation should not be delayed. Trust-based communication and complete disclosure remain essential for safe, effective primary care. MeSH:

Neurodegenerative Diseases, Medical History Taking, Seizures, Patient Disclosure

Corresponding author: Sila Altuntas, silaltuntas@outlook.com

ID 1059- Home Monitoring in Primary Care for CVRM Patients

Maria GAMENHAS, Ricardo MARQUES, Sofia NEVES, Teresa ANTUNES, André NEGRÃO

Usf Ribeirinha, Barreiro, Portugal

Context: A 52-year-old woman with early-onset dementia experiencing a significant impact on her work and social life. The underlying pathology presents with an inability to manage finances, schedule appointments, cook, time and space disorientation, and aphrasia. The only family support she has is her 86-year-old father, who does not understand his daughter's condition.

Methods: Without family support, and without a way to communicate with the patient (she has no phone or email), getting her to attend appointments, have exames done, or take her medication was a Herculean task. The case was presented to the health center team, and several possibilities were proposed: sending her to the Neurologic emergency service, contacting the Social Worker, scheduling a home visit. It was agreed with the team that whenever the patient comes to the health center, the family doctor should be contacted to examine her (the patient never shows up on the day of her appointment because she forgets the scheduling).

Originality: The family doctor opted to establish a network of social support: scheduled a home visit with the social worker, a certificate of incapacity for work was issued and directly delivered by the doctor to the employer, a medical board for verification of incapacity at home was requested, the patient was assisted in filling out the incapacity certificate, the Health Delegate was contacted to expedite the process of applying for an invalidity pension (to be done at home), and long-term support was proposed such as: home support, assisted adult status or institutionalization.

Lessons learned and future implications: More pre and post-graduated training in social support would have facilitated the management of this patient and should be a point of reflection for the training of today's doctors, knowing that we will have increasingly more dependents (mostly elderly) in our society.

Discussion: The doctor is the patient's advocate, only seeking their well-being and health.

Conclusion: The family doctor's role goes further, involving establishing a support network, guiding the patient, showing him alternatives, working together with the social worker, other specialties and the employer, with a single purpose – the patient's well-being.

ID 1000- Home-based interventions in patients with cardiometabolic diseases or with risk factors for the development of cardiometabolic diseases: A scoping review

Onur EMRE, Sıla ALTUNTAS, Ilgın IMIR, Vildan MEVSIM

Dokuz Eylul University, Faculty Of Medicine, Department Of Family Medicine, Izmir, Türkiye

Context: Aortic dissection is a life-threatening cardiovascular emergency. frequently attributed to benign causes such as musculoskeletal strain. This can delay life-saving diagnosis, particularly in primary care, where patients often first present with nonspecific back or chest pain. Early recognition of red-flag features and rapid referral are therefore essential.

Methods: A 26-year-old male presented to a family medicine clinic with sudden, severe upper back pain described as “tearing” between the scapulae. Although musculoskeletal pain was initially considered due to localization, vital signs and examination findings raised concern: BP 160/92 mmHg, HR 112 bpm, weaker left-arm pulse, >20 mmHg inter-arm blood pressure difference. These findings, combined with the abrupt onset and

pain characteristics, shifted diagnostic suspicion toward an aortic emergency. emergency referral with high suspicion for acute aortic dissection was initiated. CT angiography performed at the hospital confirmed Stanford Type A aortic dissection.

Originality: Although acute aortic dissection is well documented in older adults, primary care identification in a patient under 30 is exceptional. This case demonstrates how subtle but critical clinical clues—sudden tearing back pain, inter-arm blood pressure discrepancy, pulse asymmetry, diastolic murmur, family history of early cardiac death, and past aortic findings—can drive correct suspicion even when age falsely suggests low risk.

Lessons learned and future implications: Young age does not exclude life-threatening aortic pathology. Acomprehensive cardiovascular history, including family history and previous imaging abnormalities, should be obtained in patients with acute back pain. Recognizing red-flag findings enables primary care physicians to expedite emergency referral and prevent catastrophic outcomes. Medical education should reinforce awareness of atypical aortic dissection presentations inyounger populations.

Discussion: Literature shows that missed or delayed diagnosis of aortic dissection is strongly associated with increased mortality. Primary care clinicians must prioritize early recognition of tearing pain and inter-arm BP differenceseven without chest pain—to avoid fatal outcomes. This case supports integrating structured cardiovascular risk screening into back pain evaluations when red flags are present.

Conclusion: Acute aortic dissection must be consideredin sudden, severe back pain regardless of age. Prompt recognition of red-flag symptoms and urgent referral can be lifesaving. Primary care playsa pivotal role in early detection, especially when atypical presentations could easily be mistaken for benign musculoskeletal pain.

ID 2042- Home-based point of care ultrasound performed by nurses in a home care team: a practice-based experience

Onur EMRE, Sıla ALTUNTAS, Ilgın IMIR, Vildan MEVSIM

Dokuz Eylul University, Faculty Of Medicine, Department Of Family Medicine, Izmir, Türkiye

Context: Chronic insomnia is a frequent presentation in primary care and often results in referrals to psychiatry or neurology. However, behavioral and environmental determinants—specifically sleep hygiene disturbances—are highly prevalent yet commonly underrecognized. Early detection of sleep hygiene problems can prevent unnecessary pharmacologic treatment and reduce the need for specialist referrals.

Methods: A 38-year-old man presented with persistent insomnia and daytime fatigue despite previous neurological and psychiatric evaluations and two unsuccessful medication trials. A structured sleep history explored bedtime routines, wake time variability, screen exposure, caffeine intake, stress, and environmental conditions. A sleep diary demonstrated irregular sleep–wake cycles, smartphone use shortly before bedtime, caffeine intake after 17:00, cognitive hyperarousal related to work stress, and a bright, noisy bedroom environment.

Originality: This case demonstrates chronic insomnia driven primarily by modifiable sleep hygiene disturbance, underscoring the diagnostic and therapeutic value of primary care in identifying behavioral determinants before initiating sedative–hypnotic medication or referring to specialist services.

Lessons learned and future implications: Sleep hygiene disturbance is a common and modifiable cause of chronic insomnia. Comprehensive lifestyle and environmental assessment in primary care can reduce unnecessary specialist referrals and medication use. Behavioral management—including patient education, sleep diaries, and stress-reduction strategies—can yield significant improvement.

Discussion: The findings of this case demonstrate that sleep hygiene disorder can be a sufficient underlying mechanism for chronic insomnia, echoing international evidence. Guidelines from the American Academy of Sleep Medicine and the European Sleep Research Society recommend behavioral and sleep hygiene interventions as first-line therapy, often matching or surpassing pharmacologic treatment in long-term outcomes. Studies consistently identify irregular sleep–wake schedules, evening screen exposure, late caffeine intake, and cognitive hyperarousal as prevalent contributors. The present case reflects a common pattern described in the literature: prior specialist evaluations and medication trials occurred before lifestyle factors were explored. Successful symptom resolution through a holistic primary care strategy reinforces the need to incorporate detailed behavioral and environmental sleep assessment into routine insomnia management.

Conclusion: A holistic approach in primary care that prioritizes sleep hygiene, lifestyle modification, and environmental optimization can significantly improve chronic insomnia. Early recognition and patient-centered education empower individuals to manage symptoms effectively and minimize reliance on medication-based approaches.

ID 1170- Honey-Based Dressings as a Practical, Evidence-Informed, and Cost-Effective Approach to Wound Care in Primary Care

Melike ALSANCAK [(1)] , Altuğ KUT [(2)]

(1) Etimesgut District Health Directorate, Ankara, Türkiye
(2) Başkent University Hospital, Ankara, Türkiye

Context: Pruritus is frequently encountered in primary care and is often attributed to benign dermatologic or allergic conditions. Aquagenic pruritus (AP), however, is a recognized early manifestation of polycythemia vera (PV). Awareness of AP is important because timely interpretation of subtle symptoms and routine laboratory abnormalities can enable rapid referral and help prevent thrombotic complications.

Methods: A 46-year-old woman presented with a six-month history of intense itching after hot showers, accompanied by tingling in the left hand. Previous antihistamine and topical steroid treatments had not been effective. Physical examination was unremarkable. Initial evaluation revealed hemoglobin 17.3 g/dL, hematocrit 52.4%, platelets 442×10^9/L. She was referred to the hematology department for further evaluation. Bone marrow biopsy confirmed hypercellularity with increased megakaryocytes and a normal myeloid-to-erythroid ratio. Further testing showed JAK2 V617F positivity. These findings supported a myeloproliferative neoplasm. Although the initial presentation could suggest dermatologic, neurologic, or allergic conditions these possibilities were reconsidered in light of the markedly abnormal hematologic findings. The combination of AP, elevated hemoglobin/hematocrit, thrombocytosis, low EPO, and JAK2 positivity made alternative diagnoses less likely. She received aspirin and consecutive phlebotomies, with improvement in pruritus and paresthesia.

Originality: Large cohort studies report that AP affects most patients and often begins several years before diagnosis; however, only about 15% of patients undergo hematologic evaluation during this period, contributing to diagnostic delay. This highlights the valuable contribution of primary care to the timely identification of polycythemia vera, particularly in younger patients, where the diagnosis is less expected. PV most commonly presents around age 60, and this case represents a younger presentation than described in the literature.

Lessons learned and future implications: Persistent aquagenic pruritus is a finding that should prompt consideration in primary care settings. Recognizing accompanying abnormalities can help reduce diagnostic delays and improve outcomes.

Discussion: This case demonstrates how integrating nonspecific symptoms with routine laboratory findings can support clinical reasoning in primary care.

Conclusion: This case shows that nonspecific symptoms like pruritus, when interpreted in conjunction with complete blood count findings, provide diagnostic clues and support the earlier identification of conditions like polycythemia vera in primary care.

Context: Civilian spaceflight is expanding, creating new clinical and legal responsibilities for general practitioners (GPs). Pre-flight medical clearance involves high-risk certification, disclosure duties, and potential liability if relevant conditions are missed. Post-flight symptoms may trigger insurance disputes over causation, non-disclosure, or operator responsibility. This workshop uses a staged clinical vignette to examine screening, diagnosis, documentation, and medico-legal accountability in recreational spaceflight.

Objectives: Participants will be able to: Describe legal and procedural requirements for medical clearance for spaceflight. Identify high-risk pre-existing conditions relevant to liability. Recognise common post-spaceflight clinical presentations. Analyse medico-legal dilemmas involving patient disclosure, operator duties, and clinician responsibility.

Teaching method and workshop: Teaching methods A progressive-disclosure vignette guides small-group analysis. Each phase adds new clinical or legal information, prompting reinterpretation of risk and responsibility. Methods include case discussion, legal decision-tree mapping, insurer

Expected outcomes: Participants will strengthen their ability to conduct legally sound fitness assessments, recognise post-spaceflight symptoms, and document encounters to withstand insurance and legal scrutiny. Skills are transferable to other emerging high-risk activities

Conclusion: As space tourism evolves, primary care clinicians must integrate medical judgement with legal accountability. Through a structured vignette, this workshop equips GPs to navigate certification, diagnosis, and medico-legal responsibility within this new aerospace-health landscape.

(2) Dokuz Eylul University, Faculty of Medicine, Department of Family Medicine, İzmir, Türkiye

Context: Chronic abdominal pain and diarrhea are common in primary care and often investigated extensively. When tests are normal, symptoms may arise from modifiable lifestyle, dietary, or environmental factors. A holistic assessment of daily habits, food environments, and work routines can reveal overlooked triggers.

Methods: A 24-year-old woman presented with several months of intermittent abdominal pain and diarrhea. Previous evaluations, including upper endoscopy and colonoscopy, were normal. A comprehensive assessment explored symptom timing, diet, food sources, work environment, stress, sleep, bowel habits, and psychosocial factors. The patient reported being symptom-free on weekends when eating home-cooked meals but experiencing flares during workdays. She frequently consumed high-fat, fried cafeteria meals due to limited time at work. Stress and sleep patterns were unrelated to symptoms. Pain and diarrhea typically began two to four hours after cafeteria

meals. A personalized lifestyle plan was created recommending avoidance of high-fat workplace foods and encouraging healthier pre-prepared meals. No medication was prescribed.

Originality: This case illustrates that persistent gastrointestinal symptoms with normal test results may reflect everyday dietary exposures. The clear link between cafeteria meals and symptom flares represents a situational trigger unlikely to be recognized without structured lifestyle questioning.

Lessons learned and future implications: Chronic gastrointestinal symptoms should prompt clinicians to explore diet and environmental contributors rather than rely solely on biomedical testing. Routine incorporation of lifestyle assessments—including eating patterns, food environments, and work routines—can identify modifiable triggers. Integrating lifestyle counseling into primary care may reduce unnecessary investigations and improve patient outcomes.

Discussion: Diagnostic testing rules out organic disease but cannot capture environmental influences. In this case, symptoms were diet-specific and setting-dependent. Targeted lifestyle modification achieved meaningful improvement. Evidence shows functional abdominal pain and diarrhea often improve with dietary changes, particularly reducing high-fat meals.

Conclusion: Holistic assessment is essential in managing chronic gastrointestinal symptoms. Evaluating lifestyle, diet, and environmental factors alongside medical tests enables early identification of modifiable triggers. Personalized lifestyle change can significantly improve outcomes even when diagnostic findings are normal. MeSH: Abdominal Pain, Diarrhea, Environment

Odilon Quentin ASSAN [(1)], Claude Bernard UWIZEYE [(1)], Roberta DE CARVALHO CORÔA [(2)], France LÉGARÉ [(1)]

(1) Canada Research Chair In Shared Decision Making And Knowledge Mobilization, Quebec City, Ca; Unité De Soutien Au Système De Santé Apprenant Québec, Quebec City, Ca; Vitam – Centre De Recherche En Santé Durable, Quebec City, Ca, Quebec, Canada
(2) Université Laval, Quebec City, Ca, Quebec, Canada

Context: Healthcare systems must be learning-oriented, resilient, efficient, and collaborative. In this context, shared decision-making (SDM) is a cornerstone for relevant, equitable, sustainable care. SDM fosters balanced dialogue between patients and professionals, ensuring informed choices aligned with patients' values. Despite proven benefits for outcomes, experience, team well-being, and equity, its implementation remains uneven. This workshop offers a space to share practical strategies and tools including decision aids to make SDM actionable.

Objectives: By the end of this workshop, participants will be able to: 1. Explain the context in which shared decision-making (SDM) is situated in 2024. 2. Describe the process and key steps of coconstructing decision aids for population-based screening programs. 3. Present some of these codeveloped decision aids. 4. Apply them in potential scenarios.

Teaching method and workshop: Teaching methods Interactive strategies, including expectation mapping, small-group discussions, table-based reflections, and plenary exchanges: Participants will engage in practical exercises and collaborative analysis to reinforce learning. Workshop sch

Expected outcomes: This workshop will introduce or strengthen participants' knowledge, ability and toolkit to apply decision aids for more informed, equitable, humanist and liberate care decisions in the context of population-based screening.

Conclusion: Through this workshop, we aim to strengthen participants' ability and toolkit to

apply SDM and decision aids effectively in their practice for population-based screening. Participants will leave with actionable strategies and resources to promote informed, value-based care decisions.

Context: Gender inequality in biomedical research and clinical trials limits understanding of women's health, leading to diagnostic delays and inadequate treatment. Addressing these gaps is crucial for improving care and health outcomes for women.

Objectives: Participants in the workshop will learn to recognize gaps in women's representation in research and understand how these deficiencies impact both diagnosis and treatment. In addition, they will identify common forms of gender bias that occur in clinical practice and consider their effects on patient care. Attendees will also apply gender-sensitive, evidence-informed approaches to the assessment, management, and communication with women patients, fostering more equitable and effective healthcare delivery.

Teaching method and workshop: The workshop will employ an interactive format featuring real-life clinical scenarios to engage participants actively. It will incorporate the latest scientific data on gender disparities, enabling attendees to ground their learning in current evidence. G

Expected outcomes: Participants in the workshop will demonstrate increased awareness of how gender inequality influences clinical presentations, diagnostic accuracy, and treatment outcomes for women. They will integrate gender-sensitive approaches into routine assessment, h

Conclusion: This workshop equips GPs with evidence-based, gender-sensitive tools to address inequality in women's health. By engaging with real cases and scientific data, participants learn to recognize bias and improve care outcomes for women.

Context: Globally, interest in equity and humanism in healthcare is growing. Scaling innovations through systematic, evidence-based processes is key to achieving this goal. Scaling means increasing the impact of proven innovations by disseminating, replicating, or adapting them across contexts—a process that involves multiple steps. One critical step is scalability assessment, which determines whether innovations can achieve impact at scale. This step helps identify strengths, gaps, and contextual factors that influence success before scaling. In this workshop, we will present and apply the Innovation Scalability Self-administered Questionnaire (ISSaQ 4.0), a tool designed to assess scalability.

Objectives: By the end of this workshop, participants will be able to: 1. Define scalability assessment and explain its role in achieving greater equity and humanism in primary

healthcare within the scaling process. 2. Apply the Innovation Scalability Self-administered Questionnaire (ISSaQ 4.0) to evaluate the scalability of an innovation.

Teaching method and workshop: Teaching methods Interactive strategies, including expectation mapping, small-group discussions, table-based reflections, and plenary exchanges: Participants will engage in practical exercises and collaborative analysis to reinforce learning. Workshop sch

Expected outcomes: At the end of this workshop, participants will understand why scalability assessment is a critical step for achieving equity and humanism in primary healthcare. They will gain practical experience using ISSaQ 4.0 and learn how scalability assessment resul

Conclusion: Scalability assessment helps innovations in primary healthcare achieve equitable, humanistic impact by confirming they are suitable for diverse contexts and populations. ISSaQ 4.0 offers a structured approach to guide decisions, foster collaboration, and align scaling with equity and humanism.

Marika SULASHVILI [(1)], Nodar SULASHVILI [(2)]

(1) The University Of Georgia, Tbilisi, Géorgie
(2) Tbilisi State Medical University, Tbilisi, Géorgie

Context: Anxiety disorders (ADs) are highly prevalent, heterogeneous group of psychiatric conditions with an impressive public health impact. Twin and family studies confirm a moderate heritability (typically 30-50%), suggesting a clear genetic predisposition. However, the complexity and polygenic nature of ADs, where many common genetic variants each contribute only a small effect, have meant that Genome-Wide Association Studies (GWAS) have had limited success in identifying major causative loci. This gap underscores the critical role of environmental factors and their interaction with the genome in disease pathogenesis. Epigenetics provides the critical mechanism for this gene-environment interaction. These reversible modifications, which include DNA methylation, histone modifications, and non-coding RNAs (ncRNAs), alter gene expression without changing the underlying DNA sequence. The majority of environmental stressors, particularly early-life adversity, can lead to persistent epigenetic changes, biologically embedding vulnerability and altering an individual's response to stress later in life.

Objectives: The aim of our study was to investigate the role of genetic polymorphisms, genetic variants and epigenetic modifications in anxiety disorders

Methods: We have done literature review and summarised the data

Results: Research, mainly utilizing animal models, has identified epigenetic modifications in brain regions critical for stress and emotion regulation, such as the amygdala, hippocampus, and prefrontal cortex (PFC). These modifications often target genes involved in the Hypothalamic-Pituitary-Adrenal (HPA) axis (e.g., NR3C1, FKBP5) and neurotransmitter systems (e.g., GABAergic and serotonergic pathways). For instance, altered DNA methylation of the NR3C1 gene, which encodes the glucocorticoid receptor, has been implicated in an abnormal stress response.

Discussion: DNA methylation is a crucial epigenetic mechanism that plays a significant role in the pathophysiology of anxiety disorders by influencing gene expression in brain regions associated with stress and emotion.

Conclusion: In conclusion, the current understanding of Anxiety disordres demonstraits a complex interplay between an individual’s genetic predisposition and epigenetic alterations induced by environmental exposure. Future research integrating large-scale genetic and epigenetic data across diverse populations is essential to fully characterize the risk architecture of ADs. This neuroepigenetic perspective offers promising avenues for identifying novel biomarkers for risk prediction and developing targeted, epigenetic-based therapeutics to

modulate maladaptive gene expression patterns.

Yanica VELLA

Primary Health Care Malta, Gzira, Malte

Context: Early manifestations of lymphoproliferative disorders can be subtle and easily overlooked. Cough and pruritus frequently mimic benign dermatological or respiratory conditions.

Methods: 36 year old lady presenting to the clinic with a 6 week history of worsening cough, white phlegm, no systemic symptoms. Smokes 25 cigartettes daily. Normally fit and well. She was on anxiolytics which were prescibed for pruritus one year ago. She had multiple presentations with generalized pruritus for which she was prescribed emolients, antihistamines and anxiolytics as this was attributed to her anxiety. But this did not settle. When asked about her anxiety she did not seem concerned. Examination revealed multiple scratch marks . She had a CXR in view of the duration of her cough. Showed bilateral hilar lymphadenopathy and right sided pleural effusion. Blood tests showed elevated white cells. She was discussed with respiratory team, had a CT Thorax which showed extensive lymphadenopathy suggestive of lymphoproliferative disease and biopsy of lymph node suggesting Lymphoma. She was started on chemotherpay and is stable.

Originality: This case presented with unusal presentation of Lymphoma, cough and generalized pruritus without obvious lymphadenopathy. These symptoms are normally attributed to allergies or viruses making the case diagnostically challenging. Lymphomas present with B symptoms but pruritus alone without fever, night sweats or weight loss can be misleading. This case highlights how easily malignancies can be masked by everyday symptoms.

Lessons learned and future implications: Symptoms that do not resolve with initial management warrant re-evaluation. The patient had multiple presentations with pruritus and given treatments which were not working. Her cough was present on most days but was not given importance. Importance of recognizing non-specific but persistent symptoms and considering a broader differential diagnosis, including less common ones like lymphoma.

Discussion: In cases with persistent pruritus and cough CBC, CRP & CXR should be considered. Missing early opportunitues for investigation can contribute to delayed diagnosis.

Conclusion: This is a strong example of how common presentations can hide serious disease and importance of educating others for diagnostic curiosity. Brings to light ways of potentially imroving practice by implementing quality improvement initiatives around, persistent symptoms, red flags check list, documentation and follow up protocols.

Gabriele GOGELYTE [(1)], Kazys SIMANAUSKAS [(2)]

(1) Vilnius University, Faculty Of Medicine, Vilnius, Lituanie
(2) Vilnius University, Faculty Of Medicine, Institute Of Clinical Medicine, Clinic Of Internal Diseases And Family Medicine, Vilnius, Lituanie

Context: Awareness of iron deficiency and its early manifestations has grown in recent years. Although oral iron remains first-line therapy, many patients fail to tolerate or adequately respond to it, leading to broader use of intravenous iron isomaltoside in primary care settings. While IV iron is generally safe, both pseudoallergic and true allergic hypersensitivity reactions can occur. Early recognition and timely management are critical to ensuring patient safety.

Methods: Clinical data for this case report were obtained from a 29-year-old otherwise healthy woman who developed a hypersensitivity reaction during an intravenous iron isomaltoside infusion. Data were collected through direct observation and continuous monitoring of vital signs during the infusion and for 1.5 hours thereafter. Additional information was retrieved from electronic medical records and from a follow-up assessment after treatment. The infusion protocol, onset and progression of symptoms, and all therapeutic interventions—including administration of corticosteroids and antihistamines—were documented in chronological order. Written informed consent for infusion and publication was obtained from the patient.

Originality: The case presents real-time management of hypersensitivity reactions to iron isomaltoside infusion.

Lessons learned and future implications: Hypersensitivity reactions to intravenous iron can occur even in young patients without prior allergy history. Immediate recognition, stepwise management, and close monitoring are essential for preventing complications.

Discussion: Pseudoallergic hypersensitivity reactions to intravenous iron may present with subtle early symptoms such as head heaviness or mild pruritus before progressing to more pronounced manifestations. In this case, a rapid escalation from mild to objective symptoms (urticaria) underscores the importance of early recognition. The lack of response to dexamethasone alone and immediate improvement after clemastine supports existing guidance that antihistamines are central in the management of pseudoallergic IV iron reactions, whereas corticosteroids may play only an adjunctive role. Consistent, structured monitoring during and after infusion allowed early detection, timely intervention, and prevention of more severe complications.

Conclusion: Even early and seemingly mild symptoms during IV iron infusion may precede a clinically significant hypersensitivity reaction. Prompt, stepwise management with antihistamines and corticosteroids—combined with vigilant monitoring—is essential for safe and effective care.

(2) Centro De Salud Pacífico, Madrid, Espagne

Context: Incidental findings on neuroimaging performed after mild traumatic brain injury (TBI) are increasingly reported, partly due to the growing availability and use of Computed Tomography (CT) in Emergency Departments (ED). Current evidence indicates that up to 2–3% of neuroimaging studies for this cause reveal unrelated intracranial abnormalities, most of them benign. These findings can create diagnostic and emotional uncertainty for patients and clinicians. Family physicians play a key role in identifying red flags, ensuring appropriate referral for acute evaluation, and providing longitudinal follow-up. This report presents the case of a 54-year-old male taxi driver in whom a minor traffic accident led to the incidental detection of an intracranial lesion.

Methods: The patient, with no relevant medical history, reported complete amnesia for a frontal rear-end collision he suffered two days before. Apart from neck pain and mild headache, there were no signs of alarm in the physical and neurological examination. Since episodic amnesia and the possibility of unrecognized transient loss of consciousness, the patient was referred to the ED. Cranial CT excluded acute traumatic lesions but revealed a 1.8-cm right frontal hypodense, non–mass-effect lesion suggestive of an intracerebral nodule. Neurology assessment included Electroencephalogram (EEG), which showed an epileptiform focus in that nodule. The patient was informed and referred for diagnostic evaluation. Primary care assumed ongoing emotional support, clinical monitoring and

coordination across specialties. The diagnostic process remains ongoing.

Originality: This case illustrates how a minor traumatic event may uncover an asymptomatic intracranial lesion. It highlights the essential role of family physicians as the first point of clinical triage and as coordinators of safe, patient-centred care pathways.

Lessons learned and future implications: Increasing neuroimaging use in TBI evaluation is likely to raise incidentaloma detection. Standardized primary-care pathways are needed to guide communication, risk assessment, and referral. Empathetic communication and rapid multidisciplinary coordination may reduce unnecessary interventions and patient's anxiety. Follow-up should incorporate a biopsychosocial perspective to address clinical and emotional impacts.

Discussion: Most intracranial incidentalomas are benign but still pose diagnostic and coordination challenges for Family Physicians.

Conclusion: Their role is essential for risk stratification, continuity of care, and guiding patients safely through the diagnostic process.

(2) Vlc Foundation, Stockholm, Suède

Context: Context The World Health Organization (WHO) highlights existential health (EH) as a core dimension of overall human well-being. EH encompasses meaning and purpose in life, inner peace, connectedness, and hope. It also plays an important role in promoting and sustaining mental health. Objectives To map the current status of EH in Sweden through a public online survey. To investigate whether an online intervention based on Stoic philosophy – guided self-reflection and MindShift exercises can improve EH and prevent or reduce the incidence of newly emerging mental health conditions.

Methods: A public online survey will be conducted in Sweden, announced through traditional media and social media, using the World Health Organization's EH assessment tool (WHOQOL-SRPB-BREF module on spiritual, religious, and personal beliefs). Individuals interested in participating in the intervention will be able to register for weekly 1-hour online sessions over 6 months. Participants will complete EH questionnaires (WHOQOL-SRPB-BREF) and screening tools for depression and anxiety before sessions 1, 12, and 24, and will report any newly diagnosed mental health conditions or other comorbidities. Survey respondents who consent to later follow-up but do not participate in the intervention will form a non-intervention comparison group.

Originality: EH is a relatively recent health aspect introduced by WHO as an area requiring investigation and improvement. This study is therefore both timely and relevant, particularly in an era of rapid digitalization, increasing reliance on AI, and rising existential challenges.

Lessons learned and future implications: We expect that the intervention may improve EH and reduce the proportion of newly emerging mental health conditions, such as depression or anxiety. If effective in Sweden, this approach may be scalable internationally and contribute to strengthening EH worldwide.

Discussion: Maintaining mental health may become increasingly important in times of growing digitalization and the expanding role of AI, alongside rising loneliness, segregation, and heightened risks of various natural or human-made crises.

Conclusion: EH is a key component for a fulfilling and resilient life. Mental health should be supported and sustained, not only treated after illness emerges. This project will explore whether an intervention combining ancient Stoic philosophy with modern MindShift exercises can enhance existential health and help prevent mental health deterioration.

ID 1373- How to develop leadership skills in future general practitioners? A proposal from French general practitioners.

Laura GARCIA SÁNCHEZ-OSORIO, Miriam GARCÍA CERRAJERO

Humt, Terrassa, Espagne

Context: A 28-year-old woman presents with productive cough and left-sided chest pain three days long. Initial chest X-ray is does not show infiltrates, so symptomatic management is started. Three days later, the patient goes to the emergency department with worsening symptoms, as she is found to have markedly elevated CRP (500 mg/L) and procalcitonin (4.8 mg/dL), with left basal crackles. A new chest X-ray shows left lower lobe consolidation with urine antigen negative. She is started on ceftriaxone and azithromycin for community-acquired pneumonia. After clinical and laboratory improvement, she is discharged.

Methods: Five days later, she returns with a 40°C fever and worsening chest pain. She is febrile, with basal oxygen saturation of 96%, decreased breath sounds, and crackles in the lower two-thirds of the left lung. Laboratory results show leukocytosis (9,680/µL), CRP 299 mg/L, and negative procalcitonin. Chest X-ray shows left pleural effusion, confirmed with pulmonary echography. Thoracentesis yields pleural fluid with LDH 1,760 U/L, a pleural/plasma LDH ratio of 8, pleural/plasma protein ratio of 0.59, and pH 7.62, consistent with an exudative effusion. The sample is insufficient for cell count. Despite antibiotics, she persists with daily fevers with chest pain, and persistent elevation of inflammatory markers. Antibiotics are escalated to piperacillin-tazobactam. The latest chest X-ray shows increased, now septated, pleural effusion. A pleural drain is placed, yielding cloudy, serohematic fluid with positive Streptococcus pneumoniae antigen.

Originality: This case shows the complications of pneumococcal pneumonia and their management.

Lessons learned and future implications: This case reviews the diagnosis and management of pulmonary empyema, as well as the importance of adjusting the antibiotic treatment and a proper patient follow-up.

Discussion: The case is oriented as complicated pneumococcal pneumonia with empyema. Antibiotics are adjusted to ceftriaxone. Chest CT shows necrotizing pneumonia with improving effusion. The drain is removed, and she continues antibiotics, later switched to oral amoxicillin for three weeks after clinical improvement, with another chest CT at three weeks in order to decide the next step.

Conclusion: This case illustrates the typical progression and management of complicated parapneumonic effusion and empyema, including the need for prompt drainage and targeted antibiotics.

ID 2287- How to develop Quality improvement capacity in primary care

Gabriela LALIGA BLANCO [(1)] , Sonia REDONDO DE PEDRO [(2)]

(1) Family Medicine Resident, Madrid, Espagne
(2) Family Medicine Attending, Madrid, Espagne

Context: Post-electric shock cardiothoracic symptoms in a 25-year-old female with normal cardiac evaluation.

Methods: A 25-year-old woman, with no significant medical history, presented to Primary Healthcare following an occupational electric shock two days prior. Since the incident, she has experienced chest oppression, asthenia and bradykinesia. On physical examination, cardiopulmonary auscultation was rhythmic without murmurs or additional sounds; transient tachycardia resolving within seconds. No entry or exit point of the electrical current were observed. An electrocardiogram was performed showing sinus rhythm at 80 bpm, narrow QRS, no conduction abnormalities and no repolarization changes. Three days later, chest pain persisted and aphonia appeared without odynophagia. Physical examination revealed normal cardiopulmonary auscultation, normal oropharynx and intense tenderness on

palpation over the sternum and ribs. A Cardiology e-consultation was requested and chest and sternum X – rays were performed with no acute pathological findings. During Cardiology consultations, a new ECG showed sinus rhythm at 67 bpm, PR interval 114 ms without clinical relevance, and a transthoracic Doppler echocardiogram revealed no abnormalities.

Originality: Electrical shocks can produce cardiovascular, neurological and musculoskeletal symptoms of varying severity. In this case, the patient experienced chest pain, asthenia, bradykinesia and aphonia following a low-voltage electrical shock, without detectable electrical or structural changes. The case highlights the usefulness of e-consultations for rapid cardiology assessment and follow-up in Primary Healthcare.

Lessons learned and future implications: This case demonstrates the importance of comprehensive evaluation and follow-up after electrical injuries, even in the absence of abnormal findings in tests performed in Primary Healthcare. Persistent symptoms may require interdisciplinary assessment, and the role of the Primary Care physician is essential for monitoring and coordinating with specialists.

Discussion: Electrical injuries present a wide spectrum of clinical and electrical manifestations, ranging from asymptomatic to life-threatening. In this patient, chest pressure and bradykinesia were not explained by electrical or structural alterations. This confirms that not all symptoms following an electric shock are of cardiological origin, highlighting the importance of thorough patient evaluation.

Conclusion: Comprehensive Primary Healthcare, combined with specialist collaboration via e-consultations, ensures proper management of patients after electrical injuries. Even when tests are normal, symptoms monitoring and follow-up are essential for patient reassurance and preventing complications.

Mellassine Maternal And Child Protection Center, Bechir Hamza Children's Hospital Of Tunis, Tunis, Tunisie

Context: As part of Breast Cancer Awareness Month, non-drug interventions aim to improve the well-being of patients with benign breast disorders or breast cancer. Music therapy is known to reduce stress and anxiety and to enhance emotional well-being. However, few works explore its immediate effect during group sessions.

Objectives: The aim of this preliminary experience was to explore the immediate impact of a group music therapy session on participants' emotional state and well-being.

Methods: The intervention was carried out in a neighborhood facing significant socio-economic challenges and represented a first experience. Forty-two women being followed for benign or malignant breast conditions participated in a single group session led by a certified music therapist. The assessment relied on direct verbal feedback collected before and after the session, focusing on perceived stress,anxiety, relaxation, mood, and emotional support.

Results: A total of 42 women followed for benign or malignant breast pathology. The average age was 50 years (range 32–68) participated in a single music therapy session led by a certified music therapist.Before the session, patients described heterogeneous levels of stress, fatigue, and emotional tension related to their condition and living environment. The session combined guided music listening, live instrumental interaction and moments of relaxation and individual reflection.Immediately after the workshop, all women reported clear benefits: a feeling of calm, reduced anxiety, emotional relief and a strengthened sense of support and safety. The

session was unanimously perceived as soothing and helpful.

Discussion: These observations are consistent with literature indicating that music therapy can provide meaningful emotional and physical benefits to patients with breast conditions. Previous studies have shown reductions in anxiety, depression, as well as physiological parameters such as blood pressure and heart rate in breast cancer patients. Additionally, a clinical trial in women undergoing chemotherapy, 30-minute sessions before each cycle improved quality of life and eased anxiety, depression and side effects like nausea.

Conclusion: This first experience suggests that group music therapy may be a promising complementary intervention for women with breast conditions, especially in socio-economically vulnerable settings. Its immediate benefits support integrating non-pharmacological approaches into patient care. Future sessions should include quantitative evaluation to confirm these preliminary results.

ID 1212- Humanistic and Sustainable Care: A Workshop on Implementing Shared Decision Making with Decision Aids

Ilgin IMIR, Volga KAYMAKCI, Emre TURSUCU, Vildan MEVSIM

Dokuz Eylul University, Faculty Of Medicine, Department Of Family medicine, Izmir, Türkiye

Context: Ear pain is a frequent childhood complaint in primary care, usually caused by benign conditions. In rural settings, however, children's involvement in agricultural activities increases exposure to insects and environmental hazards. When several children present with similar symptoms within a short period, family physicians can identify shared environmental patterns. This case series describes a cluster of children whose acute ear pain was linked to a common agricultural exposure.

Methods: Over three consecutive days, four children aged 5–11 presented to a family health center in a semi-rural district with acute ear pain. Otoscopic examination revealed small insects in the external auditory canal in all cases. Insects were removed manually and with saline irrigation; topical therapy was used when mild inflammation was present. Environmental histories were obtained from families, focusing on outdoor activities and contact with vegetation. All four families independently reported purslane-gathering in agricultural fields during the same week, where children sat or lay on dense vegetation. No systemic symptoms or tick exposure were identified at presentation or follow-up. Families received counseling on insect and tick protection, and the cluster was reported to preventive health authorities.

Originality: This case series highlights an unusual environmental presentation in primary care: multiple children developing insects in the ear canal after participating in the same agricultural activity. It shows how primary care clinicians can detect environmental risks through pattern recognition, even without formal public health alerts.

Lessons learned and future implications: Similar pediatric complaints occurring in clusters should prompt evaluation for shared environmental exposures. In rural areas, routine counseling on insect and tick prevention is essential. Improving environmental history-taking skills can support earlier recognition of vector-related hazards

Discussion: Insects in the ear canal occur more often in rural areas, especially during summer. While isolated cases are usually straightforward, clusters require broader environmental assessment to prevent recurrence and exclude co-exposures such as ticks, which may transmit serious infections.

Conclusion: Environmental history-taking combined with pattern recognition is essential in pediatric primary care. Family physicians should identify shared exposures and provide preventive advice to protect children in agricultural communities. MeSH: Ear Pain; Insect; Environmental Exposure; Children; Primary Care

ID 2289- Hypertensice crisis during paroxetine tapering exacerbated by acute alcohol consumption in a patient with MDD and SA: Successful Outpatient Management

Zeynep Cansu KAÇAR [(1)] , Vildan MEVSIM [(2)]

(1) Department Of Family Medicine, Faculty Of Medicine, Dokuz Eylul University, Izmir, Turkey, İzmir, Türkiye
(2) Dokuz Eylul University, Department Of Family Medicine, Faculty Of Medicine, Izmir,turkey, İzmir, Türkiye

Context: Dermatologic complaints are common in primary care, and localized erythematous lesions are often initially attributed to fungal infections. However, persistent rashes unresponsive to standard therapy may indicate an underlying systemic inflammatory or autoimmune process. Early recognition of atypical cutaneous signs in children can prevent delayed diagnosis of serious rheumatologic disease.

Methods: An 11-year-old girl presented with a 5–6-month history of a persistent erythematous lesion on the lower leg. She had previously received topical and oral antifungal treatments without improvement. On evaluation, detailed history, physical examination, and prior laboratory results were reviewed. Dermatology referral led to a skin biopsy, which confirmed granuloma annulare. Laboratory testing revealed elevated erythrocyte sedimentation rate (ESR). Considering both the biopsy findings and systemic inflammatory markers, the patient was referred to pediatric rheumatology, which confirmed a diagnosis of juvenile idiopathic arthritis. A limitation of the case was the initial narrow focus on superficial infection, delaying consideration of systemic disease.

Originality: This case illustrates an uncommon but clinically significant association between granuloma annulare and juvenile arthritis. While granuloma annulare is usually idiopathic and self-limiting, literature reports links to autoimmune processes in some pediatric patients. Unlike prior reports, this case emphasizes how a dermatologic complaint initially managed as a fungal infection ultimately revealed systemic pathology.

Lessons learned and future implications: Treatment-resistant skin lesions should prompt clinicians to expand the differential diagnosis beyond localized infection. In children, biopsy results and inflammatory markers must be interpreted in the context of potential autoimmune disease. Clear referral pathways between primary care, dermatology, and pediatric rheumatology are essential.

Discussion: This case reinforces evidence that granuloma annulare may serve as a cutaneous manifestation of systemic inflammation. Maintaining clinical vigilance for rheumatologic disease in the context of refractory lesions can facilitate timely diagnosis and treatment, preventing long-term joint damage.

Conclusion: Persistent cutaneous lesions in children should be evaluated holistically rather than as isolated dermatologic problems. Early multidisciplinary collaboration and systemic assessment improve diagnostic accuracy and support optimal patient outcomes.

ID 1389- Hypertension Galaxy Lab: A Global/Cross-Cultural Initiative for Leveraging e-Health in Primary Care

Zeynep Cansu KAÇAR, Vildan MEVSIM

Department Of Family Medicine, Faculty Of Medicine, Dokuz Eylul University, Izmir, Turkey, İzmir, Türkiye

Context: Generalized pruritus is a common complaint in primary care, and scabies is often presumed due to its prevalence and characteristic lesion pattern. However, persistent symptoms after appropriate treatment should prompt clinicians to broaden the differential diagnosis, including sexually transmitted infections (STIs) that may mimic or coexist with dermatologic conditions.

Methods: A 35-year-old male presented with generalized itching shortly after staying away from his usual household. Given the lesion distribution and epidemiological context, scabies was diagnosed and standard therapy initiated. Two weeks later, he returned with ongoing pruritus despite correct treatment. During reevaluation, a more comprehensive

history was obtained that extended beyond accommodation changes to include sexual risk behaviors. The patient then disclosed a suspicious sexual encounter during his time away—information not initially provided. Targeted questioning about genital lesions followed, and a full STI panel was ordered, including syphilis serology, HIV, hepatitis B/C markers, and urine PCR for chlamydia and gonorrhea. This shift redirected clinical thinking from presumed treatment-resistant scabies toward possible STI-related dermatologic manifestations. A key limitation was reliance on a single epidemiological trigger at the first visit, without integrating sexual history early. Nevertheless, the measurable outcome was identification of a high-risk exposure that significantly influenced diagnostic considerations.

Originality: This case highlights how a seemingly straightforward scabies diagnosis may mask STIs, an issue underrepresented in primary care reports. It demonstrates how delayed sexual history-taking can prolong symptoms and obscure the true cause.

Lessons learned and future implications: Structured, nonjudgmental sexual history-taking should be part of the initial assessment of persistent pruritus, particularly in young and middle-aged adults. A systematic approach that considers sexual exposures alongside accommodation history can prevent diagnostic delays.

Discussion: The case reinforces the importance of maintaining a broad differential diagnosis in persistent pruritus and avoiding premature closure—especially when treatment fails. Literature similarly notes that scabies-like symptoms may coexist with, mimic, or distract from STI-related cutaneous manifestations. Persistent itching following appropriate scabies treatment should trigger reconsideration of alternative or comorbid causes.

Conclusion: Incorporating sexual history and STI screening into the evaluation of unresolved itching allows earlier identification of alternative diagnoses and improves patient outcomes in primary care.

ID 1819- Hypoglycemia presenting with acute neurological symptoms in a migrant patient with language barriers: A case-based reflection

Zeynep Cansu KAÇAR [(1)] , Özden GÖKDEMIR [(2)], Vildan MEVSIM [(1)]

(1) Dokuz Eylül University Faculty Of Medicine, Department Of Family Medicine-İzmir (türkiye), İzmir, Türkiye
(2) Izmır Economy University Faculty Of Medicine, Department Of Family Medicine, İzmir, Türkiye

Context: Primary care physicians frequently care for patients with physical and cognitive disabilities, yet the lived experience of disability often remains abstract in routine medical training. To address this gap, our Family Medicine residency program integrates experiential disability awareness training through visits to a Disability Awareness Center in XXX (city), XXX (country). The aim is to foster empathy, reduce bias, and promote patient-centered practice by enabling residents to temporarily experience disability from the patient perspective.

Methods: Description of the experience; the structured program included five consecutive simulations. In the visual impairment module, residents navigated a completely dark room using a white cane, provoking disorientation and revealing reliance on accessible environmental design. The autism spectrum simulation recreated hypersensitivity to light and sound through a short film, inducing cognitive fatigue similar to neurodivergent sensory distress. A separate sensory overload exercise combined loud auditory stimuli with simple tasks, illustrating how concentration difficulties may manifest clinically as anxiety or noncompliance. The dyslexia simulation asked participants to read a deliberately distorted, disordered text, mirroring the decoding challenges faced by individuals with dyslexia. Finally, the mobility impairment exercise required using a manual wheelchair on 6% and 10% slopes, quickly leading to physical exhaustion and heightened awareness of everyday accessibility barriers.

Originality: Unlike single-disability models, this multi-sensory, sequential approach offered a holistic, emotionally resonant experience and is uniquely embedded as a required component of Family Medicine training. Strengths included immersive multi-sensory design, stepwise exposure to diverse limitations, and structured debriefing sessions. While brief simulations cannot replicate lifelong disability, they provided meaningful insight. Qualitative reflections were collected and discussed during residency seminars.

Lessons learned and future implications: Participant family medicine residents reported greater appreciation for environmental and sensory barriers, improved empathy, and increased attention to accessibility in clinical encounters. Incorporating patient narratives and longitudinal follow-up may further reinforce behavioral change.

Discussion: Experiential methods complement traditional didactics by challenging assumptions and deepening residents' understanding of patient realities, potentially influencing communication and shared decision-making practices.

Conclusion: Disability awareness simulations can enrich residency education by cultivating more empathetic, inclusive, and equitable primary care practice.

ID 2285- I only know I know nothing: the non-painful zoster

Ângela PAVEGLIO TEIXEIRA FARIAS, Margarita SILVA DIERCKS, Lucas ABREU CAVERSAN, Fernanda MIRANDA SEIXAS EINLOFT, Scheila MAI, Rosa LEVANDOVSKI, Lena AZEREDO DE LIMA, Deivid VIEIRA SILVEIRA, Laura MACHADO SCOTT

Grupo Hospitalar Conceição-Ghc, Porto Alegre, Rio Grande Do Sul, Brésil

Context: Continuing Education in Health (CEH) promotes evidence-based clinical updating, avoids therapeutic inertia and encourages comprehensive and interprofessional care. The Working Group (WG) for Caring of People with Chronic Conditions of XXX developed the "Guide for Caring in Hypertension and Type 2 Diabetes (DM2)" to support CEH based on the Chronic Care Model (CCM).

Objectives: Establish a CEH based on its own guidelines for qualifying care in Primary Health Care (PHC).

Methods: Pedagogical process supported by active learning methodologies and content based on up-to-date scientific evidence, which systematizes and guides the practice of professionals in the care of individuals with hypertension and DM2 in primary health care. Developed in four stages: 1) Survey of learning priorities chosen by professionals through a questionnaire; 2) Planning of activities (themes definition, target public, pedagogical framework, active learning methodologies, teaching strategies, resources, and schedule); 3) Execution of activities; 4) Evaluation regarding participation, satisfaction, quality of the CEH and skills acquired. We applied questionnaires to 250 PHC professionals. The activities were directed to physicians, nurses, nursing technicians, nutritionists, pharmacists, dentists, and community health agents.

Results: In 2024, 14 CEH were carried out, with 292 participants. In 2025, were developed 19 CEH, with 579 participants. The chosen themes were: CCM; strategies for guiding lifestyle changes; specific and interprofessional care in hypertension and DM2. The evaluations of the professionals who underwent the CEH highlighted that the active learning methodologies, the "Guide for Caring in Hypertension and DM2" compiling the most up-to-date theoretical references, and the sequence of CEH were essential for rethinking their practice and optimizing the comprehensive and interprofessional care of people living with these conditions.

Discussion: The CEH reflects the qualification of clinical practice in PHC. The Guide, available through a QR Code, enables quick review. Consolidating the CCM and the good care practices through CEH is challenging. Structuring a theoretical framework that meets the needs of PHC constitutes a differentiating factor in the proposed CEH.

Conclusion: The CEH for interprofessional teams in PHC enabled the inclusion of practices

and were recognized as important in improving the quality of care for people with hypertension and type 2 diabetes in primary health.

ID 1688- I'm a Dad, Get me out of here: Leadership Lessons from Parenting

Kristian HAMARA

Slovak Society Of General Practice, Bratislava, Slovaquie

Context: This case report describes the diagnostic and therapeutic course of a 42-year-old male patient who initially presented with nonspecific gastrointestinal complaints. Despite an extensive somatic diagnostic workup—including laboratory testing, ultrasound, endoscopic examinations, and CT imaging—no organic cause of the symptoms was identified. A presumed diagnosis of SIBO led to temporary improvement following dietary measures and antibiotic treatment. However, the patient subsequently experienced an unexpected progression of psychiatric symptoms, including sleep disturbances, affective lability, and suicidal ideation. After an acute psychiatric evaluation, a diagnosis of severe depressive disorder was established, and the patient was admitted to a psychiatric clinic. This case highlights the complex interplay between somatic and psychological symptoms and underscores the importance of early recognition of psychiatric comorbidity in patients with long-standing unexplained physical complaints.

Methods: A detailed clinical evaluation was conducted, including comprehensive somatic diagnostics (laboratory tests, abdominal ultrasound, endoscopy, and CT imaging) followed by targeted gastroenterological treatment for suspected SIBO. As the symptom pattern evolved, psychiatric assessment was performed to clarify the emerging affective and cognitive disturbances.

Originality: This case uniquely demonstrates how initially isolated gastrointestinal symptoms can mask an underlying depressive disorder that rapidly progresses to a severe episode with psychotic features. It highlights an uncommon but clinically significant transition from somatic presentations to acute psychiatric decompensation.

Lessons learned and future implications: The case underscores the importance of early psychiatric consideration in patients with persistent, unexplained somatic complaints. It suggests that integrating routine psychosocial screening into somatic diagnostic pathways could facilitate earlier detection of somatized depressive disorders and reduce the risk of progression to severe forms, including suicidal behavior.

Discussion: The observed clinical trajectory illustrates the complexity of mind–body interactions and the potential for somatic symptoms to represent prodromal phases of major psychiatric illness. The case highlights the necessity of interdisciplinary communication between primary care, gastroenterology, internal medicine, and psychiatry to ensure timely intervention and comprehensive patient care.

Conclusion: This case reinforces the value of a holistic, bio-psycho-social approach in everyday clinical practice. Early recognition of psychiatric comorbidity in patients with chronic, unexplained somatic symptoms is essential for preventing escalation into severe depressive episodes and for improving overall diagnostic and therapeutic outcomes.

ID 357- Identification of therapeutic inertia in the management of patients living with Diabetes in Family Medicine Units

Sarra BEN MASSOUD, Amira KHELIL

Hopital De Circonscription De Grombalia, Nabeul, Tunisie

Context: Les patients multitarés, souvent polymédiqués, présentent fréquemment une faible adhésion à leurs traitements, entraînant une mauvaise observance thérapeutique et une augmentation des consultations médicales

Objectives: Notre objectif était de déterminer la prévalence et les facteurs prédictifs de la mauvaise observance thérapeutique (MOT)

chez les patients atteints de maladies chroniques lors des consultations.

Methods: Il s'agissait d'une étude prospective réalisée sur une durée d'un an, incluant des patients adultes présentant une ou plusieurs maladies chroniques traitées pharmacologiquement, suivis à l'hôpital de circonscription de Grombalia. Le niveau d'observance thérapeutique a été évalué à l'aide du questionnaire de Girerd, permettant de distinguer deux groupes : les bons observants (score 0–2) et les mauvais observants (score ≥3).

Results: Nous avons inclus 365 patients, âgés en moyenne de 68 ± 12 ans, avec un sex-ratio de 1,25. Parmi eux, 41 % étaient illettrés, 17,3 % sans emploi, 53,2 % couverts par une assurance maladie et 74,2 % mariés. Les principales comorbidités étaient le diabète (92 %), l'hypertension artérielle (92 %), la dyslipidémie (65,5 %) et l'insuffisance cardiaque (29,3 %). La MOT a été observée chez 52,6 % des patients. Une mauvaise observance thérapeutique était significativement associée au chômage ($p < 0,001$), à l'illettrisme ($p < 0,001$), à l'absence d'assurance maladie ($p < 0,001$), à la dépendance à une tierce personne ($p < 0,001$), à un nombre de comprimés supérieur à trois ($p < 0,001$) et à l'absence de remboursement ($p = 0,003$).

Discussion: Dans notre étude, la mauvaise observance a été estimée à 52,6% des patients. Dans la littérature, la prévalence de la mauvaise observance thérapeutique est variable, elle variait entre 14 et 96%. Ces différences internationales peuvent être expliquées par la différence des facteurs socio-économiques et démographiques dans la gestion de la pathologie. Les disparités entre les régions tunisiennes et les autres pays soulignent la nécessité d'élaborer des politiques de santé sur mesure, tenant compte des particularités économiques et sociales de chaque population.

Conclusion: La mauvaise observance chez les patients polymédiqués nécessite éducation, accompagnement et simplification du traitement.

António Bartolomeu JÁCOMO [(1)], Maria Teresa SILVA [(2)], Miguel VIEIRA [(3)]

(1) Toxrun One Health Toxicology Research Unit Of Cespu, Gandra, Portugal
(2) Faculty Of Medicine Of The Catholic University Of Portugal, Lisbon, Portugal
(3) Center For Bioethics Research / Nova School Of Law Of The University Nova Of Lisbon, Lisbon, Portugal

Context: Artificial intelligence (AI) systems are increasingly used in primary care to support diagnosis, documentation, and treatment planning. While these tools offer operational advantages, they raise significant bioethical and neuroethical concerns. Traditional ethics emphasize autonomy and beneficence, but AI also impacts cognitive processes fundamental to judgment and trust.

Objectives: To review current literature on how AI systems in primary care intersect with neuroethical themes—particularly cognitive offloading, epistemic agency, informed consent, and moral responsibility—and to contrast these with conventional bioethical frameworks.

Methods: A narrative review was conducted using peer-reviewed literature published between 2017–2025. Databases included PubMed, Scopus, and Google Scholar. Inclusion criteria focused on AI ethics in clinical settings, especially in general practice. Literature from neuroethics, decision science, and legal theory was also integrated. Thematic analysis was used to identify and categorize content across four domains: clinician cognition, patient agency, accountability, and governance mechanisms.

Results: AI improves workflow and standardization but introduces risks of automation bias and reduced clinician agency (Cross et al., 2024; Román Collazo et al., 2024). Opaque decision-support systems challenge informed consent when explanations are not cognitively meaningful to patients (Moulaei et al., 2025; Wachter et al., 2017). While bioethical frameworks often treat consent as

procedural, neuroethics highlights how AI affects internal reasoning, trust calibration, and deliberative integrity. Governance responses include explainability mandates and human-in-the-loop designs (Sasseville et al., 2025; National Academy of Medicine, 2023).

Discussion: Neuroethics deepens ethical evaluation by focusing on how decisions are formed cognitively and relationally. In primary care, where trust and narrative reasoning are central, this perspective is essential to understanding AI's practical and moral impact.

Conclusion: AI integration in general practice requires ethical scrutiny beyond normative principles. A neuroethical lens reveals how technology affects the cognitive underpinnings of agency and accountability. Future policy and system design must align with both ethical theory and human cognitive architecture.

Context: Artificial intelligence (AI) is already a buzz topic in primary care, promising help with triage, scheduling, diagnosis and paperwork. Behind the shiny promises sit messy questions about who is in control, who is left out and who takes responsibility when things go wrong. General practitioners (GPs) rarely get to analyse AI tools before they land in daily practice.

Objectives: Spot red flags and missed opportunities when AI tools are pitched to primary care. Use a short set of questions to test whether an AI proposal is safe, fair and worth trusting. Recognise how AI tools can either reinforce or reduce inequities in access and quality of care.Communicate concerns and expectations about AI with managers, developers and patients.

Teaching method and workshop: After a quick, myth busting overview of AI in healthcare, participants jump into small group debate role plays. In each case one team plays the AI pitching company and the other plays management or clinical leadership, negotiating if, when and how to adop

Expected outcomes: Participants will gain confidence in discussing AI projects and will leave with a practical checklist of questions to use when AI tools are proposed in their organisations. They will be better prepared to defend freedom of clinical judgment and equality i

Conclusion: This workshop invites family doctors to share doubts and experiences, to challenge AI promises and to imagine safer, fairer implementations together. It supports primary care professionals to move from passive users to informed partners whenever AI enters their practice.

Context: Family physicians are the healthcare professionals who ensure patients initial access to the care system, maintaining a closer and continuous relationship with each patient. However, this proximity may have negative implications for the physician's mental health, leading to physical and mental exhaustion. Burnout among family physicians is an increasingly common and multifactorial phenomenon, associated with rising workloads, time pressure, clinical complexity and the need to balance multiple non-clinical responsibilities. The literature shows that high levels of burnout compromise care quality, patient safety, professional satisfaction, and the stability of healthcare teams. In this context, it is essential to deepen the understanding of the determinants of burnout and the factors that contribute to the well-being of family physicians.

Objectives: To assess the prevalence of burnout among family physicians working in a Portuguese Local Health Unit (LHU).

Methods: This is an observational, descriptive, cross-sectional study with an analytical component, currently underway. It is based on an anonymous online questionnaire addressed to family physicians and residents working in the LHU. The questionnaire includes demographic and professional data, as well as the Maslach Burnout Inventory – Human Services Survey, validated for Portuguese. Data will be analyzed using descriptive and inferential statistics after the conclusion of data collection.

Results: Although data collection is still ongoing, relevant levels of burnout are expected to be identified, with a high prevalence of emotional exhaustion and depersonalization, and low personal accomplishment. The study also aims to examine the association between these factors and gender, age, organizational model of the health unit and years of professional experience.

Discussion: As data collection is still in progress, a complete analysis and discussion cannot be provided at this stage. Updated results and their interpretation will be presented during the congress.

Conclusion: This study aims to contribute to a deeper understanding of the professional reality of family physicians in Portugal, reinforcing the need for policies and interventions that promote healthy working environments. Investing in physicians' mental health and well-being is an essential pillar for ensuring sustainable, safe, and high-quality primary healthcare.

Department Of Emergency Medicine, Mahmoud Yaacoub Center For Urgent Medical Assistance, Tunis, Tunis, Tunisie

Context: Seizures are an infrequent complication of intoxication, it may be caused by a wide range of drugs and toxins.

Objectives: This study aimed to describe the epidemiological and clinical profile of patients presenting to the emergency department (ED) following acute intoxication associated with a seizure.

Methods: This was a retrospective study conducted over a 5 year period from October 2020 to September 2025, in the ED of Mahmoud Yaacoub Center for urgent medical assistance. We included patients aged from 14 and over who consulted for seizures after acute intoxication. Data regarding demographic, clinical history, characteristics of the intoxication type of molecule and presumed ingested dose, clinical presentation, consultation delay, seizures before or during the consultation and the anti-seizure treatment used and were collected and analyzed.

Results: A total of 68 patients were included, predominantly male (58.8%), with a median age of 29 years. Epilepsy history was present in 14.9%, with 55% discontinuing antiepileptic

treatment. Substance misuse was reported in 39.7%, mainly cannabis (65.4%), pregabalin (46.2%), and cocaine (19%). Primary exposure routes were drug ingestion (63.2%) and carbon monoxide inhalation (29.4%). Causes included recreational use (33.8%), accidental intoxication (32.4%), and suicide attempt (25%). Main substances implicated included pregabalin, cannabis, carbamazepine, cocaine, and heroin. Most seizures (92.6%) occurred before consultation, with 93.7% resolving spontaneously; 10.3% experienced seizures during consultation. Initial clinical exams were generally stable. Regarding outcomes, 43.8% were admitted to intensive care, 31.3% discharged home, and 26.6% referred for follow-up, mostly to neurology and addiction services. Eleven patients (17.2%) referred to other EDs, and 4.7% left against medical advice.

Discussion: These findings show that intoxication associated with seizure occur mainly in the recreational substance use or carbon monoxide exposure, with most episodes resolving spontaneously before medical evaluation. This study highlight the need for improved prevention and monitoring of substances involved such as cannabis, pregabalin, and cocaine and also targeted neurological and addiction follow-up.

Conclusion: Seizures noted before the consultation were reported in over half of the cases, and were significantly resolved spontaneously, while few patients experienced seizures during the consultation and required anti-epileptic treatment.

ID 1582- Impact of Antiretro Viral Treatment initiation on quality of life in people living with HIV: Evidence from a National Tertiary Infectious Hospital

Mihaela DILAN, Dorin FARCĂU

Third Pediatric Department, Emergency Hospital For Children, Cluj-napoca, România, Cluj-Napoca, Roumanie

Context: Unconjugated hyperbilirubinemia in adolescents with chronic inflammatory disorders may suggest hemolysis, hepatocellular injury, or immune-mediated hepatobiliary disease. In patients on biologic therapy, distinguishing benign hereditary conditions from drug-related adverse effects is crucial. We describe evaluation of mild scleral icterus in a 16-year-old with ulcerative colitis.

Methods: A 16-year-old female with ulcerative colitis maintained on anti-TNF therapy presented for routine follow-up. Mild scleral icterus was noted. Laboratory tests revealed isolated elevation of total bilirubin, predominantly unconjugated. Hemoglobin, reticulocyte count, peripheral smear, lactate dehydrogenase, and haptoglobin were normal, excluding hemolysis. Liver enzymes, cholestatic markers, and coagulation parameters were within normal limits. Autoimmune serologies (ANA, AMA, ANCA) were negative, making immune-mediated hepatobiliary disease unlikely. Imaging was not indicated. Persistent isolated unconjugated hyperbilirubinemia with normal liver function prompted suspicion of a hereditary disorder. Genetic testing confirmed a UGT1A1 variant compatible with Gilbert syndrome.

Originality: Although Gilbert syndrome is common, its recognition in adolescents with inflammatory bowel disease is challenging, as mild icterus may be misinterpreted as drug toxicity. Few pediatric cases highlight diagnostic uncertainty in the context of biologic therapy, making this case clinically relevant.

Lessons learned and future implications: Early bilirubin fractionation and prompt exclusion of hemolysis are essential. Recognizing benign hereditary hyperbilirubinemia avoids unnecessary discontinuation of effective therapy and extensive hepatobiliary investigations.

Discussion: Benign metabolic conditions can mimic adverse drug effects in patients on biologics. A structured diagnostic approach—evaluating hemolysis first, followed by autoimmune and cholestatic markers, and concluding with targeted genetic testing—ensures accurate diagnosis while preserving therapy. Clinical stability and normal hepatic parameters confirmed the benign nature.

Conclusion: In adolescents with ulcerative colitis, isolated unconjugated

hyperbilirubinemia should raise consideration of Gilbert syndrome. Accurate recognition allows safe continuation of therapy and reinforces the importance of a structured, stepwise diagnostic evaluation.

ID 1456- Impact of Extension Projects in the School Health Program: Playful Activities as a Tool for Addressing Mental Health in Adolescents in Primary Care

Jesús Francisco ARZÚA MOYA

Sergas, Boiro, Espagne

Context: Clinical supervision during emergency department shifts is both a legal and educational requirement in residency programs. However, the 2024 nationwide survey conducted by Asociación MIR España (AME) identified widespread inadequate supervision among Spanish residents. Since then, AME has carried out national advocacy, media campaigns, and institutional negotiations aimed at improving supervision standards. A follow-up survey in 2026 was launched to assess whether supervision quality has changed over time.

Objectives: To compare supervision levels reported by residents in 2024 and 2026, and to evaluate whether advocacy actions by AME were associated with improvements in training conditions and perceived patient safety.

Methods: A repeated cross-sectional online survey was distributed nationally between April and June 2026 using social media, institutional mailing lists, and resident networks. Eligible participants included: 2nd-year residents of all specialties 2nd–4th-year Family Medicine residents The questionnaire replicated the 2024 items to allow direct comparison. Variables included type of supervision, availability of attending physicians, supervision by specialists vs. non-specialists, and perceived safety. Descriptive statistics and comparison of proportions were performed. Preliminary results are presented.

Results: A total of X,XXX responses were received from XXX hospitals (data collection ongoing). Compared with 2024 results (adequate supervision: 28.6%, poor/absent: 71.4%), preliminary 2026 data show: Increase in adequate supervision (provisional improvement of +X–X percentage points). Reduction in residents left alone overnight, especially in regions previously identified as high-risk. Slight decrease in supervision by non-specialists. Residents increasingly reported that professional organizations and advocacy efforts had raised awareness among hospitals and departments.

Discussion: Early findings suggest a potential positive trend in supervision quality following two years of national advocacy. However, significant variability persists between hospitals and regions. Continued monitoring and regulatory action remain necessary to ensure equitable training conditions and patient safety.

Conclusion: Preliminary 2026 data indicate an improvement in clinical supervision during emergency shifts compared with 2024. Advocacy by resident organizations may contribute to these changes, highlighting the value of national monitoring and policy engagement in strengthening medical training.

ID 1936- Impact of Gender Norms on Women's Care Pathways: From Sexist Biases to Medical Violence

Aiste ZIAUGAITE, Gintare SIAUDIKYTE

Lithuanian University Of Health Sciences (lsmu), Faculty Of Medicine, Department Of Family Medicine, Kaunas, Lithuania, Kaunas, Lituanie

Context: Lyme disease is a common tick-borne infection in Europe, with erythema migrans serving as the primary clinical criterion for early diagnosis. However, many patients do not recall a tick bite, and early cutaneous manifestations may lack the classic annular or target-like appearance. Such atypical lesions can resemble allergic dermatitis, cellulitis, or fungal infection, contributing to diagnostic delay in family medicine. Early recognition in primary care is essential, as prompt antimicrobial treatment

prevents progression to neurological, cardiac, or musculoskeletal complications.

Methods: We report the case of a woman in her 50s who presented with a 6–7 day history of fatigue, low-grade fever, diffuse headache, and a 7–8 cm erythematous patch on the lateral thigh. She did not recall a tick bite but reported frequent outdoor gardening. The lesion was non-pruritic, irregularly shaped, and poorly demarcated without central clearing. It was initially diagnosed as allergic dermatitis, and topical corticosteroids were prescribed. Persistent symptoms and lesion enlargement prompted re-evaluation four days later. Serologic testing (ELISA) was performed, and empirical doxycycline was initiated based on clinical suspicion. Clinical response and follow-up outcomes were monitored.

Originality: This case highlights an atypical presentation of early Lyme disease mimicking allergic dermatitis in a patient without a known tick bite. It emphasizes the diagnostic challenges posed by non-classic erythema migrans and demonstrates the limited utility of early serologic testing, which may yield false-negative results.

Lessons learned and future implications: Atypical erythema migrans can occur without the characteristic annular morphology, and absence of a recalled tick bite does not exclude Lyme disease. Early serology may be negative, making clinical judgement crucial. Empirical treatment based on clinical suspicion can prevent progression to disseminated disease. Future efforts in primary care should focus on improving clinician awareness of atypical presentations and enhancing diagnostic pathways.

Discussion: This case illustrates the diagnostic complexity of early Lyme disease when cutaneous findings are subtle or misleading. The initial misclassification as dermatitis reflects common challenges in primary care. Reassessment incorporating symptom progression, epidemiological exposure, and lesion evolution enabled timely diagnosis and treatment.

Conclusion: Atypical erythema migrans may lead to diagnostic delay. Careful clinical assessment and early empirical therapy are essential to prevent disease progression.

ID 711- Impact of initial symptoms - cutaneous or musculoskeletal - on clinical characteristics, comorbidities and diagnosis delay in Psoriatic Arthritis: data from Stockholm COMPASS Cohort

Yosra AZZABI, Camillia JEDDI, Mohamed KILANI, Hatem EL GHORD, Hafedh THABET

Department Of Emergency Medicine, Mahmoud Yaacoub Center For Urgent Medical Assistance, Tunis, Tunis, Tunisie

Context: Neuroleptic Malignant Syndrome (NMS) is a severe and potentially life-threatening reaction to neuroleptic medications. Understanding the patterns of neuroleptic use and associated risk factors is crucial for early diagnosis and prevention of extrapyramidal complications

Objectives: To describe the neuroleptic and antiparkinsonian drugs prescribed to patients evaluated for suspected NMS and identify the causative factors associated with different neuroleptic agents.

Methods: This was a retrospective, observational, XX-center study conducted in the ED of XXX over a five year period from January 2020 to october 2025.Data were collected on neuroleptic and antiparkinsonian drug prescriptions, including specific molecules, co-prescriptions, and identified causes of adverse reactions.

Results: The most frequently prescribed agents were butyrophenones (41.5%), followed by fluphenazine (22.3%) and risperidone (19.1%). Other neuroleptics were less commonly used: phenothiazines (9.6%), olanzapine (3.2%), amisulpride (2.1%), and aripiprazole (1.1%).Regarding antiparkinsonian medications, 46.5% of patients received such treatment. Biperiden accounted for 45.5% of prescriptions, while trihexyphenidyl was administered to only 3 patients (3%). Analysis by molecule showed that butyrophenones were almost always given without antiparkinsonian agents (rate near 1%),

increasing the risk of extrapyramidal symptoms. Fluphenazine was combined with Biperiden in 66% of cases but rarely with Trihexyphenidyl (near 2%), whereas risperidone was paired with antiparkinsonian drugs in only 15% of cases, with no use of Trihexyphenidyl.The identified causes of adverse events varied by neuroleptic agent.Butyrophenones were linked to overdose, rapid dose escalation, or accidental cumulative intake. Fluphenazine was involved in several overdoses of Fluphenazine (75 to 200 mg), withdrawal of Biperiden, and various therapeutic errors. Risperidone was associated with overdose, abrupt therapeutic changes, or isolated adverse reactions. Amisulpride was related to accidental overdose; olanzapine with concomitant Chlorpromazine overdose; and other molecules were implicated sporadically.

Discussion: Among confirmed NMS cases, butyrophenones were the most frequently implicated neuroleptics, followed by fluphenazine and risperidone often in the context of absent antiparkinsonian co-treatment, overdose, or dosage changes. The limited use of trihexyphenidyl and inadequate administration of Biperiden in several high-risk patients constitute major aggravating factors.

Conclusion: These findings underscore the importance of strict therapeutic monitoring, appropriate use of antiparkinsonian agents, and heightened vigilance during dose adjustments.

ID 1808- Impact of patient enrolment on preventive care uptake in primary care

Jesús Francisco ARZÚA MOYA

Sergas, Boiro, Espagne

Context: Acute abdominal pain is a frequent presentation in primary care, and although most cases are benign, some require urgent surgical attention. Recognising early warning signs is essential to prevent complications. Umbilical hernias are common findings in general practice, but their progression to incarceration can be sudden and initially subtle.

Methods: A middle-aged adult attended primary care with acute periumbilical pain that had started a few hours earlier while lifting a heavy object. The pain had progressively intensified and was accompanied by nausea without vomiting or fever. His history included a long-standing reducible umbilical bulge with no previous complications. On examination, he appeared uncomfortable. A firm, tender swelling was palpable at the umbilicus, now irreducible and mildly erythematous. Bowel sounds were present, with no generalized peritoneal signs. Vital parameters were stable. The abrupt change in symptoms and loss of reducibility raised suspicion of incarceration and possible early strangulation. The patient was immediately referred for urgent surgical assessment. Imaging confirmed an incarcerated umbilical hernia. Same-day surgical repair was performed, and postoperative recovery was uneventful.

Originality: While umbilical hernias are common, their transition from a stable, reducible mass to an acute complication is unpredictable. This case illustrates a highly typical scenario for primary care (an everyday condition that becomes an emergency) highlighting the diagnostic reasoning and timely decision-making expected in general practice. The narrative is deliberately generalizable and not tied to identifying details, ensuring broad relevance.

Lessons learned and future implications: Any new pain, tenderness, or irreducibility in a known hernia should prompt urgent evaluation. Patient education on warning signs may reduce delays in seeking care. Strengthening coordination between primary care and emergency services can further improve outcomes for abdominal wall emergencies.

Discussion: Differential diagnoses for acute periumbilical pain include abdominal wall strain, localized infection, strangulated hernia, and gastrointestinal pathology. In this case, careful physical examination guided management. Evidence supports early referral to avoid complications such as strangulation, ischemia, and bowel obstruction.

Conclusion: Primary care is fundamental in detecting early signs of surgical emergencies. Recognizing changes in a chronic hernia's characteristics enables rapid intervention and prevents serious complications, underscoring the critical role of general practitioners in acute care pathways.

Abidemi OGUNSOLA, Anjla SHARMAN, Pooja SHETYE

Nhs, Northampton, Royaume-Uni

Context: An increasing number of General Practice (GP) Doctors are entering training with limited experience working within the country chosen for training. These Doctors are often international medical graduates from non-primary care settings and frequently require additional support to adapt to the structure and primary care working culture. Recognising this transition challenge, we developed and piloted a structured learning programme to support GP Doctors with fewer than six months of experience working in the country at the start of their training. The pilot provided a 4-month placement where Doctors had some of their clinical time replaced with additional education time on key GP domains and contextual topics. In preliminary findings, trainees reported significantly increased confidence in navigating the local systems, understanding the GP role in the wider healthcare structure, and engaging safely with primary care processes. Qualitative feedback highlighted the value of peer discussion, contextual learning, and space for reflection. This pilot demonstrates that a structured, early orientation programme and contextual learning can ease the transition for Doctors new to the country and improve their confidence and engagement. Embedding such initiatives into medical education could enhance educational equity and patient safety, not only regionally or nationally but also internationally.

Objectives: Share challenges and strategies to support learners new to the region. Explore the rationale and design of the structured learning pilot. Review key findings from pilot evaluation. Discuss how similar models could be adapted for use across regions.

Teaching method and workshop: Presentations outlining pilot, rationale, curriculum content, and evaluation findings. 30 minutes Group discussion and to share good practices and identify barriers to implementation. 30 minutes

Expected outcomes: Recognise the challenges faced by new GP trainees and analyse contextual factors. Engage in international and cross-regional learning by sharing innovations, experiences, and good practice examples Reflect on local onboarding and induction processes,

Conclusion: Structured learning intervention can support new trainees with limited local experience, improving early adaptation and well-being. Further evaluation with larger cohorts will help refine content and assess long-term impact on performance and patient care.

Context: Toluene is a solvent often used in paints and industrial cleaning. In closed spaces, inhaling its fumes can quickly cause brain and metabolic problems.

Methods: An 18-year-old worker was found unconscious in a painted tanker after breathing toluene fumes. He had acid–base disturbance but improved with oxygen, fluids, and monitoring. He recovered fully without complications

Originality: This case shows an uncommon combination of acid–base disorders after acute toluene exposure. Few reports describe such full recovery after prolonged exposure

Lessons learned and future implications: Every minute counts in toluene exposure. Awareness and prevention can turn a deadly risk into a story of full recovery

Discussion: An 18-year-old male smoker with no significant past medical history was brought to the ED with altered mental status following a workplace accident. He had been working inside a newly painted tanker truck and was found unconscious at the scene. His last recollection was at approximately 10am., and he was discovered the following day at around 6:00 a.m., indicating a period of unconsciousness of 16 hours. Evidence of urinary incontinence was noted. On initial examination he was alert but euphoric (GCS 15/15), with normal neurological findings. His SBP was 120 mmHg DBP was 80 mmHg, heart rate was 85 bpm, and SpO_2 was 100% on AA.Serial arterial blood gas (ABG) analyses demonstrated progressive metabolic derangement. The initial ABG showed metabolic acidosis with partial respiratory compensation (pH 7.35, HCO_3^- 11.5 mmol/L, lactate 5 mmol/L). A subsequent ABG revealed a mixed picture characterized by respiratory alkalosis superimposed on a high–anion gap metabolic acidosis (pH 7.48, $PaCO_2$ 13 mmHg, HCO_3^- 9.7 mmol/L). A third measurement confirmed persistent alkalemia (pH 7.47) despite further bicarbonate depletion (HCO_3^- 8 mmol/L), indicating ongoing metabolic acidosis with sustained respiratory alkalosis. The rest of the laboratory findings were within normal range. A brain CT was performed and freaked no abnormalitiesThe patient was admitted to the ICU a for close monitoring and supportive management and was discharged the following day with favorable outcome

Conclusion: Early recognition, prompt correction of metabolic imbalance, and close monitoring are critical especially in cases of prolonged exposure and initial loss of consciousness.

(2) Sas, Jerez De La Frontera, Espagne

Context: Transient neurological events in young adults present a diagnostic challenge in primary care, particularly when vascular risk factors are absent. Although sometimes attributed to benign causes, brief recurrent focal deficits may represent transient ischaemic attacks (TIA). Primary care is essential for early recognition, timely referral, and follow-up.

Methods: A healthy man in his late twenties consulted after three short episodes of left-sided weakness and speech disturbance occurring within one day. Each lasted under ten minutes and resolved completely. He denied headache, fever, trauma, or substance use. On examination he was asymptomatic and neurologically intact. Vital signs and cardiovascular findings were normal. Initial blood tests and multimodal CT showed no abnormalities. Continuous cardiac monitoring detected no arrhythmias, and conventional echocardiography was unremarkable. Given the recurrent, focal nature of the symptoms, a bubble-contrast transcranial Doppler was requested, revealing a right-to-left shunt. Outpatient evaluation included brain MRI (normal) and transoesophageal echocardiogram confirming a patent foramen ovale (PFO) with microbubble passage into the left chambers. He was started on antiplatelet therapy and referred to cardiology for further management.

Originality: The case illustrates a frequent but often under-recognised cause of transient deficits in young adults. Its originality lies not in rarity, but in demonstrating how apparently isolated episodes with normal initial testing can conceal a relevant cardiac source of embolism. The narrative emphasises clinical reasoning in

primary care rather than highly specific details, making the case widely applicable.

Lessons learned and future implications: Stereotyped focal neurological episodes in young patients should prompt structured assessment for possible TIA. Early consideration of intracardiac shunts can prevent diagnostic delay. Strengthening access to Doppler screening and clear referral pathways may improve care. The case highlights the importance of continuity and longitudinal assessment in primary care.

Discussion: Although migraine aura, focal seizures, metabolic disturbances, and functional symptoms may mimic TIA, clustering of brief unilateral deficits strongly supports a vascular mechanism. When routine studies are normal, PFO should be considered as a potential route for paradoxical embolism.

Conclusion: Primary care has a central role in recognising transient neurological symptoms in young adults. Early identification of PFO as a possible cause enables timely prevention strategies and may reduce long-term cerebrovascular risk.

ID 768- Implementation of a rapid antigen test for community-acquired pneumonia diagnostics in Primary Care. A preliminary multi-centre study

Geraldine Juliette ECKARDT, Marina ROVIRA, Angela MARTINEZ-PEREZ

Consorci Sanitari D'atencio Primaria Barcelona Esquerra, Barcelona, Espagne

Context: Scabies is a dermatosis caused by Sarcoptes scabiei. It might affect more than 200 million people worldwide. In Europe, an increase in cases has been observed since the COVID-19 pandemic. Despite this, the postpandemic evolution of cases and the prescription of acaricides in our primary care setting is unknown. Aditionally ivermectine was first licensed in Spain in June 2021.

Objectives: To assess the trend in scabies incidence; and to analyze the use of acaricidal treatments prescribed in primary care.

Methods: An observational-population-based, retrospective, study was conducted. Review of aggregated anonymous data of scabies, attended at urban 3 primary care centers (C1,C2,C3) during 2019–2024. Data on acaricidal drugs were obtained from our Pharmacy Accountancy and was available until 2023. Inclusion criteria: Registered diagnosis of scabies (as per ICD-10:B86). No exclusion criteria was considered. Ethics: Data were anonymous. No review of medical records was performed. Our local ethical commetee granted approval in November 2024 (CEIm:HCB/2024/1167).

Results: Between 2019-2024, a total of 1,824 patients were diagnosed with scabies, mostly women (n =976,53.4%). Mean age was 44.54(SD 15.62). The overall incidence was 469 cases/x5:: C1 469cases/x5; C2 427cases/x5; C3 521cases/x5..The highest number of cases was recorded in 2023 (812cases/x5). During 2019–2023 most patients received 5% permethrin cream (n packages prescribed-dispensed=2,337), and ivermectin accounted for n=2,217 packages prescribed-dispensed between June/2021-December/2023. By center, prescriptions varied: 5%-permethrin: C1 n=843, C2 n=660, C3 n=825; Ivermectin: C1 n=739, C2 n=728, C3 n=678. Ivermectin use raisd during 2023 (n=1308 ivermectin vs n=818 5%-permethrin/packages prescribed-dispensed).

Discussion: Our scabies incidence data align with outbreaks reported by the Catalan Public Health Agency, but our study covers a longer period based on individual diagnoses. As limitations non-pharmacological management could not be evaluated, and contact tracing could not be assessed. In our study women seemed more affected, unlike global data. Despite similar incidence across centers, medication prescriptions varied widely. C1 showed the highest drug use and incidence in 2023, suggesting an unreported outbreak. Some patients received multiple packages of 5%-permethrin cream, suggesting repeated applications. However, ivermectin became the most commonly dispensed drug.

Conclusion: Epidemiology of cases and drug-prescription may guide resource planning.

Additionally,monitoring repeated applications and treatment adherence is advisable.

Luana PINHO, Clara FERREIRA, Ana SANTOS, Cátia SOUSA

Usf Rainha D. Tereza, Albergaria-A-Velha, Portugal

Context: Trimethylaminuria, also known as fish-odor syndrome, is a rare metabolic disorder characterized by the inability to convert trimethylamine, a strongly odorous compound, into its odorless derivative, trimethylamine N-oxide. The accumulation of trimethylamine in the body leads to a strong fish-like odor. Although clinically benign, the disorder has a significant psychosocial impact, affecting self-esteem, social interactions, and overall quality of life.

Methods: This case describes the assessment of a female infant presenting to primary care with a recurrent fish-like body odor noticed shortly after the introduction of fish at 7 months of age. The evaluation included clinical history, physical examination, dietary trials conducted at home under medical guidance, and referral to a specialized Metabolic Diseases Clinic. The purpose was to clarify the cause of the odor and its reproducibility. A multidisciplinary approach involving primary care, nutrition and medical genetics allowed structured observation of symptom resolution with dietary avoidance and recurrence with reintroduction. Genetic analysis confirmed FMO3 deficiency, which encodes the enzyme flavin-containing monooxygenase 3. Measurable outcomes consisted of complete symptom remission after dietary modification and successful implementation of a long-term management plan.

Originality: Unlike most reported cases, which are diagnosed later in childhood or adulthood, this case highlights an unusually early clinical suspicion and confirms the value of primary care in recognizing subtle signs of trimethylaminuria, that is rarely described in the literature.

Lessons learned and future implications: This case emphasizes the importance of early clinical suspicion and dietary evaluation in infants with unexplained body odor. The role of Family Medicine is also important to manage psychosocial impact of this condition within the family and community throughout life.

Discussion: This case illustrates the diagnostic challenge of trimethylaminuria in infancy, particularly when symptoms are subtle and triggered by early dietary changes. It reinforces the need to consider metabolic causes in atypical body odor and highlights the value of coordinated care in achieving timely diagnosis.

Conclusion: This case emphasizes the importance of early clinical suspicion and dietary evaluation in infants with unexplained body odor, encouraging greater awareness in primary care and supporting earlier referral pathways to improve long-term management.

Yosra AZZABI, Camillia JEDDI, Mohamed KILANI, Hatem EL GHORD, Hafedh THABET

Department Of Emergency Medicine, Mahmoud Yaacoub Center For Urgent Medical Assistance, Tunis, Tunis, Tunisie

Context: Patients referred to ED for suspected Neuroleptic Malignant Syndrome (NMS) often present with clinical instability and marked biological abnormalities. Understanding their biological profile is essential to support diagnosis and guide early management.

Objectives: To describe the clinical parameters and biological findings observed at ED admission in patients evaluated for suspected NMS.

Methods: This retrospective, observational, XXcenter study was conducted in the xxx over a five-year period from January 2020 to October 2025. Vital signs, neurological findings, laboratory results—including CPK, LDH, ASAT,

renal markers, electrolytes, CRP, hematology—along with ECG data, treatments, and final diagnoses were collected and summarized

Results: On arrival, vital signs were stable and consciousness was preserved, with normal oxygenation, hemodynamics, and a median GCS of 15.Hyperthermia was present in 19.2% of patients, with a median temperature of 37.1 °C. Pupils were reactive in 88.9% of cases. Extrapyramidal signs remained frequent, including rigidity (45.5%), tremor (19.2%), akinesia (10.1%), and cogwheel rigidity (5.1%). Altered consciousness was noted in 15.2% of patients. Biologically, the profile showed clear signs of muscle injury and metabolic stress. Creatine phosphokinase (CPK) was highly elevated (median 739 IU/L, up to >100,000 IU/L), and lactate dehydrogenase (LDH) was also increased (median 226 IU/L [38–5,572]). Aspartate aminotransferase (ASAT) reached up to 1,812 IU/L, consistent with muscle rather than liver involvement.Renal function was generally maintained, though renal impairment was identified in 8% of patients,with creatinine at 67 µmol/L [7.1–244] ,and urea 4.15 mmol/L [1.2–26.7]. Electrolytes were stable: sodium 140 mmol/L [125–163], potassium 3.9 mmol/L [2.06–5.95], and chloride 105 mmol/L [94.3–137]. Inflammation was mild, with C-reactive protein (CRP) at 7.25 mg/L [0.16–224]. Hemoglobin was 14.2 g/dL, leukocytes 10,500/mm³, platelets 255,000/mm³, and the capillary blood glucose measurement ratio remained stable at 1.10 [1.00–1.21].

Discussion: Clinical presentation was mostly stable, but two major findings were prominent: fever in 19.2% of patients and significant rhabdomyolysis with markedly elevated CPK. Aside from these key abnormalities, other systemic parameters, including electrolytes and renal function (8% impairment), remained largely normal.

Conclusion: Suspected NMS cases showed high muscle enzymes with preserved renal function and mild inflammation, helping support early recognition and appropriate management

ID 1754- Implementing a cross-border teaching project for practical year general practise teaching

Roisin DILLON, Lisa HINTON, Ariel WANG, Woods CATHERINE, Barnes REBECCA, Anderson-Kittow REBECCA

University Of Oxford, Oxford, Royaume-Uni

Context: Demand for urgent primary care services for children has risen substantially, yet the quality and safety of communication during brief, high-risk consultations is uncertain. Safety-netting advice is a tool to manage risk and includes information to support recognition of deterioration, ongoing management and when and where to seek further help. This is considered central to safe paediatric care, but its use in urgent primary care is not well described.

Objectives: This scoping review aims to map existing evidence on how safety-netting information is communicated for acutely unwell children in urgent primary care in order to answer the primary research question: what barriers and enablers can be identified across the literature to effective safety-netting communication in paediatric patients seeking urgent primary care.

Methods: A scoping review following Joanna Briggs Institute guidance and the Arksey & O'Malley framework reported according to PRSIMA-ScR. Studies included examined communication of safety-netting or related safety information for children (<18 years), parents/caregivers and/or clinicians in urgent primary care settings (including NHS 111, GP out-of-hours and urgent treatment centres).

Results: From 4,210 records, 15 studies (1972-2023) were included, predominantly from the UK and the Netherlands, with most using qualitative methodology. Barriers to effective safety-netting included inconsistent advice, time pressure and limited continuity, mismatched expectations between clinicians and parents and difficulty assessing parental ability to act on advice. Enablers included simple, layered information, delivered in multiple formats, clear opportunities for re-contact, explicit exploration of parental

expectations, validation of parental expertise and shared decision-making about what to do if things get worse.

Discussion: Safety-netting communication is highly valued by families but is variably and sometimes inconsistently delivered. This is shaped by system pressures and differing expectations of risk management, responsibility and reassurance Current evidence is largely descripted and there is very limited exploration of children's perspectives or expectations of care.

Conclusion: Safety-netting communication for acutely unwell children in urgent primary care is central to perceived safety and reassurance but remains inconsistent in practice. Primary care teams could improve this experience by adopting brief, structured safety-netting providing clear written or visual materials and explicitly addressing parental expectations and need for reassurance.

(2) Faculty Of Medicine, University Of Porto, Porto, Portugal
(3) Universidad De Zaragoza, Zaragoza, Espagne
(4) İstanbul Üniversitesi-Cerrahpaşa, Istanbul, Türkiye
(5) Federal University Of Goiás, Goiás, Brésil

Context: The incorporation of digital health technologies in primary care settings is often seen as a means of addressing these ever-increasing needs while doing so in a sustainable manner. Current evidence suggests a gap exists between what is being taught to PCPs about the use of digital health tools and the actual challenges they face in routine care.

Objectives: 1. To better understand the digital health training needs and preferences of PCPs. 2. To identify key digital health topics, effective teaching methods, modes of delivery, and evaluation tools/metrics which should be prioritised for inclusion in future training curricula 3. To identify key stakeholders who need to be involved in order to integrate relevant changes in training programmes.

Methods: Focus groups with PCPs from an international background with experience using digital health tools were conducted, audio-recorded, and transcribed. Thematic analysis was performed afterwards to identify any prominent themes.

Results: A total of 36 PCPs participated in the study across focus group sessions, (n=5) conducted during the WONCA 2024 conference (n=3), and remotely (n=2). Preliminary thematic analysis has highlighted the importance of integrating standardised digital health skillset training early on, balancing the use of digital health tools with traditional care delivery means, helping PCPs recognise data protection and confidentiality responsibilities, and the need for PCPs to be able to critically evaluate the efficacy and safety of digital health tools.

Discussion: There remains a notable gap between introducing new digital health tools and ensuring the current PCP workforce can make the most use out of them safely. Bridging this will require concerted effort throughout a PCP's medical training and necessitate a multi-faceted approach. Doing so will help hasten digital health competency becoming routine, akin to other clinical skillsets current trainees are expected to be proficient in.

Conclusion: As our understanding of digital health tools and their use proliferates, the skillset of the modern PCPs must likewise evolve to keep pace. Only by providing practical, relevant, and up-to-date training can we ensure PCPs are trained to use these tools comfortably and are best equipped to address the changing needs and expectations of patients for safe and efficient primary care.

ID 1771- Implementing a Point of Care Ultrasound (POCUS) teaching program in the General Practice residency curriculum

Sheila Torquato HUMPHREYS [(1)], Maria Teresa SILVA [(2)], Miguel VIEIRA [(1)]

(1) Nova School Of Law Of University Nova Os Lisbon, Lisbon, Portugal
(2) Faculty Of Medicine Of The Catholic University Of Portugal, Lisbon, Portugal

Context: Space agencies like NASA and ESA have developed advanced telemedicine tools to support astronaut health. These include autonomous diagnostics, wearable sensors, AI-driven triage, and satellite connectivity. Many of these innovations are now being transferred to civilian health systems and offer solutions to persistent challenges in rural primary care—especially in under-resourced or geographically isolated regions. Yet the legal, ethical, and policy implications of these transfers remain underexplored.

Objectives: To review and synthesize academic, technical, and policy literature on how space-derived telemedicine technologies can enhance rural primary care systems in Europe and globally, with a focus on patient autonomy, equitable access, and ethical deployment.

Methods: A structured narrative review was conducted using peer-reviewed databases (PubMed, Scopus, JSTOR), agency reports (NASA, ESA, WHO, UNOOSA), and legal policy briefs (EU GDPR, EHDS). Inclusion criteria: 1) relevance to space-originated health innovations, 2) application to remote or rural healthcare delivery, 3) published between 2000–2025. Exclusion: conceptual-only space medicine studies without Earth-application context. Literature was analyzed thematically across three domains: technology, ethics, and policy.

Results: Key technologies include AI decision-support, tele-ultrasound, holoportation, satellite-based diagnostics, and non-contact vital-sign monitors. ESA/NASA spin-off tools have been piloted in rural and disaster-response settings. Ethical challenges include ensuring informed consent, data privacy, and equitable rollout. Legally, GDPR and emerging EU health-data regulations require encrypted, jurisdiction-specific handling of biometric data. Policy frameworks increasingly support cross-border telehealth, but licensing and funding barriers persist. Community engagement and training are crucial to ensure adoption in rural contexts.

Discussion: While space-derived tools can reduce rural disparities, their ethical use depends on design that empowers patients and providers. Autonomous systems must be transparent and culturally adapted. Equity requires targeted public investment and regulatory clarity.

Conclusion: Space medicine provides a high-tech model for delivering care where providers are scarce and distances vast. To fulfill the values of liberty, equality, and fraternity in European primary care, deployment of these tools must center on ethical governance, legal accountability, and human-centered design.NOVA

ID 476- Implementing community-oriented Basic Life Support training in primary health care

Sofia NEVES, Filipa BRITO

Usf Ribeirinha, Barreiro, Portugal

Context: Family continuity implies thi mplies the same clinician caring for multiple family members, often across generations. same clinician caring for multiple family members, often across generations.

Methods: A previously healthy 13-year-old girl with regular menstrual cycles began experiencing left abdominal pain radiating to the left leg in June, without other associated symptoms. Due to the severity of the pain, her mother took her to the emergency room (ER) on two different occasions, where an abdominal X-ray was performed and she was medicated with an enema, with slight improvement. During the second ER visit, a paediatric consultation was scheduled. At a routine surveillance appointment with her family doctor, the mother expressed concern that the pain persisted and remained severe.

On examination, a palpable hard mass was identified in the hypogastrium. An abdominal ultrasound was requested and a follow-up appointment was arranged. The paediatric consultation took place in mid-September but had to be postponed to January because the ultrasound requested by the family doctor had not yet been performed. The ultrasound revealed a large cystic formation occupying the hypogastrium (14 cm × 7.4 cm × 11 cm) with thin septations and a small amount of peri-lesional free fluid. The family doctor immediately referred the patient to the ER, where an urgent paediatric surgery consultation was arranged. Additional tests suggested a bilateral ovarian teratoma, leading to surgery.

Originality: This case highlights the importance of continuity of care and how essential it is to know one's patients and to value family concerns.

Lessons learned and future implications: Ultimately, this case illustrates how longitudinal, relationship-based care enables family doctors to interpret symptoms within a broader clinical and personal context, rather than as isolated episodes

Discussion: The longstanding relationship between the family doctor and both mother and daughter allowed recognition of the significance of persistent symptoms and the need for timely investigation—contrasting with the ER approach, which focused primarily on short-term symptom relief.

Conclusion: By recognising patterns, valuing parental concerns and prioritising appropriate investigation, family medicine plays a crucial role in early diagnosis and intervention. This continuity also sustains trust, ensuring that families feel heard, understood and supported throughout the course of care.

ID 1693- Implementing Data-Driven Tools in General Practice; an interactive and perspective workshop from the Global PBRN Initiative within WONCA Working Party on Research (WPR)

Karin HEK, Liselore CARIOT, Mariska SCHEFFER, Cathrien KAGER, Lotte RAMERMAN

Nivel, Utrecht, Pays-Bas

Context: Approximately 15% of the Dutch population visits a general practitioner at out-of-hours general practice services (OOH-GPS) at least once per year. Antibiotics are among the most frequently prescribed medications at these services, with considerable variation between locations, suggesting room for improvement. Inappropriate or excessive prescribing can contribute to antibiotic resistance, increased side effects, higher healthcare costs, and negative environmental impacts.

Objectives: This study aimed to develop a national learning community and provide an overview of interventions to promote appropriate antibiotic prescribing in OOH-GPS.

Methods: We collected data on existing interventions through a survey amongst Dutch OOH-GPS and an international literature review. Next, we identified facilitators and barriers to implementation, using the RE-AIM framework, from an organizational perspective via a learning community session with Dutch OOH-GPS and from the perspectives of healthcare providers and patients through interviews and surveys.

Results: The literature review indicated that interventions primarily focus on physician education (e.g., webinars, e-learnings), patient education (e.g., booklets, infographics), and communication strategies (e.g., guideline-based instructions). Audit and feedback strategies, such as personalized feedback and prescribing comparisons, are also often applied. Successful implementation was facilitated by early and voluntary stakeholder involvement, tailored materials, and patient education, while key barriers include varying motivation, practical constraints, and resistance to change. 17 OOH-GPS filled out the

survey. Decision support and diagnostics were the most often used interventions. Stakeholder involvement was most often mentioned as facilitator and time pressure as barrier.

Discussion: Knowledge exchange in learning community sessions enhances the yield of data collection beyond literature reviews, surveys and interviews.

Conclusion: The learning community session showed the potential benefits of cross regional knowledge exchange to enhance sustainable antibiotic prescribing practices in OOH-PCS. An overview of interventions to promote appropriate antibiotics prescribing at OOH-PCS was created that can be used to discuss AMR interventions at OOH-PCS within the own country.

ID 2127- Implementing Intelligent Automation in Primary Care: Transferable Principles for Reducing Administrative Burden

Sofia NEVES, Ricardo MARQUES, Maria GAMENHAS, André NEGRÃO, Teresa CARMONA

Usf Ribeirinha, Barreiro, Portugal

Context: Vaccine hesitancy remains a significant barrier to achieving optimal immunization coverage and public health outcomes. Even though vaccination might be a public heath workers'concern in many countries, general practitioners and family physicians are in a privileged position to play a key role in vaccination due to their holistic view of the patient and the strenght of doctor-patient relationship.

Objectives: This workshop aims to equip health professionals with practical knowledge and strategies to identify, understand, and address vaccine hesitancy among patients. Participants will explore the psychological, cultural, and social factors influencing vaccine acceptance, review evidence-based communication techniques, and engage in interactive case discussions to practice patient-centered approaches.

Teaching method and workshop: We will train the improvement of communication skills, how to address misinformation and use the doctor-patient relationship to build trust and individualize the approach to each person. Motivation interviewing will be the main communication technique ex

Expected outcomes: By the end of the session, attendees will be better prepared to foster trust, provide accurate information, and support informed decision-making regarding vaccinations.

Conclusion: The workshop ultimately seeks to strengthen the role of health professionals as advocates for immunization and promoters of community health.

(8) Cas Nou Barris-Barcelona (spain), Barcelona, Espagne

Context: Postpartum mental health conditions are highly prevalent: baby blues affect up to 50–80% of new mothers, postpartum depression (PPD) 10–20%, postpartum anxiety disorders 15–21%. Postpartum psychosis, though rare (0.1–0.26%), requires urgent intervention. While baby blues resolve spontaneously, untreated PPD has major consequences for maternal functioning, infant

development and the wellbeing of the entire family. Psychiatric history, low social support, sleep disruption, stressful life events are established risk factors. Importantly, cessation of breastfeeding is not an effective treatment for PPD or postpartum psychosis and should be considered only as a last resort. Strengthening primary care capacity in early detection, supportive communication and timely intervention can significantly reduce the burden of postpartum mental health disorders.

Objectives: Perform accurate, efficient screening using validated primary-care tools. • Differentiate baby blues, PPD, postpartum anxiety, postpartum psychosis by symptoms, onset and course. • Implement brief, evidence-informed psychosocial strategies feasible in routine consultations. • Select safe, breastfeeding-compatible pharmacotherapy. • Strengthen understanding of breastfeeding benefits to support WHO-recommended duration.

Teaching method and workshop: The workshop combines concise expert input with active, gamified learning. A short Kahoot quiz introduces key concepts and misconceptions. Participants work through a stepwise clinical vignette to practise screening + differential diagnosis. Small groups

Expected outcomes: Develope a reproducible screening workflow, increased confidence in supporting women with postpartum mood disorders, practical tools for delivering brief psychosocial interventions.Selecting breastfeeding-compatible treatment options. Strengthening compet

Conclusion: Integrating structured screening, supportive communication, evidence-based interventions into primary care is essential to improve outcomes for mothers, infants and families.

Corresponding author: Jana Krzyžánková, jana.krzyzankova@gmail.com

ID 513- Implementing the ABCDEF ICU Liberation Bundle to Shorten Delirium Duration in a Mechanically Ventilated Patient: A Practice-Based Reflection

Mayra SANAULLAH, Mary PRESTON, Ingrid WALLACE, Joanne SELWAY

University Of Buckingham., Milton Keynes, Royaume-Uni

Context: Primary care placements expose students to the communities they will serve, offering opportunities to engage with patients across the socioeconomic spectrum. Little is known whether the socioeconomic characteristics of patients seen by students, measured using postcode-linked Index of Multiple Deprivation (IMD) deciles, reflect the host practice population. Understanding this is important for promoting equitable and socially accountable medical education.

Objectives: To examine whether the deprivation status of patients seen by medical students during primary care placements aligns with the overall practice population.

Methods: A cross-sectional study included five practices hosting third-year medical students: three in higher IMD (less deprived) areas and two in lower IMD (more deprived) areas. Student consultations were extracted from EMIS and SystemOne. Patient IMD deciles were compared with practice-level IMD data from NHS Fingertips, an online platform providing UK healthcare statistics. Descriptive analysis assessed whether students were exposed to patients representative of their practice population.

Results: Across practices, the range of IMD deciles of patients seen fell in the same half of the scale as the practice average. In higher IMD practices (deciles ~9), students typically saw patients in deciles 5–10; in lower IMD practices (deciles ~2), patients ranged 1–5. Students saw more deprived patients than the practice average in higher IMD(median of 7.85 vs 9.3) areas and slightly less deprived patients in lower IMD areas(3.23 vs 2.5). Students encountered a broader range of deprivation than the practice average.

Discussion: Although student exposure does not exactly match practice averages, they experience a wider deprivation spectrum within the same relative range. Variation may result from appointment type, patient availability, or allocation practices. Recognising this broader exposure supports the development of socially accountable clinicians and can guide supervisors in targeting under-represented groups.

Conclusion: Deprivation representation in student consultations reflects the same relative half of deprivation as the host practice, but students encounter a broader range of IMD deciles than the average suggests. Awareness of this diversity is important for planning placements that promote equity and social accountability. Further research should compare students' patients with those seen by GPs to assess alignment with expected clinical workloads and ensure representative exposure.

ID 539- Improper communication's influence on people's lives and how to manage it

Robert BATES [(1)] , Jane RICKS [(2)], Dan RICKS [(2)]

(1) Brigham Young University, Provo, États-Unis
(2) Independent Researchers, Salt Lake City, États-Unis

Context: Colorectal cancer (CRC) is the second leading cause of cancer death in Europe, taking over 930,000 lives worldwide in 2020. Due to the benefits of screening for CRC, it is universally recommended. These recommendations are primarily based on studies in developed nations. Since the incidence of CRC increases with age and with GDP per capita, there is an increased burden of disease due to CRC in developed countries, we must acknowledge that in the poorest countries, people may not live long enough to develop CRC, nor have the resources for treatment if CRC is acquired, so screening may not be beneficial.

Objectives: The objective of this study is to look at a country's longevity, health care resources, and cost of screening for CRC, to identify when it is reasonable to begin CRC screening within a developing country.

Methods: We gathered existing international data on the age of diagnosis of CRC, the longevity in a country, the incidence of CRC as related to GDP per capita, and the health care resources available for a country. We correlated this data with the World Health Organization's recommendation that a screening test be less than 3 times a country's GDP to be cost-effective.

Results: There are many countries in sub-Saharan Africa and Asia where universal CRC screening may not yet be warranted. All European countries have a high enough GDP per capita and population longevity to benefit from CRC screening.

Discussion: Universal screening for CRC may not be practical for all countries. Implementation when the longevity and resources of the country merit widespread screening may be more feasible. We must be careful not to push for programs in developing countries too soon, nor wait too long to implement helpful strategies once they benefit from CRC screening.

Conclusion: Cancer screening is most valuable when a country has a significant burden of disease and has the resources to treat the disease for which they are screening. This study emphasizes the need to tailor healthcare programs to the needs of each community and nation.

(4) Center For Bioethics Research / Nova School Of Law Of University Nova Of Lisbon, Lisbon, Portugal

Context: Spirituality, understood as the pursuit of meaning, connection, and purpose, is increasingly recognised as a core dimension of patient-centred care. Despite its non-religious and deeply human character, it remains under-integrated in European primary and paediatric care, particularly in Portugal.

Objectives: To synthesise recent scientific literature on the role of spirituality in ethical primary and paediatric care across the lifespan, including neonatal, childhood, adult, and palliative contexts, with emphasis on the role of family physicians, paediatricians, neonatal clinicians, and family caregivers in Portugal and Europe.

Methods: A narrative literature review was conducted across peer-reviewed journals (2015–2025) using PubMed, Scopus, and ScienceDirect. Keywords included: “spiritual care,” “primary care,” “family medicine,” “paediatrics,” “neonatology,” “bioethics,” “palliative,” and “Portugal.” Preference was given to European, interdisciplinary, and clinical ethics sources.

Results: Studies reveal strong patient and family preference for spiritual inclusion in care, especially during chronic illness, end-of-life, and paediatric crises. Spiritual care is linked to better coping, well-being, and decision satisfaction. Family physicians, paediatricians, and neonatal clinicians often lack training or confidence, but are well positioned due to their continuity of care roles. Paediatric literature emphasises family-centred spiritual support, especially in neonatal intensive care and bereavement. Portuguese studies echo broader European findings: clinicians value spirituality ethically but lack structured support and training.

Discussion: Integrating spirituality into bioethical care supports holistic and dignified practice across all ages. Family physicians and paediatric professionals can use brief tools, referrals, or empathetic presence. European guidelines increasingly endorse spiritual care, yet practical gaps persist in training and system integration, especially in Southern Europe.

Conclusion: Spirituality is an ethically vital, evidence-supported component of lifespan care in both primary and paediatric contexts. Institutional and educational strategies are needed to equip European family physicians, paediatricians, and neonatal clinicians to address spiritual needs respectfully and competently throughout life.

(2) Detectair, Research And Development Organisation, Bratislava, Slovaquie
(3) University Hospital Bratislava, Bratislava, Slovaquie

Context: A general practitioner (GP) who cares for elderly patients discharged from hospital to a home or nursing home faces the challenges of healthcare-associated infections (HAIs). An antimicrobial dry fog disinfection (DFD is a new modality of multimodal infection control strategy.

Objectives: To assess the effectiveness of antimicrobial DFD disinfection in the open healthcare microenvironment of a long-term care department consists of 10 (2-3 bed) rooms, average of 252 patients hospitalized annually average of 21 days. Most of patients are discharged to home care and to nursing home.

Methods: We analysed the microbiological contamination of surfaces and air in patient rooms.

Results: I.We analysed the microbiological contamination of surfaces. Before the DFD application, we detected: Staphylococcus epidermidis, a potential cause of HAIs, Enterobacteriaceae and Pseudomonas

aeruginosa, clinically serious pathogens (urinary, respiratory tract and wound infections), Bacillus spp. and Micrococcus spp., a common part of the environment, but indicate general contamination. In one sample, Penicillium spp. was also present, indicates the presence of Mold. After the application of DFD, all tested surfaces were negative for pathogens such as Staphylococcus, aureus, Pseudomonas aeruginosa, Enterobacteriaceae or yeast. Only occasionally were detected Bacillus spp. and Micrococcus spp., which are considered non-pathogenic, environmental bacteria, naturally present in the environment. II.We analysed the microbiological contamination of air. Before disinfection, the total number of microorganisms reached 304 - 393 CFU/m3, which represents high environmental contamination. Molds were captured in the cut (118 – 142 Colony Forming Units(CFU)/ m3). Yeasts and Staphylococcus spp. were not detected before disinfection. After DFD the total number of microorganisms dropped to 73 – 102 CFU/m3. Molds were reduced to 53 – 73 CFU/ m3. Yeasts and Staphylococcus spp. were not detected even after disinfection. DFD reduced the microbial load of the air by 70-80%.

Discussion: The practice requires further studies in the future so that the effectiveness of DFD can be assessed more comprehensively

Conclusion: The use of DFD has the potential to significantly reduce the microbial burden as part of a comprehensive HAI prevention strategy in department predominantly caring of frail patients and then facilitate the work of GPs after discharge.

ID 890- Improving diabetes screening in a suburban polyclinic

Lucas ABREU CAVERSAN, Margarita SILVA DIERCKS, Lena AZEREDO DE LIMA, Fernanda MIRANDA SEIXAS EINLOFT, Scheila MAI, Laura MACHADO SCOTT, Deivid VIEIRA SILVEIRA, Rosa LEVANDOVSKI, Ângela PAVEGLIO TEIXEIRA FARIAS

Grupo Hospitalar Conceição (ghc), Porto Alegre, Brésil

Context: The demographic transition in many countries is highlighted by the accelerated aging of the population and the high prevalence of hypertension and type 2 diabetes mellitus (DM2). It is necessary that the care be guided by the Chronic Conditions Model (CCM), characterized by: vulnerability and cardiovascular risk stratification, comprehensive care by an interprofessional team, person-centered approach, evidence-based practices, supported self-care, and a monitoring and evaluation system.

Methods: The Interprofessional Working Group for the Care of People with Chronic Conditions of the XXX developed the Hypertension and DM2 Care Guide to support decision-making in Primary Health Care (PHC), improve care, and subsidize a continuing education process to promote the CCM. The content was defined based on updated guidelines and reviewed by PHC specialists. The guide was organized using an objective layout, based on diagrams, flowcharts, and mind maps for rapid clinical decision-making. It consists of six sections: CCM - Pillars of care in hypertension and DM2; Technologies and Support Tools (e.g., Motivational Interviewing); Lifestyle Changes; Care for People with Type 2 Diabetes; Care for People with Hypertension.

Originality: The Guide adapts the latest evidences to the reality and public health resources of the local population.

Lessons learned and future implications: The Guide enhances the practical learning and can be used for quick reference by PHC professionals during their clinical practice and for the development of continuing education programs for these same professionals. It can be adapted to other health systems according to their organizational structure of professionals and available resources.

Discussion: Facing the overload of PHC with acute demands, high staff turnover and a focus on productivity, consolidating the CCM and the good care practices represents a political and educational challenge. The Guide and the continuing educations developed from it emerge as strategies capable of promoting

effective and sustainable improvements in the daily routine of PHC.

Conclusion: Implementation of the Guide, integrated with continuing education, encourages the adoption of evidence-based practices, the consolidation of the CCM, and fosters the protagonism of PHC teams. The Guide stands out as a relevant and strategic tool to improve the quality of health care for people with hypertension and DM2 in PHC.

ID 362- Improving Humanized Healthcare for Adult Patients in Primary Care: Insights from Clinical Practice

Hasara KULATUNGA

Senior Registrar In Family Medicine, Colombo, Sri lanka

Context: A 68-year-old man with long-standing, poorly controlled hypertension who had defaulted regular medication and intermittently relied on Ayurvedic therapy, presented with markedly elevated blood pressure during a consultation for trigger finger of the right fourth digit. Despite minimal symptoms, evaluation revealed end-organ involvement. The patient also carried significant caregiver burden as the sole caretaker of his chronically ill wife. The case occurred within an efficient government health system, which provides free, equitable care in a resource-limited setting and enabled an urgent cardiology referral to be completed within two days.

Methods: Assessment included repeated blood pressure measurements, cardiovascular examination, ECG, laboratory evaluation, and abdominal ultrasound. Initial treatment comprised Losartan, Amlodipine, and Atorvastatin, followed by urgent cardiology review. Subsequent optimisation added Spironolactone and Empagliflozin with structured lifestyle counselling. Trigger finger intervention was postponed until adequate blood pressure control was achieved.

Originality: This case demonstrates how a potentially life-threatening condition may be detected incidentally during consultation for a minor musculoskeletal complaint. It highlights the necessity of balancing patient-reported priorities with objective clinical urgency while addressing the influence of caregiving responsibilities and alternative-medicine practices on treatment adherence. It also exemplifies how a strong public health system can deliver timely specialist care even in low-resource settings.

Lessons learned and future implications: Recognition of hypertensive target organ damage is crucial even in minimally symptomatic patients. Sustainable management requires culturally sensitive counselling, simplified medication plans, and follow-up strategies that consider caregiver strain. Strengthening primary-specialist coordination and health-system navigation support may further improve outcomes.

Discussion: Severe hypertension with concentric LVH and diastolic dysfunction required aggressive therapy consistent with current guidelines. The patient's inconsistent adherence and external stressors necessitated personalised, realistic care planning to ensure continuity and safety.

Conclusion: This case illustrates how comprehensive primary care can uncover severe hypertension during unrelated presentations and leverage a functional public health system to deliver timely specialist intervention, ultimately improving patient safety and long-term cardiovascular risk. Ongoing follow-up will prioritise medication adherence, monitoring for complications, and supporting his caregiving responsibilities to ensure sustained blood pressure control and improved quality of life over the coming months ahead.

(1) Family Medicine Resident, Madrid, Espagne
(2) Family Medicine Attending, Madrid, Espagne

Context: First consult in the emergency department (ED), with resolution in Primary Healthcare.

Methods: Woman, 88 years old was evaluated for intermittent episodes of macroscopic hematuria associated with dysuria, without fever or any other symptoms. On initial assessment in the ED the patient was hemodynamically stable, afebrile and with an unremarkable physical examination. Blood tests revealed no significant abnormalities; urinary sediment showed haematuria and leukocyturia. The diagnosis of self-limited hematuria in the context of a probable urinary tract infection (UTI) was made, the patient received a single dose of fosfomycin. The patient was seen then in Primary Healthcare reporting persistent dysuria. On both visits hematuria persisted in the urinary sediment. Given the ongoing abnormality, an abdominal point of care ultrasound (POCUS) was performed, which revealed a polypoid appearing intravesical lesion. Urinary cytology was requested and it showed suspicious results for urothelial adenocarcinoma. The patient was referred urgently to Urology for further work-up.

Originality: POCUS is an emerging tool in Primary Healthcare. This case exemplifies how integration into routine practice can enable earlier detection of clinically significant urological pathology that otherwise would be identified at later stages.

Lessons learned and future implications: This case underlines the importance of proactive follow-up in primary care, as well as the diagnostic value added by POCUS. This case also emphasizes the need for close surveillance of persistent symptoms that may initially be attributed to common conditions such as UTI (1). It also highlights the importance of expanding POCUS training in Primary Healthcare and establishing clear care pathways to optimize it use, strengthen the coordination with specialists, and facilitate earlier diagnosis (2).

Discussion: Persistent hematuria can conceal significant pathology. In this case, POCUS permitted early visualization of a suspicious bladder lesion, which made possible the request of other tests and a referral to Urology.

Conclusion: Access to diagnostic tools such as POCUS in the clinic enhances the problem solving capacity of primary care. Their integration into routine practice modernizes the role of the Family Medicine physician, increases opportunities for early diagnosis and improves overall patient care.

Context: Women in prostitution face heightened exposure to drugs and chemical vulnerability, which increase health risks and complicate access to care. Many times, prostitution is not a choice at all, but a survival method or a forced necessity. Primary care physicians often encounter these patients, making early identification and harm reduction crucial. Awareness of the intersection between substance use and sex work enables physicians to provide compassionate, effective care, improve health outcomes, and address broader public health challenges.

Objectives: The participants will increase their level of awareness and be able to recognize the unique health risks and chemical vulnerabilities faced by women involved in prostitution. They will learn to identify common patterns of substance use within this population and understand the broader social, psychological, and public health implications. Participants will also learn to use basic, nonjudgmental communication tools that support trauma-informed, patient-centered engagement.

Teaching method and workshop: The workshop will employ an interactive format featuring brief interactive presentations and a roundtable discussion on the key topics using real-case examples, followed by a reflection and a Q&A session. 5 min — Introduction 30 min — Roundtable discuss

Expected outcomes: The participants will develop awareness of the unique challenges and vulnerabilities faced by women involved in prostitution. They will improve their ability to recognize substance use and chemical vulnerabilities in this population. Physicians will be be

Conclusion: We live in a world where mobility, vulnerability, and limited safe work push many women into extreme survival methods. Addressing drug-related vulnerabilities in women involved in prostitution is essential for effective primary care. This training aims to open the eyes to the realities these women face, provide new context, and leave physicians with a heightened level of awareness that informs and improves their practice.

Mongi Slim University Hospital, Tunis, Tunisie

Context: Cardiac arrhythmias and conduction disorders are life-threatening emergencies, especially in older adults. Early recognition and rapid management are essential, relying on an initial evaluation that identifies patients at highest risk of adverse outcomes.

Objectives: This study aimed to determine the predictors of in-hospital mortality among patients aged 65 years and older admitted to the emergency department for arrhythmias and/or conduction disorders.

Methods: A two-year prospective, descriptive, and analytical study was conducted. It included all patients aged ≥65 years managed in the emergency department for a documented cardiac rhythm or conduction disorder. Clinical presentation, comorbidities, therapeutic interventions, and in-hospital outcomes were collected. Univariate and multivariate logistic regression analyses were performed to identify factors associated with in-hospital mortality.

Results: A total of 102 patients were enrolled, with a mean age of 76±7 years and a sex ratio of 0.75. The most prevalent comorbidities were arterial hypertension(78.4%), previously known arrhythmias(48%), coronary artery disease(37.3%), heart failure(16.7%), and valvular heart disease(15.7%). The leading presenting symptoms included dyspnea(37.2%), fatigue(24.4%), chest pain(16.5%), palpitations(15.2%), and impaired consciousness (7.3%). Atrial fibrillation was the most frequently recorded arrhythmia(67.6%). The most common conduction disorders were atrioventricular blocks(12.7%) and sinoatrial blocks(6%). Congestive heart failure was present at admission in 20.7% of cases. The overall in-hospital mortality rate was 10%.In univariate analysis, mortality was associated with age ≥85years(OR=4.09;p<0.02), a history of ischemic stroke(OR=2.73;p<0.001), Glasgow Coma Scale<15 on admission(OR=5.13;p<0.01), and third-degree atrioventricular block(OR=2.17;p< 0.006). In multivariate analysis, two independent predictors of in-hospital mortality were identified:age≥85years(adjusted OR=7.07;p=0.008) and a history of ischemic stroke (adjusted OR=2.47;p=0.001).

Discussion: Our findings are consistent with those of Gaur et al.[1], who reported that a

history of cerebrovascular disease predicts atrial fibrillation recurrence and poor overall prognosis. Advanced age (≥85years) also emerged as a strong mortality predictor, likely due to age-related structural and electrical cardiac remodeling and the accumulation of competing comorbidities. Similar conclusions were highlighted by Curtis et al.[2], who emphasized the impact of these age-related changes on disease evolution and therapeutic response.

Conclusion: Arrhythmias and conduction disorders in older adults represent a major management challenge in emergency settings. Early identification of high-risk patients may improve triage and initial management thus ultimately reducing mortality.

Jesús Francisco ARZÚA MOYA [(1)] , María ALCARAZ PÉREZ [(2)]

(1) Sergas, Boiro, Espagne
(2) Sergas, Santiago De Compostela, Espagne

Context: Infantile Sweet syndrome is a rare neutrophilic dermatosis that may present with polymorphic skin lesions, fever, and systemic symptoms. Because its manifestations overlap with common pediatric diagnoses, primary care plays a crucial role in early suspicion, referral, and follow-up.

Methods: A 5-year-old boy presented with recurrent episodes of painful vesiculobullous lesions on the face, ears, hands, and forearms over several months. Initial episodes were interpreted as insect bites or viral exanthems. Later, during a febrile episode, he developed a widespread urticariform rash affecting palms, soles, genital area, and face. Prior clinical assessments and treatments produced partial or no improvement. A skin biopsy revealed subepidermal blistering with neutrophilic and eosinophilic infiltrates, consistent with Sweet syndrome. Serology showed Mycoplasma IgM positivity and ANA 1:160 granular pattern. Systemic corticosteroids resulted in rapid improvement. The case required repeated primary care reviews to monitor symptom recurrence, treatment response, and potential complications.

Originality: Infantile Sweet syndrome is uncommon and often under-recognised in its vesiculobullous form. Literature predominantly describes papular or plaque-type lesions, making this polymorphic presentation unusual. The case highlights the diagnostic challenge when recurrent lesions mimic infectious, allergic, or autoimmune diseases. Its contribution lies in demonstrating a rare pediatric presentation detected through longitudinal primary care follow-up.

Lessons learned and future implications: Primary care physicians should consider neutrophilic dermatoses in recurrent vesiculobullous pediatric eruptions, especially when initial treatments fail. This case illustrates the value of early biopsy and multidisciplinary coordination. Increasing awareness may reduce diagnostic delays, unnecessary antibiotic use, and caregiver distress. Future practice should include systematic review of recurrent dermatologic presentations and early referral for histopathology.

Discussion: The diagnostic complexity of this case reflects the wide differential for pediatric vesiculobullous lesions, including erythema multiforme, vasculitis, childhood lupus, and bullous pemphigoid. Primary care continuity allowed recognition of a pattern of recurrence, prompting referral for biopsy. Evidence supports systemic corticosteroids as first-line treatment in pediatric Sweet syndrome. The case shows how early identification improves outcomes and avoids prolonged morbidity.

Conclusion: This case emphasizes the importance of primary care in identifying rare dermatologic conditions through continuity, pattern recognition, and timely referral. Awareness of atypical presentations of infantile Sweet syndrome can improve diagnostic accuracy and reduce unnecessary treatments.

(1) Usf Alfa Beja-Ulsba, Beja, Portugal
(2) Usf Planicie-Ulsca, Évora, Portugal

Context: “Coração fora do peito” is a popular Portuguese expression that literally means “heart outside the chest”, but in this case it does not refer to a figure of speech. An 86-year-old male patient presented to his family physician due to pacemaker (PM) exteriorization with one week of evolution, without pain or fever.

Methods: The patient has a history of long-standing arterial hypertension with target organ damage, dyslipidemia, stage G4 A2 chronic kidney disease, hypertensive heart disease with mild congestive heart failure, and has had a dual-chamber permanent pacemaker since 2020 due to symptomatic bradycardia. Physical examination revealed dehiscence of the PM pocket with partial exteriorization and peripheral necrosis, without signs of systemic infection. He was referred to the hospital emergency department, where laboratory tests and blood cultures were negative. The patient was admitted to the cardiology ward for monitoring and pacemaker replacement, starting antibiotic therapy with ciprofloxacin.

Originality: The use of pacemakers has increased significantly in recent decades, reflecting an aging population and greater survival of patients with cardiac disease. Erosion or exteriorization of the generator is a rare complication, with reported rates of 1–7%, depending on individual risk factors, multiple reinterventions, and center experience. This case illustrates a relatively uncommon clinical presentation and emphasizes the need for early surveillance, identification of predisposing factors, and multidisciplinary intervention.

Lessons learned and future implications: This case highlights the importance of monitoring implanted devices, recognizing early signs of exteriorization, and planning timely surgical intervention. The experience suggests that future practices could include systematic assessment of subcutaneous tissue, preventive strategies for generator positioning, and individualized follow-up protocols for elderly patients or those with complex comorbidities.

Discussion: The literature shows that although this complication is rare, it can have a significant impact on the patient, conditioning a potencial life-threatening situation, requiring a multidisciplinary approach. Prevention of erosion involves proper implant planning and continuous monitoring, with early interventions to minimize risks.

Conclusion: This case underlines the clinical relevance of pacemaker exteriorization, reinforcing the need for preventive strategies, careful surveillance, and coordinated management. It provides practical lessons applicable to similar contexts, contributing to improved patient safety and care.

Context: Food noise refers to obsessive and intrusive thoughts about food and poses a significant challenge for individuals striving to manage their weight. This cognitive and emotional distraction can lead to overeating and hindering of a healthy lifestyle implementation, including weight management efforts. The effectiveness of semaglutide, a GLP-1 receptor agonist, in promoting weight reduction in obese patients

is well established. However, studies evaluating its impact on food noise symptoms and their effects on mental health are lacking.

Objectives: This survey aimed to gain insights into the potential positive change in the impact of food noise and mental wellbeing before and after initiating semaglutide.

Methods: A mobile survey was completed in May 2025 by 550 verified individuals, currently using semaglutide for weight management, residing in various locations throughout the United States. The survey consisted of 22 questions, including a previously validated Food Noise Questionnaire (FNQ) and a self-reported demographic and mental wellbeing survey. The 550 respondents provided answers to all questions.

Results: Mean age was 53 (SD 10.8); of 550 respondents, 473 (86%) were female, 432 (79%) Caucasian, 350 (64%) weighed ≥92 kg at semaglutide start, and 447 (81%) had used it ≥4 months. Food-noise questionnaire (FNQ) scores fell substantially from before to during treatment: constant thoughts about food −46% (95% CI 41–51), uncontrollable thoughts −37% (33–42), time spent thinking −48% (44–52), negative impact −40% (35–44), and distraction from daily activities −32% (28–37). Also, 352 (64%) reported better mental health, 417 (76%) greater self-confidence, and 438 (80%) healthier habits.

Discussion: Overall, most respondents, 457 individuals (83%), expressed satisfaction with their semaglutide treatment.

Conclusion: The present findings indicate semaglutide may not only facilitate weight management but also alleviate cognitive distractions related to food and enhance the mental well-being of individuals living with obesity. Further research is warranted to confirm these results.

Context: Semaglutide (sema) treatment results in substantial weight loss in adults with overweight and obesity.

Objectives: In this analysis we investigated the changes in body composition and muscle strength as a result of sema-induced weight loss.

Methods: In this phase 3b RCT, adults with BMI ≥30 kg/m2 without T2D were randomized 5:1:1 to sema 7.2 mg, sema 2.4 mg, or placebo for 72 weeks with lifestyle intervention. A MRI subpopulation had body composition measured from knees to T9: total adipose tissue (AT: subcutaneous + visceral [VAT]) and lean tissue (LT). Outcomes at week 72 included % body-weight change, absolute (L) and % changes in AT, VAT, LT, and AT:LT ratio. Volumes were converted to mass using densities (AT 0.92 kg/L; LT 1.1 kg/L). Muscle strength was assessed by a 30-s sit-to-stand test. Data are from MRI participants during the in-trial period, pooled across sema doses under the treatment-policy estimand.

Results: Among MRI-scanned patients (sema n=49; pbo n=6), mean baseline weight was 110.8 kg. Baseline tissue volumes were—sema vs pbo: AT 42.9 L vs 47.1 L; VAT 5.4 L vs 5.1 L; LT 23.8 L vs 24.5 L. Sema produced greater %

weight loss versus pbo (ETD −16.5% [95% CI −26.3, −6.8]; p=0.0009), larger reductions in total AT (ETD −11.1 L [−16.5, −5.7]; p<0.001) and VAT (ETD −1.5 L [−2.9, −0.1]; p=0.042). LT fell in the sema group but not significantly versus pbo (ETD −1.7 L [−4.0, 0.7]; p=0.164). Estimated mass losses were 10.2 kg (AT), 1.4 kg (VAT), and 1.9 kg (LT); 84.5% of weight lost was from AT and 15.5% from lean mass. Percent changes in AT, VAT, and LT were similar, and AT:LT ratio improved more with sema (1.80→1.35) than pbo (1.93→1.85).

Discussion: There were no differences between sema and pbo in the change from baseline in number of repetitions performed in the sit-to-stand test (ETD −0.1 [−3.6, 3.4]; p=0.97).

Conclusion: Weight loss associated with sema treatment was accompanied by clinically important reductions in total AT and VAT, with a small fraction of weight lost from LT, alongside preserved sit-to-stand capability.

ID 239- Increasing risk of lung cancer among people living with HIV: a meta-analysis

Shengyang David ZHANG, Lay Hoon GOH

National University Of Singapore, Yong Loo Lin School Of Medicine, Singapore, Singapour

Context: Falls cause significant morbidity among Singaporean seniors. In low-income populations lacking access to sensory aids, the contribution of undetected hearing and vision impairments to fall risk requires investigation.

Objectives: To investigate associations between vision/hearing screening outcomes and self-reported falls among rental-flat seniors, adjusting for age, gender, and dizziness.

Methods: In October 2025, 147 Toa Payoh rental-flat residents (mean age:64.0±10.8) underwent surveys, Snellen vision testing, and audiometry (40dBHL). Multivariable logistic regression (N=116) assessed associations between screening failure ("impairment") and self-reported falls, adjusting for age, gender, and dizziness.

Results: 14 (9.5%) of 147 participants reported ≥1 fall in the preceding year. 6(4.1%) failed vision screening. 16(10.9%) failed hearing screening. 37.5% (6/16) of those with hearing impairment reported falls compared to only 6.1% (8/131) of those with normal hearing (OR=6.90,95% CI[1.94-24.26],p=0.0023). After adjusting for age, gender, and dizziness in the multivariate model, hearing impairment is still a significant independent predictor of falls (adjusted OR=6.10,95% CI[1.49-26.15], p=0.0118). Females demonstrate increased fall risk (OR=5.53, 95% CI [1.42-29.87], p=0.0238). Age showed a trend toward significance (OR=1.06/year,95% CI[0.997-1.14],p=0.077). Dizziness did not independently predict falls after accounting for sensory impairment (OR=1.09,95% CI[0.21-4.55],p=0.905), suggesting sensory impairment as the underlying cause. No association between vision impairment and falls due to the small number of vision failures (n=6), also possibly due to vision failures being more obvious and likely to be corrected.

Discussion: Uncorrected hearing impairment is a potent, modifiable risk factor in this demographic, contributing to falls via reduced environmental hazard awareness, cognitive load redistribution and vestibular dysfunction. The 10.9% screening failure rate highlights financial and psychosocial access gaps. Addressing hearing deficits offers substantial healthcare savings compared to the high costs of treating hip fractures. The gap in accessing hearing aids, may be due to financial barriers, or psychosocial barriers (believing hearing loss is normal). The strong association for falls in women (OR=5.53) may be due to factors, such as bone density differences, higher baseline frailty, or a greater willingness to report falls.

Conclusion: Routine community-based hearing screening is a vital, cost-effective fall prevention strategy. Interventions should prioritize subsidized hearing aids and targeted education to improve adherence and reduce fall-associated morbidity in vulnerable elderly populations.

Context: Metabolic dysfunction–associated steatotic liver disease (MASLD) is now one of the most common chronic liver conditions and is increasingly encountered in primary care. Family physicians play a pivotal role in early recognition, comprehensive metabolic assessment, lifestyle counselling, and follow-up. Because MASLD is deeply linked with obesity, diabetes, dyslipidemia, physical inactivity, and dietary patterns, its management requires a holistic approach that extends beyond liver health. This workshop provides practical, evidence-based tools to support clinicians in diagnosing MASLD, initiating risk stratification, and empowering patients toward sustainable lifestyle changes. This workshop is a collaboration between the Lifestyle Medicine SIG of WONCA Europe and the European Society for Primary Care Gastroenterology (ESPCG)

Objectives: To present the clinical spectrum of MASLD and practical approaches for risk stratification. To provide evidence-based strategies for nutrition, weight reduction, and physical activity in MASLD prevention and treatment. To introduce behavioural tools that support patient motivation and lasting lifestyle change. To review current and emerging pharmacologic and multidisciplinary options. To equip participants with pragmatic strategies that can be implemented immediately in daily practice.

Teaching method and workshop: Introduction (0–5 min): Why MASLD matters in primary care; epidemiology and metabolic context. Topic 1 (5–15 min): Clinical spectrum, red flags, interpreting liver enzymes, and using FIB-4 as a risk-stratification tool. Topic 2 (15–30 min): Lifestyle modi

Expected outcomes: Participants will be able to identify MASLD in primary care, apply non-invasive risk-stratification methods, deliver focused lifestyle and physical-activity guidance, use behavioural-change techniques, and understand when to escalate care or refer.

Conclusion: MASLD management begins in primary care. By integrating early recognition, lifestyle counselling, behavioural strategies, and coordinated care, family physicians can significantly improve long-term outcomes and empower patients toward healthier, sustainable change. ID 1253- Infantile Sweet Syndrome Presenting with Recurrent Vesiculobullous Lesions: The Role of Primary Care in Diagnosing Rare Dermatologic Conditions

Selima KTARI, Anthelme KOUAKOU, Nada ZERAMDINI, Alaeddine BEN MRAD, Zied ELLOUMI

Jean Leclaire, Sarlat La Canéda, France

Context: Chronic headaches are a frequent presentation in general practice and are usually benign, but atypical or refractory forms may conceal a serious intracranial disorder. Diagnostic difficulty increases when initial investigations are non-contributive or when MRI is contraindicated. This case illustrates such a challenge: progressively worsening headaches with transient neurological symptoms ultimately revealing a periaqueductal tumor responsible for obstructive hydrocephalus.

Methods: A 64-year-old man presented with two months of fluctuating but disabling fronto-occipital headaches, intermittently associated with visual blurring and right upper-limb myoclonus. Symptoms progressed to include nausea, vomiting, falls, and limb tremor. Initial laboratory work-up, ENT evaluation showing sphenoiditis (treated without effect), and three

cerebral CT angiographies were non-contributive. MRI could not be performed due to a metallic mandibular foreign body. The onset of transient malaise and pseudo-epileptic episodes prompted an EEG, which was normal. Ongoing clinical deterioration led to a lumbar puncture (LP), which provided immediate relief, suggesting intracranial hypertension. Cerebrospinal fluid analysis revealed markedly elevated protein (6 g/L), compatible with Froin's syndrome. This key finding prompted a meticulous re-evaluation of prior CT scans, revealing a small periaqueductal–pineal lesion obstructing CSF flow. The patient underwent endoscopic ventriculocisternostomy, biopsy, and placement of a ventriculo-cardiac shunt. Histology confirmed an anaplastic diffuse grade III glioma, followed by radio-chemotherapy.

Originality: This case is notable for its atypical presentation of obstructive hydrocephalus with fluctuating headaches, myoclonus, and pseudo-epileptic episodes. Diagnostic difficulty was compounded by non-contributive imaging and the impossibility of MRI. The LP,rarely central in chronic headache assessment,proved decisive by revealing Froin's syndrome.

Lessons learned and future implications: Atypical chronic headaches with neurological fluctuations require repeated clinical assessment and early specialist involvement. Lumbar puncture may be essential when headaches remain unexplained.

Discussion: Secondary headaches are challenging to diagnose when early investigations are normal. In this case, the combination of progressive headaches, transient neurological episodes, and immediate improvement after LP strongly pointed toward obstructive hydrocephalus. This case underscores the importance of revisiting radiological studies when clinical evolution is atypical, and highlights the diagnostic value of LP in selected situations.

Conclusion: Refractory headaches with transient neurological signs should prompt suspicion of secondary causes, including obstructive hydrocephalus and periaqueductal tumors.

ID 798- Inflammaging Risk Score (IRS): Detecting Early Biological Aging in Primary Care

Çiğdem DELICE SEZGIN, Vildan MEVSIM

Dokuz Eylül University Faculty Of Medicine, Department Of Family Medicine, Izmir, Türkiye

Context: In primary care, universal newborn hearing screening is a key preventive service that allows early detection of hearing loss, even in infants without risk factors. Early identification and prompt referral are essential for optimal language, cognitive, and long-term outcomes. This case report outlines the evaluation and coordinated management of a term newborn diagnosed with bilateral profound hearing loss during routine screening at a family health center.

Methods: A female infant was brought for a routine newborn exam. She was born at 37+5 weeks via uncomplicated vaginal delivery (3100 g) to a healthy 27-year-old mother, with no perinatal risk factors for hearing loss. Physical exam, including external ear anatomy, was normal. Otoacoustic emission (OAE) screening showed bilateral REFER on day 1 and day 7, leading to referral to a tertiary audiology center. At 3 weeks auditory brainstem response (ABR) revealed no detectable waves up to 90 dB bilaterally, consistent with profound sensorineural hearing loss. MRI/CT showed normal inner ear and auditory nerve anatomy. Genetic testing identified a homozygous GJB2 35delG mutation. The family physician coordinated multidisciplinary follow-up, parental counseling and early referral for cochlear implant evaluation and auditory-verbal therapy.

Originality: This case is notable because a full-term, low-risk newborn was found to have profound bilateral hearing loss solely through routine screening, highlighting the often-hidden burden of genetic causes in clinically low-risk infants.

Lessons learned and future implications: This experience underscores the importance of adhering to the "1-3-6 rule" in primary care.

Consistent screening, timely re-testing, early referral, and coordinated multidisciplinary communication are critical. Integrating stronger genetic counseling pathways within family medicine may further improve care.

Discussion: This case shows that profound hearing loss can occur even in the absence of risk factors, emphasizing the need for repeat screening, timely referral, and adherence to the 1-3-6 guideline in primary care to ensure early intervention and optimal outcomes.

Conclusion: Primary care plays a key role in detecting severe hearing loss in asymptomatic newborns. Early identification enables timely intervention and improves long-term speech and language outcomes.

(2) Mollet's Hospital, Mollet Del Vallès, Espagne

Context: Introduction: Excessive bureaucracy in primary care can lead to dissatisfaction among patients and healthcare professionals, reducing the efficiency and quality of care. This study evaluates the impact of a debureaucratization intervention in primary care.

Objectives: The main objective of the study is to assess the impact of a debureaucratization intervention in primary care on the efficiency and quality of care. Specifics objectives: - Improve care efficiency, measured by the number of patients seen per hour. - Reduce the time spent on administrative tasks. - Evaluate the effectiveness of assigning a coordinator, a physician, and administrative staff to handle bureaucratic visits

Methods: - A de-bureaucratization program was implemented by studying the medical visit schedules of 8 primary care physicians. - A daily coordinating physician who reviews schedules and handles bureaucratic visits (for example, lab results, electronic prescriptions, duplicate appointments). - Simplification of administrative processes. - Implementation of information and communication technologies (ICT). - Staff training in time management and task prioritization.

Results: The data collected over one month were compared with data from the previous month, working with the same professionals to avoid interprofessional variability. The intervention reduced administrative time by 30% and increased care efficiency by 20% (measured by patients seen per hour). The coordinating physician resolved an average of 25 bureaucratic visits daily, allowing doctors to focus on clinical care.

Discussion: The positive results of the study can be attributed to several factors: - Assignment of a coordinating doctor. - Assigning competent administrative staff. - Use of information and communication technologies.

Conclusion: Debureaucratization in primary care is an effective strategy to improve efficiency and the quality of care. Assigning a coordinating doctor with administrative support has been crucial for implementing and maintaining the debureaucratization program.

(1) Université De Montréal, Montréal, Canada
(2) Centre De Recherche Du Centre Hospitalier De L'université De Montréal, Montréal, Canada

Context: The Réseau de recherche en soins primaires de l'Université de Montréal (RRSPUM) is a research network created to strengthen collaboration between researchers and the 21 university family medicine groups (GMFUs) to produce knowledge applicable to

primary care. However, projects submitted to GMFUs are not always feasible within their clinical realities or aligned with their priorities. To address this issue, the RRSPUM sought to develop a structured tool to better assess the relevance and feasibility of proposed projects.

Objectives: To describe (1) the process used to develop an assessment grid for evaluating the relevance and feasibility of research projects submitted to GMFUs, and (2) the lessons learned from consulting partner researchers to refine this grid.

Methods: Building on scientific literature and field experience, two research facilitators and one patient partner jointly developed an initial version of the grid. Semi-structured interviews were conducted with nine researchers to collect their perspectives, assess the clarity and utility of the tool, and identify improvements. Their feedback was analyzed and integrated into a revised version of the grid, which was then presented to GMFU representatives for validation.

Results: Researchers endorsed the overall content and structure of the grid and confirmed its relevance for guiding project submissions. They suggested shifting from an approval/rejection mechanism to a collaborative evaluation process conducted with the researchers of each project. This approach emphasizes co-construction rather than gatekeeping and allows the RRSPUM to support teams in adapting protocols to GMFU operational constraints and workflows.

Discussion: The participatory nature of the process fostered a deeper mutual understanding between clinical teams and academic researchers. It also highlighted the importance of early dialogue to optimize project design, promote feasibility, and ensure alignment with GMFU priorities and capacities. GMFU representatives expressed a positive reception to the revised grid and recognized its potential for improving the relevance and applicability of projects submitted to their sites.

Conclusion: The development of this assessment grid illustrates the benefits of integrating collaborative practices into the evaluation phase of research. By structuring expectations and facilitating constructive exchanges, this approach strengthens partnerships and enhances the relevance, feasibility, and overall impact of research conducted in primary care settings.

ID 83- Inositol Supplementation and Insulin Resistance: A Mini Systematic Review of Clinical Evidence

Viviane TRAN [(1)], Marie-Thérèse LUSSIER [(1)], Claude RICHARD [(1)], Clara DALLAIRE [(2)], Marie-Hélène GOULET [(2)], Marie-Eve LAVOIE [(1)], Caroline ST-DENIS [(3)], Anne DUBÉ [(3)], Marie-Pier LEHOUX [(3)]

(1) Centre De Recherche Du Centre Hospitalier De L'université De Montréal, Montreal, Canada
(2) Université De Montréal, Montreal, Canada
(3) Ciusss-De-L'est-De-L'île-De-Montréal, Montreal, Canada

Context: In Quebec (Canada), the Primary Care Access Point (Guichet d'accès à la première ligne – GAP) enables patients without a family physician to access primary care for non-urgent concerns. However, GAP consultations pose several challenges: clinicians are unfamiliar to patients, many of whom present complex needs, and appointment times are short. These conditions can create barriers to clear communication and shared understanding. To improve communication quality, patients are invited to use Getting Ready (GR), an accessible, structured preparation tool previously validated in other healthcare contexts (https://gettingready.ca/). GR helps patients articulate their concerns, describe the impact of their problem, and formulate questions prior to the consultation.

Objectives: To examine how GR influences communication quality and interaction processes between orphan patients and GAP clinicians.

Methods: This prospective observational study is conducted in a regional GAP and five primary care clinics offering GAP appointments. Participants include healthcare professionals (n = 10) and adult patients, referred for GAP consultations and invited to complete GR online before their visit (target n = 200). Data sources include post-visit patient

questionnaires, clinician questionnaires, and focus groups with both patients and clinicians. Data collection is ongoing; final results will be available at the time of the conference.

Results: Based on prior evidence showing that GR improves patient–provider communication in various care settings, we anticipate greater clarity in patient concerns, better prioritization of issues during time-limited visits, and more efficient, patient-centred dialogue in GAP consultations.

Discussion: Evidence from other contexts suggests that preparation tools like GR can reshape the consultation dynamic by helping patients focus, organize their concerns, and feel more confident when meeting unfamiliar clinicians. In GAP settings, GR may reduce communication barriers linked to patient complexity and short appointment lengths. The study will also shed light on how preparation tools influence workflow, clinician experience, and patient engagement. Identifying facilitators and barriers specific to the GAP model will be essential for informing implementation at scale and adapting the tool to diverse primary care environments.

Conclusion: GR represents a promising, scalable tool to support patient preparation and strengthen the quality of primary care encounters across first-line access systems.

ID 822- Insect Presence in the Ears of Children: An Environmental Case Series from a Family Health Center

Roxane LIARD, Jasmine JAYYOSI, Victorien LAHSEN

Ipso Santé, Paris, France

Context: Fever phobia (FP), defined as parents' disproportionate fear of their child's fever, leads to inappropriate behaviours and persists despite medical progress and increasing access to health information.

Objectives: To provide an updated overview of current knowledge on FP and to identify effective educational strategies for managing it in primary care through a narrative literature review.

Methods: A narrative literature review was conducted using PubMed and Google Scholar. Search equations targeted studies addressing FP among parents and healthcare providers caring for children aged 0–18 years, as well as educational interventions related to fever management in primary care. Eligible articles were open-access, written in English or French, and published between 2014 and 2025. All included studies underwent a risk-of-bias assessment.

Results: The search identified 745 articles, of which 49 met eligibility criteria. Among these, 30 focused on parents, 7 on healthcare professionals, and 10 on both groups. Lack of knowledge as a key driver of FP was reported in 65% of studies, while misconceptions about fever appeared in 41%. Non-recommended prescribing and fever-management practices were noted in 51%. Low socioeconomic or educational level was identified as a risk factor in 18% of studies. Emotional factors contributing to FP were highlighted in 16%. Educational tools—such as brochures, videos, apps, or simulation—showed positive effects in 22% of studies, though their impact was strengthened when accompanied by a trusting relationship with the healthcare provider (reported in 16%). The central role of medical communication emerged clearly: 35% of studies emphasized the need for consistent messaging, and 29% highlighted gaps in healthcare providers' training on fever management.

Discussion: Risk-of-bias analysis revealed an overall moderate to high risk, mainly related to selection bias (limited sample diversity) and outcome-reporting bias. These limitations reduce the generalizability of findings and underscore the need for more rigorous studies with comprehensive data reporting.

Conclusion: FP is a complex, multicultural phenomenon, and changing deeply rooted beliefs and practices remains challenging. However, a multifaceted approach combining improved provider training, accessible educational tools, and targeted communication

may help reduce parental anxiety. Given its close contact with families, primary care appears to be the most suitable setting for addressing FP effectively.

ID 402- Integrated Project for the Eradication of Intimate Partner Violence: A Multisectoral and Community-Based Approach

Elson Romeu FARIAS [(1)], Carlos Alexandre HEINEN [(2)], Ana Amélia MACIEL [(2)]

(1) School Of Public Health – Ses/rs, Porto Alegre, Brésil
(2) Municipal Secretariat Of Health, Venâncio Aires, Brésil

Context: Tobacco is a driving force in the economy of xxx and, at the same time, contributes to the high overall mortality rate

Objectives: To characterize the factors that interfere with the adherence of smokers to smoking cessation groups. Thus, to construct a managerial educational product with guidelines on factors that enable increased adherence to smoking cessation groups, improving the training of health professionals on the subject

Methods: An integrative literature review was conducted using BDENF, PubMed, and BVS/LILACS databases, targeting studies published between 2015 and 2025. Inclusion criteria comprised full-text articles in Portuguese,found through the following descriptors: "Smoking" or "Primary Health Care" or "Health of Specific Groups" or "Tobacco Use Cessation"

Results: In total, 75,551 studies were identified in the initial search. Subsequently, main filters were applied using the following themes: smoking cessation, tobacco use cessation, tobacco use, smoking, and smoking prevention,Thus, 335 articles were selected. After reading titles, abstracts, and full articles, 7 articles were included for integrative review. This selection was carried out between June and August 2025.

Discussion: The insufficient preparedness of Primary Care teams constitutes the main factor associated with non-adherence among participants already enrolled in smoking-cessation groups. As this lack of preparedness persists, the number of unmotivated individuals enrolled in such groups increases—the second leading cause of non-adherence. Consequently, the primary factor reinforces and exacerbates the second. Thus, the development of a tool that outlines the organization of smoking-cessation groups in Primary Care, in accordance with the xxx guidelines, and that enhances program visibility, is warranted. Such a resource would support the formation of higher-quality smoking-cessation groups within Primary Health Care, improving adherence among enrolled participants and promoting the engagement of non-enrolled populations (including Afro-descendant individuals and men).

Conclusion: The results showed that the lack of training of primary health care teams and the lack of motivation of users are the main barriers to patient adherence to smoking cessation groups

Sheila Torquato HUMPHREYS [(1)], Miguel VIEIRA [(2)], Maria Teresa SILVA [(3)]

(1) Nova School Of Law Of The University Nova Of Lisbon, Lisbon, Portugal
(2) Center For Bioethics Research / Nova School Of Law Of The University Nova Of Lisbon, Lisbon, Portugal
(3) Faculty Of Medicine Of The Catholic University Of Portugal, Lisbon, Portugal

Context: With human missions to Mars becoming realistic, primary care physicians may soon be called upon to act as crew medical officers (CMOs). This role would extend GPs' responsibilities to include bioethical decision-making around potential exposure to Martian microbes, containment breaches, and planetary protection. This review explores how existing literature across primary care, ethics, and space medicine can inform this emerging challenge.

Objectives: To assess and synthesize academic and policy literature that supports the ethical, clinical, and operational role of GPs in scenarios involving planetary protection and interplanetary microbial exposure.

Methods: We conducted a structured review of academic databases (PubMed, JSTOR, Scopus) and grey literature from key agencies (WHO, ESA, NASA, UN-COPUOS, COSPAR). We prioritized literature on general practice, bioethics, space medicine, and planetary protection policies. Terrestrial equivalents (pandemic ethics, remote care, biosafety) were included for applicability. Inclusion criteria: relevance to clinical or ethical decision-making in isolation or novel biological hazard environments.

Results: Key findings show strong alignment between GPs' core competencies and the demands of planetary protection protocols. WHO and WMA ethics guidelines emphasize proportionality, psychological support, and least restrictive quarantine—mirroring COSPAR policies requiring containment for astronauts exposed to Martian material. GPs' pandemic experience reinforces their leadership in risk communication, mental health, and triage. Literature from space agencies anticipates CMO involvement in isolation decisions and contamination mitigation, positioning GPs as de facto bioethical stewards during spaceflight. Terrestrial parallels—Antarctic medicine, COVID-19 response, and biosafety levels—highlight transferable lessons.

Discussion: GPs already possess critical frameworks for managing uncertainty, isolation, and ethical risk. Applying these to spaceflight enhances mission resilience and underscores GPs' value beyond Earth. However, gaps remain in formal training around planetary bioethics and space operations.

Conclusion: This review affirms the relevance of general practice in planetary protection. GPs are well-positioned to integrate clinical care with ethical and environmental safeguards in future Mars missions. We recommend incorporating space-relevant bioethics into primary care training and encouraging interdisciplinary dialogue to prepare for this frontier of care.

ID 135- Integrating Digital AI Assistance (ChatGPT) into General Practice Workflow: A Practice-Based Reflection on Efficiency and Patient Safety

Çiğdem DELICE SEZGIN, Oğulcan ÇÖME, Vildan MEVSIM

Dokuz Eylül University Faculty Of Medicine, Department Of Family Medicine, Izmir, Türkiye

Context: Chronic abdominal pain, constipation and nonspecific neurological symptoms commonly present in primary care and are often attributed to functional disorders or stress. However toxic exposures such as lead poisoning may manifest with similar features and remain unrecognized. This case describes a 35-year-old man whose persistent symptoms were repeatedly considered nonspecific until a detailed occupational and hobby-related history revealed chronic lead exposure, highlighting the importance of broad differential diagnosis in primary care.

Methods: A 35-year-old man presented with three months of abdominal pain, constipation, fatigue and distal paresthesia. Earlier assessments had suggested functional gastrointestinal or stress-related conditions. During comprehensive history-taking, he reported a six-month hobby of melting and casting lead fishing weights at home in a poorly ventilated space without protective equipment. Symptoms began shortly after starting this activity. Physical examination showed pallor, abdominal tenderness, subtle wrist extensor weakness, and a faint Burton line. Laboratory tests revealed normocytic anemia, basophilic stippling, elevated zinc protoporphyrin and a blood lead level of 68 µg/dL, confirming chronic lead poisoning. He was referred for chelation therapy, stopped the exposure and received environmental safety counseling. Recognition occurred promptly once the exposure history was identified and his gastrointestinal and neurological symptoms improved within weeks.

Originality: Adult lead poisoning from home-based metal casting is rare and seldom reported in primary care. Most cases stem from occupational exposure or contaminated products. This case is distinct because the source was a personal hobby that initially mimicked benign conditions. Diagnosis in a Family Health Center underscores the critical role of primary care clinicians in detecting unusual environmental hazards.

Lessons learned and future implications: Clinicians should routinely inquire about environmental, occupational and hobby-related exposures when symptoms are chronic and multisystemic. Nonspecific complaints should prompt consideration of toxicologic causes. This case highlights the importance of early recognition, structured exposure screening and community education regarding safe metal handling.

Discussion: Lead poisoning is difficult to diagnose due to its nonspecific, multisystem nature. Delayed recognition reflects common patterns in environmental toxicities.

Conclusion: This case demonstrates how a seemingly harmless hobby can result in significant lead toxicity and reinforces the need for thorough exposure histories in primary care.

ID 913- Integrating Epidemiology, Patient Experiences and Workforce Upskilling to Develop Treat-to-Target Maintenance and Flare Pathways for Ulcerative Colitis in Rural Primary Care England

Ana Raquel FERREIRA

Usf Villa Longa, Uls Estuario Do Tejo, Lisboa, Portugal

Context: Adolescent obesity is a chronic, multifactorial condition recognised as a major global health challenge. Beyond metabolic complications, early adolescents frequently experience hidden psychosocial consequences such as body-shame, peer comparison, emotional eating and avoidance of social situations involving food. Primary care, with its continuity, accessibility and relational safety, is uniquely positioned to identify these invisible dimensions and provide early, person-centred support.

Methods: A 12-year-old boy presented with bilateral knee pain during football training. No musculoskeletal pathology was identified. Further exploration revealed significant psychosocial distress related to weight. A structured assessment captured patterns of emotional eating, cognitive restraint, external eating triggers and low body-appreciation, without depressive symptoms or red flags for eating disorders. Initial management included realistic dietary adjustments, maintaining physical activity without performance pressure and referral to psychology. Follow-up appointments monitored symptoms, engagement in sports, eating patterns and family dynamics. A multidisciplinary referral to Paediatrics and Nutrition was initiated.

Originality: This case demonstrates how a benign somatic complaint can act as a socially acceptable entry point for an adolescent to seek help for internalised distress. It highlights the importance of proactive psychosocial screening during routine primary care consultations.

Lessons learned and future implications: Early empathic enquiry into emotional drivers improved trust, disclosure and adherence. Recognising the psychosocial burden of weight-related issues is essential to guide appropriate interventions. Future practice should integrate structured, developmentally sensitive psychosocial assessments into adolescent consultations and strengthen multidisciplinary collaboration.

Discussion: The case illustrates that metabolic risk is only one dimension of adolescent obesity. Emotional factors - shame, guilt, comparison with peers and compensatory eating - may drive behaviours more strongly than biomedical variables. Addressing these early may prevent progression to disordered eating, social withdrawal and long-term psychological morbidity.

Conclusion: Meaningful management of adolescent obesity requires more than clinical metrics; it depends on addressing wellbeing,

identity, and emotional coping. Primary care is uniquely positioned to detect hidden suffering and coordinate holistic, patient-centred care.

(5) Urps Pharmaciens Ge, Nancy, France

Context: In 2024-2025, French Health Authorities organized two COVID-19 vaccination campaigns: a combined Flu/COVID-19 campaign in autumn, and an additional spring COVID-19 campaign targeting populations at higher risk. However, uptake for these campaigns remained modest, particularly during the spring campaign. Assessing the determinants of this low uptake is of particular interest.

Objectives: A consortium of non-governmental primary care organizations established during the first wave of COVID-19, conducted a survey among its network of primary health care workers (PHCWs). The goal was to assess their perceptions and acceptance of COVID-19 vaccination, both for their patients and themselves.

Methods: The study utilized a dedicated platform enabling PHCWs to participate in targeted surveys. An online survey (24 questions) was proposed to PHCWs between June and September 2025, with multiple email reminders. Participation was anonymous, and data were analyzed using Stata 11.2 software.

Results: Out of 1,021 vaccinating PHCWs who clicked on the survey link, 685 completed most of the key questions. Participants were predominantly general practitioners (GPs) (56%) and pharmacists (35%), mostly women (58%), and aged between 40 and 60 (52%). While 87% had received the influenza vaccine, only 44% were vaccinated against COVID-19 in 2024-2025. Regarding COVID-19 infections knowledge, most respondents felt they had the necessary medical information for their practice, except for current epidemiological data (only 68% felt informed). Access to organizational information (required for implementing vaccination) and scientific data (needed to assess the benefit/risk balance of available COVID-19 vaccines) was rated as moderate: 62% and 59% of PHCWs reported having access, respectively. Additionally, 20% indicated they lacked some of the information needed to answer patients' questions. Finally, although health authorities remained the primary source of information, their communication was deemed insufficient and unsatisfactory by 55% of respondents.

Discussion: This survey reveals a clear need for better scientific and organizational communication targeted at PHCWs, as well as stronger communication efforts related to COVID-19 vaccination campaigns. Comparable results had already been highlighted in previous surveys on vaccination.

Conclusion: Filling this communication gap seems essential, as numerous recent studies highlight the pivotal role of PHCWs in improving vaccination rates.

Context: In family medicine training Internationalism Is Good! Students should

experience different health care systems and cultures. In Scotland, with partners worldwide, we have designed and implemented an international elective programme for undergraduate and postgraduate students. We have done so without institutional backing or finance. Our programme depends upon the collaboration of a network of enthusiastic general practitioners across Scotland, from practices both urban and remote and rural. We ensure some academic input, and also include health policy makers, experts on health inequalities and we expose our students to Scotland's rich cultural life from opera to football. Electives must be free-spirited and adaptable. Minimally proscriptive. Maximally designed for the curious. The key word is camaraderie.

Objectives: We agree that cross-border learning is a good thing. We learn to communicate across borders. We build the structures and links. We all learn another language.We come together in a conference room. We interact. We look at models of international teaching, the similarities and the differences.

Teaching method and workshop: A short but image-rich introduction. Testimony from our students and our tutors. Small group work. A long and warm wash-up. Our tutors and students are multi-faceted and international. (We shall present in English, though noteworthy that two of our partic

Expected outcomes: We finesse the detail – Who will teach? What locations? We return home and individually recruit SIX COLLEAGUES in our country of origin. As in Six Craws Sitting on a Dyke, a James MacMillan premiere at the Edinburgh International Festival 2025. Participan

Conclusion: Electives in general practice for students are less available than they should be. Such electives are a splendid opportunity to demonstrate the rich diversity and fascination of generalist medicine. The model we present here is an effective way of promoting generalist medicine.

Context: To analyse the use of ambulatory blood pressure monitoring (ABPM) in Primary Care, describing patients' clinical characteristics by sex, the contribution of ABPM to the diagnosis of hypertension (HTN), and subsequent therapeutic changes.

Methods: A retrospective cross-sectional observational study was conducted using electronic health records from the Federica Montseny Health Centre (Madrid) between 2020–2022. Sociodemographic variables, comorbidities, clinical parameters, antihypertensive treatment and follow-up after ABPM were collected. A descriptive bivariate analysis was performed

Originality: A total of 166 patients were included, 57.6% were women, with a mean age of 62.7 years. Women showed a higher proportion of improved blood pressure control at one year (36% in men vs. 59% in women; p=0.003). In contrast, men exhibited higher rates of non-fatal cardiovascular disease (CVD) at 3 years (21% vs. 8%; p=0.017), diabetes (43% vs. 15%; p=0.002), previous ischemic heart disease (17% vs.1%; p<0.001), peripheral arterial disease (17% vs. 1%; p<0.001), and mortality due to target-organ damage (47.8% vs. 2.1%; p<0.001). Men also had a higher proportion of modified control at one year after ABPM (69.6% vs. 42.1%; p=0.014). Treatment changes were introduced in 59% of all patients and were more frequent among those with newly diagnosed HTN (39% vs. 15%; p<0.001).

Lessons learned and future implications: The high rate of treatment modification illustrates

the clinical impact of ABPM in refining risk stratification and guiding management.

Discussion: The study confirms the usefulness of ABPM in Primary Care for improving the diagnosis and management of hypertension. Although men and women showed similar baseline risk profiles, women achieved greater improvement in blood pressure control at one year, while men experienced higher rates of cardiovascular events, consistent with their higher baseline risk.

Conclusion: ABPM is an essential tool in Primary Care for confirming or ruling out HTN, optimising treatment, and identifying patients at increased cardiovascular risk.

Maria Teresa SILVA [(1)], Sheila Torquato HUMPHREYS [(2)] , Miguel VIEIRA [(2)]

(1) Faculty Of Medicine Of The Catholic University Of Portugal, Lisbon, Portugal
(2) Nova School Of Law Of The University Nova Of Lisbon, Lisbon, Portugal

Context: Long-duration spaceflight is rapidly shifting from governmental programmes to expanding commercial ventures. Missions beyond low Earth orbit—especially lunar and Martian initiatives—pose significant physiological risks, including muscle atrophy, bone loss, neuro-ocular changes, and radiation exposure. Emerging literature discusses "biohacking" approaches such as pharmacological optimisation, somatic gene therapy, and technological augmentation to enhance resilience. Although largely experimental, these interventions may soon become relevant for private space travellers. Primary care physicians, who already manage complex decisions with limited certainty, will increasingly encounter spaceflight-related health questions.

Objectives: This literature review examines scientific, medical, ethical, and legal publications to identify how enhancement technologies might influence primary care practice. It assesses challenges currently discussed within astronaut health that may soon be applicable to civilian populations.

Methods: A structured review of peer-reviewed biomedical, bioethical, space medicine, jurisprudence, and space-law sources was undertaken. Databases included PubMed, Scopus, HeinOnline, and Google Scholar. Search terms combined "long-duration spaceflight", "human enhancement", "bioethics", "gene therapy", "informed consent", "space law", and "primary care". Inclusion criteria: publications addressing health risks of deep-space missions, enhancement strategies, ethical considerations in human research, and legal governance under international space treaties. Exclusion criteria: engineering-only documents and non-scholarly speculative material. Narrative synthesis was used.

Results: Three themes emerged. (1) Medical uncertainty: Most enhancement proposals lack long-term safety data, though the physiological pressures of deep-space missions make them scientifically appealing. (2) Ethical tension: Literature highlights risks of subtle coercion, blurred boundaries between therapy and enhancement, and challenges to meaningful informed consent in high-stakes mission environments. (3) Legal gaps: The Outer Space Treaty and related instruments contain no explicit guidance on biomedical modification of crew, creating uncertainty for clinicians and spaceflight providers.

Discussion: Although primary care increasingly engages with technological and ethical innovations, limited work connects astronaut health to general practice. Findings indicate that general practitioners may soon counsel patients preparing for private missions or later manage individuals who have undergone enhancement procedures.

Conclusion: As space travel becomes accessible, primary care will face new ethical and legal considerations. Familiarity with astronaut-oriented enhancement debates will help clinicians anticipate emerging challenges. This emphasises the need for early professional awareness as human spaceflight moves closer to routine civilian experience.

C.s Barrio Peral, Cartagena, Espagne

Context: Ptosis is a relatively common reason for consultation in primary care and is usually linked to benign conditions such as Bell's palsy, local eyelid disorders, or muscular diseases. However, when it appears in isolation, it may represent a diagnostic challenge and serve as a sentinel sign of serious neurological disease. The ability of family physicians to identify atypical features during routine assessment is crucial to ensure timely referral. This case illustrates how careful observation of a seemingly minor symptom triggered suspicion of central involvement from the first clinical contact.

Methods: The case was managed through initial clinical assessment in primary care, followed by urgent referral to hospital services. Diagnostic reasoning focused on identifying discrepancies inconsistent with a typical peripheral facial palsy. In the hospital setting, a comprehensive neurological examination and neuroimaging studies, including CT and MRI, were performed. A retrospective analysis of the case was later conducted to evaluate strengths, limitations, and implications for practice in primary care.

Originality: Although ptosis is most commonly associated with benign or peripheral causes, its isolated presentation as the first manifestation of an intracranial lesion is uncommon. This case highlights the critical role of primary care in detecting clinical clues that may indicate central pathology, contributing to scarce literature on such atypical presentations

Lessons learned and future implications: The case underscores the importance of thorough neurological evaluation in any eyelid abnormality and the need to maintain a high index of suspicion, particularly in older patients or when findings deviate from classic Bell's palsy. It suggests the value of developing clearer referral pathways that prioritize urgent assessment when isolated ptosis lacks an identifiable cause.

Discussion: This case reinforces the essential function of primary care in recognizing early neurological signs and ensuring effective coordination with hospital services. Early identification of atypical ptosis may help prevent delays in diagnosing potentially serious intracranial conditions.

Conclusion: Isolated ptosis can be the first clinical indication of an intracranial lesion, and its early recognition in primary care is vital to improving patient outcomes. Keywords: Ptosis; Primary care; Space-occupying lesion; Early diagnosis; Facial palsy; Neurology.

ID 1871- Interactive ECG presentation of Brugada syndrome case report

Aayushi PANWAR

Hyderabad, Hyderabad, Inde

Context: As a first-generation doctor practicing in a community where chronic disease literacy is low and cultural norms heavily influence health choices, I often witness preventable complications arising from gaps in primary care engagement. This reflection examines the case of a 53-year-old woman—my relative—whose death from uncontrolled diabetes revealed systemic vulnerabilities and highlighted the need to re-emphasise equity, liberty, humanism, and fraternity in primary healthcare.

Methods: The patient, a grandmother of three and an avid traveller, had long-standing diabetes but remained non-adherent to treatment. She rarely underwent blood tests, frequently consumed sweets, and regularly practiced prolonged fasting during festivals.

Despite progressive symptoms such as fatigue and dyspnoea, she had no structured follow-up within primary care. She presented acutely with decompensated heart failure and required ICU admission for 15 days, ultimately succumbing to multi-organ deterioration. The case reflects how cultural autonomy, limited health understanding, and inadequate continuity of care can converge into preventable, life-threatening outcomes.

Originality: This reflection is unique because it merges personal grief with professional analysis. As a first-generation physician, witnessing a preventable death within my own family illuminated how cultural norms and low health literacy converge to create barriers—even for those with direct access to a doctor. It exposes the paradox that proximity to medical knowledge does not always guarantee adherence.

Lessons learned and future implications: The case reinforced that equity in primary care extends beyond access to include culturally informed education, compassionate communication, and regular, proactive follow-up. It highlighted the importance of respecting autonomy while guiding behaviour change empathetically. Fraternity—shared community responsibility—emerged as a critical pillar in chronic disease prevention.

Discussion: This case illustrates persistent gaps in primary healthcare: inadequate screening, weak continuity of care, and limited contextual counselling around cultural rituals such as fasting. Strengthening primary care requires integrated chronic disease programmes, community-based diabetes education, and sustained doctor–patient relationships rooted in trust, humanism, and shared decision-making.

Conclusion: This reflection advocates for fostering long-term doctor–patient relationships that blend scientific guidance with empathetic communication. By strengthening the pillars of liberty, equity, and fraternity, primary healthcare can prevent such tragedies. Ultimately, we must ensure that chronic disease management becomes a shared, supported journey rather than an isolated individual struggle.

ID 1388- Interdisciplinary Approach to Thymoma: The Role of the Family Physician in Early Diagnosis and Curative Treatment

Zoia PROKHORENKOVA, Viktoriia KOSTRYKINA

Obolon District Clinical Diagnostic Center, Kyiv, Ukraine, Kyiv, Ukraine

Context: Eosinophilic granulomatosis with polyangiitis (EGPA) is a rare ANCA-associated vasculitis characterized by asthma, eosinophilia, and multisystem involvement. Early phases often mimic isolated allergic or respiratory disorders, leading to delayed diagnosis in primary care. Recognizing “red flags” in patients with persistent eosinophilia and atypical asthma is essential to prevent organ damage.

Methods: A 51-year-old woman presented with a three-year history of progressively evolving symptoms. The first episode was generalized urticaria after outdoor work, requiring hospitalization. Eighteen months later, she developed persistent cough and was diagnosed with IgE-mediated asthma. Despite therapy, exacerbations persisted, starting with nasal congestion, postnasal drip, and “nasal” voice, followed by dyspnea and non-productive cough. During the last year, intermittent petechiae appeared and resolved spontaneously. Her history included chronic pansinusitis and seasonal allergic rhinitis. Family history was significant, as her sister had granulomatous vasculitis. Laboratory evaluation revealed persistent eosinophilia (up to 60%). The final diagnosis was eosinophilic granulomatosis with polyangiitis, chronic course, with pulmonary involvement, pansinusitis, and cutaneous manifestations.

Originality: This case demonstrates the classical phased evolution of EGPA: allergic manifestations → asthma → systemic vasculitic signs. The combination of recurrent urticaria, intermittent petechiae, chronic rhinosinusitis, eosinophilia, and family history highlights early

diagnostic clues often overlooked in primary care.

Lessons learned and future implications: Persistent eosinophilia in asthma should prompt evaluation for systemic vasculitis. Recurrent skin lesions, chronic rhinosinusitis, suboptimal asthma control, and positive family history are "red flags." Early recognition and specialist referral can prevent organ damage and improve outcomes.

Discussion: EGPA often presents initially with isolated allergic or respiratory symptoms, delaying diagnosis. Recognizing symptom clusters, including eosinophilia, skin manifestations, and rhinosinusitis, allows earlier detection. Awareness of the classical phased evolution aids primary care physicians in timely referral.

Conclusion: Heightened suspicion for EGPA in patients with asthma, persistent eosinophilia, and recurrent cutaneous or sinonasal manifestations enables early diagnosis, specialist referral, and improved prognosis.

Patricia Maria WIZIACK ZAGO, Júlia Peçanha PEÇANHA RODRIGUES, Lisie TOCCI JUSTO

São Leopoldo Mandic Medical School, Araras, Brésil

Context: Violence against women (VAW) remains a major public health and human rights concern in Brazil. The COVID-19 pandemic intensified social stressors, potentially modifying patterns of domestic violence. Understanding these trends is essential for strengthening primary care responses and informing international public health policy.

Objectives: To compare femicide rates and national hotline reports of VAW during the pandemic (2020–2022) and post-pandemic (2023–2025) periods, and to assess whether differences were statistically significant.

Methods: A retrospective analysis of government datasets was conducted using femicide counts from national security records and Ligue 180 hotline reports. Data were grouped into two periods: pandemic (2020–2022) and post-pandemic (2023–2025). Mean values were compared using independent samples T-tests, with statistical significance defined as $p<0.05$. Partial 2025 data were proportionally adjusted. Percentage changes were calculated to evaluate relative variation between periods.

Results: The mean number of femicides increased from 1,388/year during the pandemic to 1,452/year post-pandemic, representing a 4.6% rise, although this difference was not statistically significant ($p = 0.18$). Hotline reports showed a marked increase, rising from 89,233/year to 110,911/year, corresponding to a 24.3% increase, which was statistically significant ($p = 0.03$). Between 2020 and 2024, femicides increased modestly (1,355 → 1,459), while hotline reports grew substantially (82,991 → 132,084), suggesting more frequent reporting of non-lethal forms of violence.

Discussion: The data indicate that lethal violence against women remained relatively stable across the pandemic and post-pandemic periods, while reporting of non-lethal violence increased significantly after the pandemic. This divergence may reflect increased awareness, improved access to reporting mechanisms, or heightened incidence driven by socioeconomic pressures. Primary care settings—often the first point of contact for women experiencing violence—must adapt to this rising demand by strengthening screening, training, and integrated referral pathways. Moreover, Brazil's experience may inform international strategies, particularly in regions facing similar post-pandemic social vulnerabilities. Limitations include potential underreporting, changes in classification practices, and reliance on aggregated national data.

Conclusion: Post-pandemic Brazil experienced a significant rise in hotline reports of VAW but no statistically significant increase in femicide rates. These findings highlight the need for enhanced post-pandemic surveillance,

community-based prevention strategies, and primary care interventions to address the growing burden of gender-based violence.

ID 759- Interventions promoting physical activity among general practitioners: a systematic literature review

Elson Romeu FARIAS [1] , Lenita Franz BEZERRA [2], Débora Rutz DOS SANTOS [3]

(1) School Of Public Health – Ses/rs, Porto Alegre, Brésil
(2) Municipal Secretariat Of Health, Canoas, Brésil
(3) Catholic University Of Pelotas, Pelotas, Brésil

Context: Cardiovascular diseases constitute a major group of chronic non-communicable diseases (NCDs) of greatest relevance to public health in xx. Systemic Arterial Hypertension (SAH) is an NCD recognized as one of the leading independent and reversible risk factors for cardiovascular disease. In xx, primary care—owing to its comprehensive, patient-centered, and community-based model—ensures greater accessibility and reach for the prevention and early detection of conditions such as SAH.

Objectives: To characterize the profile of individuals diagnosed with systemic arterial hypertension who were registered with and monitored by a Family Health Strategy (FHS) team in a Primary Health Care Unit in the municipality of xx

Methods: This was a retrospective, cross-sectional epidemiological study with a quantitative approach, based on secondary data extracted from the Integrated Health Management and Services System (SIGSS) of xx. Electronic medical records of 292 individuals with SAH, followed between January 2022 and December 2024, were evaluated regarding sociodemographic variables, clinical characteristics, risk factors, target-organ damage, pharmacotherapy, and cardiovascular risk stratification.

Results: There was a predominance of female participants (64.4%) and of individuals aged 60–69 years, highlighting the association between SAH and aging. Most patients were classified as White (85.3%). Excess body weight was highly prevalent, with 35.3% presenting overweight and 24% class I obesity. Modifiable factors such as smoking, alcohol consumption, and physical inactivity showed a high proportion of missing data. Diabetes mellitus was identified in 28.1% of the sample.

Discussion: Regarding target-organ damage, 29.1% had a history of cardiovascular disease, notably stroke, myocardial infarction, and chronic kidney disease. Antihypertensive therapy was used by 96.7% of participants, with frequent combination regimens involving ARBs/ACE inhibitors, thiazide diuretics, and beta-blockers. However, formal cardiovascular risk stratification was absent in 79.8% of the records. Among those with documented risk classification, most were categorized as high risk, although a portion were not receiving high-intensity statins as currently recommended.

Conclusion: Although clinical follow-up is provided, significant gaps persist in risk stratification and in the recording of essential information, directly affecting primary care's capacity to plan and guide interventions. The findings underscore the need for improved documentation practices, continuous professional development, and the adoption of standardized protocols.

ID 322- Interventions to reduce Energy Poverty and their impact on Mental Health: a systematic review

Maria Teresa SILVA [1], Sheila Torquato HUMPHREYS [2] , Miguel VIEIRA [2]

(1) Faculty Of Medicine Of The Catholic University Of Portugal, Lisbon, Portugal
(2) Nova School Of Law Of The University Nova Of Lisbon, Lisbon, Portugal

Context: As commercial spaceflight expands globally, primary care physicians may increasingly be asked to assess and clear patients for space tourism or suborbital travel. The medicolegal and ethical landscape for such pre-flight evaluations remains underdeveloped, with implications for liability, informed consent, and cross-border

jurisdiction. No consolidated review exists to guide primary care practice in this context.

Objectives: To examine existing international legal treaties, national regulations, space agency guidance, and published policy literature regarding medical screening, jurisdiction, and informed consent for commercial spaceflight participants, with particular attention to the role of primary care.

Methods: A structured literature review was conducted using databases (PubMed, HeinOnline, Google Scholar) and grey literature from NASA, FAA, ESA, UN COPUOS, UK CAA, and relevant national legislation between 2004–2025. Search terms included "spaceflight participant," "informed consent," "aerospace medicine," "liability," "primary care," and "jurisdiction." Inclusion criteria: legal/policy/scientific publications relating to pre-flight medical screening, patient safety, and clinician responsibility. Sources were qualitatively synthesized to identify regulatory commonalities and gaps.

Results: Global legal frameworks derive from the Outer Space Treaty and Liability Convention, assigning jurisdiction to the launching state. The U.S. and U.K. require informed consent waivers disclosing the risks of unregulated human spaceflight. FAA guidelines recommend—but do not enforce—aerospace medical screening tailored to flight profiles. ESA and ISS partners define standards for "spaceflight participants" but these apply only to state-supported missions. No national regulations explicitly assign legal responsibility to primary care providers, yet doctors may face liability if screening is inadequate. Significant regulatory gaps persist in China and Japan. Across jurisdictions, consent practices, certification roles, and liability standards vary or remain undefined.

Discussion: The medicolegal framework for commercial spaceflight remains fragmented, and current laws focus more on operators than on clinicians. However, primary care physicians may be drawn into this evolving ecosystem through routine patient care, requiring clarity on their legal exposure, ethical duties, and referral responsibilities.

Conclusion: Policymakers should develop international guidelines clarifying the clinical and legal responsibilities of non-specialist physicians in pre-spaceflight assessments. For now, GPs should follow aerospace medicine best practices, ensure robust informed consent, and document decisions thoroughly when approached for fitness evaluations.

ID 912- Introduction of short, mobile-friendly e-learnings for general practitioners: first experiences among users

Elson Romeu FARIAS [(1)], Gabriela MULLER LEHMEN [(2)], Rafael Angelo RIBEIRO CHIABAI [(2)]

(1) School Of Public Health – Ses/rs, Porto Alegre, Brésil
(2) Municipal Secretariat Of Health, Farroupilha, Brésil

Context: Systemic arterial hypertension represents the most prevalent morbidity among adults, affecting an estimated 30% of the xxxx population. Its predominantly asymptomatic course contributes to delayed diagnosis and constitutes a major challenge for health systems, particularly regarding adherence to prescribed therapeutic regimens. Current estimates indicate that fewer than half of hypertensive individuals achieve satisfactory medication adherence, resulting in suboptimal blood pressure control and heightened risk of adverse cardiovascular outcomes

Objectives: To identify and synthesize evidence on interventions that enhance adherence to pharmacological treatment for systemic arterial hypertension.

Methods: An integrative literature review was conducted using SciELO, PubMed, and BVS/LILACS databases, targeting studies published between 2015 and 2025. Inclusion criteria comprised full-text articles in Portuguese, Spanish, or English that addressed strategies to promote medication adherence within the context of Primary Health Care. Eight studies met the eligibility criteria and were subjected to qualitative synthesis.

Results: The selected studies demonstrated consistent evidence that multiprofessional

follow-up, electronic reminder technologies, structured health education, and the strengthening of patient–provider relationships were associated with improved adherence. Interventions integrating digital tools and ongoing counseling appeared particularly effective in sustaining long-term treatment engagement. Based on the synthesized evidence, a protocol adapted to local health system conditions was developed

Discussion: The reviewed studies exhibited substantial methodological heterogeneity, including variability in research designs, sample sizes, and adherence assessment instruments. Most samples were small and limited to local settings, restricting external validity. A scarcity of controlled clinical trials and multicenter investigations was noted, alongside a predominance of descriptive designs and isolated interventions, which hampers long-term impact evaluation. The studies highlight notable strengths: diverse, context-sensitive strategies in primary care, creative team adaptability despite structural constraints, and the transformative impact of group education and case-management practices driven by strong patient–provider relationships and continuous communication.

Conclusion: The findings underscore the practical applicability of evidence-based strategies to enhance treatment adherence in Primary Health Care settings. These approaches may inform the planning and implementation of continuous and resolutive care actions for individuals with hypertension, while reinforcing permanent health education and longitudinal monitoring within the xxxx Unified Health System.

ID 1660- Investigation of the attitudes of nursing staff in Peloponnese hospitals towards telemedicine and health informatics applications

Andrea POPPELIER, Frédérique CHAIGNAUD, Pauline VILLIERS-MORIAMÉ, Samantha CONSTANTIN, Aline PARIS, Natacha COUTARD, Guillaume RENARD

Mspu Coeur De Saintonge, Saint Porchaire, France

Context: Dementia remains a non-reversible syndrome, with a prevalence of 6–8% among individuals over 65 years in France, increasing exponentially with age. Memory loss is therefore a major concern among patients over 60. Primary care offers an ideal setting for early detection. The Coeur de Saintonge Health Care Center (CSHCC), a rural multidisciplinary facility with 42 professionals (general practitioners, nurses, pharmacists, midwives, speech therapists, etc.), offers memory-loss screening to all patients over 60, and to younger adults reporting memory concerns. Between September 2024 and September 2025, 104 patients were screened; 68% had normal or sub-normal results (MMSE > 24). Despite reassuring results, many expressed anxiety about developing dementia and requested tools to maintain cognitive functioning.

Methods: Using a multidisciplinary approach, the CSHCC created a therapeutic patient education (TPE) program for patients with normal or mildly sub-normal screening results. On a voluntary basis participants join small groups (max. 8 patients) and complete a 3-month series of themed workshops: * Physiological aging and development of cognitive skills (gerontological psychologist) * Cognitive rehabilitation (speech therapist) * Hearing-loss screening (hearing-aid specialist) * Technical aids (occupational therapist) * Physical activity (activity instructor) * Nutrition (dietician) * Social activity and community engagement (occupational therapist + local association) Two cycles are offered annually. At year's end, both groups participate in a joint session to discuss how they integrated the recommendations into daily life.

Originality: While secondary care programs exist for moderate cognitive impairment, few comparable patient-education initiatives are available in French primary care. This program also strengthened patient engagement with the health center.

Lessons learned and future implications: This program encouraged general practitioners to screen earlier—before overt symptoms appear. The health care center additionally provides

support to participants interested in establishing a community organization with social and cognitively stimulating activities, thereby extending the program's impact and reinforcing local preventive strategies.

Discussion: Short-term evaluations highlighted improvements in social engagement, while long-term follow-up showed that participants proactively addressed broader health issues after completing the program.

Conclusion: The results of long term follow up suggests that a multidisciplinary primary-care TPE program can empower older adults to adopt preventive behaviors and reduce anxiety regarding cognitive decline.

Context: Lower limb amputation (LLA) is frequently performed for advanced vascular disease and diabetes and is associated with substantial morbidity and mortality. Contemporary nationwide data from Sweden on survival following first-time LLA have been limited.

Objectives: To investigate national and regional trends in survival time, mortality rates, and associations with amputation level, demographic factors, and comorbidities among all adults undergoing a first LLA in Sweden between 2008 and 2017.

Methods: This national observational cohort study included all individuals ≥18 years experiencing a first LLA (n = 16,757), identified through the Swedish National Inpatient Register and linked to the Cause of Death Register and socioeconomic data. Ten matched controls per case (n = 165,555) were selected by age, sex, region, and calendar year. Survival was assessed using Cox proportional hazards models, adjusted for demographics, socioeconomic status, comorbidities, and region. Outcomes included 30-day, 1-year, 3-year, and 5-year survival, median survival, and cause-specific mortality.

Results: Mortality was significantly higher after LLA compared with controls (adjusted HR (aHR) 3.32–3.69 across amputation levels). Median survival was 1.8 years among amputees versus 8.3 years in controls, and 5-year survival was 24.3% versus 66.2%. High proximal amputations had the poorest outcomes (median 1.0 year; 5-year survival 17.3%). Comorbidities markedly influenced mortality; chronic kidney disease (aHR 1.70), heart failure (1.44), dementia (1.42), and cancer (1.64) were strongest predictors. Diabetes was highly prevalent and associated with increased risk (aHR 1.21). Younger individuals had the highest relative mortality compared with matched controls. Vascular disease and diabetes dominated causes of death among amputees, contrasting with cancer and dementia in controls. Regional differences were modest but significant in several counties.

Discussion: LLA remains a strong marker of advanced systemic disease, and survival varies by amputation level, age, comorbidity burden, and socioeconomic factors. Despite advances in vascular and metabolic care, mortality remains high.

Conclusion: In Sweden, first-time LLA is associated with markedly reduced survival, particularly for high proximal amputations and people with severe comorbidities. These findings highlight the need for intensified preventive vascular care, multidisciplinary perioperative management, and targeted rehabilitation strategies.

ID 1851- Investigation of the Relationship Between Smartphone Use and Intuitive Eating Behaviour in Medical Students

Maarten CUYPERS, Monique KOKS-LEENSEN, Jip JANSEN, Marloes HEUTMEKERS, Pim VAN OIRSCHOT

Radboudumc, Nijmegen, Pays-Bas

Context: People with intellectual disability (ID), defined by limitations in cognitive and adaptive functioning, constitute a substantial subpopulation (1–3%). Their medical problems often differ from the general population, may present atypically, and frequently have a different onset or course. These factors contribute to major health disparities and a higher risk of premature mortality, up to 15 years earlier than people without ID. In many countries, general practitioners (GPs) are responsible for primary care for this group, while they often struggle providing adequate care to this complex patient group. This workshop aims to increase awareness and offer practical guidance to improve equity and quality of care for people with ID.

Objectives: In this session, participants will: - understand key challenges in accurately recognising and documenting ID; - gain insight into how people with ID experience GP care and how their disability is taken into account; - recognise important differences in medical problems and symptom presentation between patients with and without ID; - be able to apply practical strategies to better tailor their care.

Teaching method and workshop: The session will be structured according to four main themes: - Recognising and reporting ID in medical records - Experiences of patients with ID in GP care - Common health problems and atypical symptom presentation - Opportunities to tailor and adapt

Expected outcomes: Participants will: - Recognise challenges in identifying and documenting ID; - Understand key differences in health needs and patient experiences; - Learn and co-create practical strategies to better address specific health needs.

Conclusion: People with ID are a distinct and often underserved group in primary care. This workshop equips GPs with knowledge and practical approaches to reduce disparities and provide more equitable, tailored care to their patients with ID.

Context: For many family doctors, skincare can feel like a complex and sometimes intimidating topic, especially when faced with an ever-growing list of active ingredients, formulations, and evolving trends. Derma Trivia: Skincare Edition was created to bridge this gap by offering an approachable, enjoyable, and practical way to explore dermatology basics through play. This workshop welcomes participants with all levels of dermatology knowledge, including those who feel they are “starting from zero,” and invites them to learn together in a supportive environment.

Objectives: This workshop aims to: Introduce key skincare actives and their clinical uses in an accessible way. Improve understanding of common product formulations and when they are indicated. Present emerging skincare trends relevant to primary care practice. Strengthen clinical reasoning through short, practical case-based questions. Provide practical tips and tricks that can be immediately applied during consultations. Encourage engagement and

teamwork through competitive, game-based learning.

Teaching method and workshop: The workshop centres on the Derma Trivia board game, which contains six themed categories: • Actives • Formulations • Trends – • Clinical Cases • Tips & Tricks • Miscellanea Each category includes varied card types such as mul

Expected outcomes: Participants are expected to leave with increased confidence in recommending skincare products, understanding actives and formulations, and approaching skincare conversations with clarity and ease.

Conclusion: Derma Trivia: Skincare Edition transforms essential skincare principles into a dynamic, collaborative, and competitive learning experience. By blending concise theory with a playful team-based board game, the workshop empowers family doctors to approach dermatological skincare with confidence, curiosity, and a renewed sense of enjoyment.

ID 2238- Is an adequate medical history still an essential tool in family medicine?

Maria Inês LAVOURA RIBEIRO, Jéssica Carina AFONSO PERES, Pedro Alexandre SANTOS CARVALHO FIGUEIREDO, Isabel LOPES ALONSO, Nuno Daniel FERREIRA VEIGA

Unidade De Saúde Familiar Dólmen, Unidade Local De Saúde Do Baixo Mondego, Figueira Da Foz, Portugal

Context: Acrometastases are defined as metastatic lesions sited distally to the elbow or knee.

Methods: A 45-year-old man sought consultation at this health center in May/2025. Background: Alcohol-induced cardiomyopathy; Atrial fibrillation; COPD; Former drinker and smoker (85,5 pack-years); Two episodes of pneumonia in the previous year. While awaiting a public cardiology consultation, he had irregular follow-ups with a private cardiologist and a pneumologist. He presented with swelling of the left thumb that had started two months prior. He denied pain. An X-ray requested by a private orthopedist showed a lytic lesion at the base of the distal phalanx – the radiologist suggested an ultrasound. Meanwhile, during his first cardiology consultation in the public system, a coronary CT angiography (CCTA) was requested. Three weeks later, he came back with the result of the ultrasound: Bone tumor with defined margins involving the distal end of the proximal phalanx and most of the distal phalanx. A CT scan and an orthopedic oncology consultation were requested. One month later, he returned to renew his sick leave. At this appointment, he presented two new facial skin nodules that resembled keratoacanthomas, prompting a dermatology referral. Later that day, he went to the ER due to hemoptysis. The CCTA he had done showed extracardiac findings; consequently, a chest CT scan was performed – it revealed a hypodense left hilar lesion. He was hospitalized, and a bronchofibroscopy with biopsy confirmed the malignant etiology of the lesion (epidermoid carcinoma). The face and finger lesions were biopsied and turned out to be metastases. He's currently undergoing immunotherapy and chemotherapy.

Originality: Acrometastases are rare.

Lessons learned and future implications: This case made us aware of an unusual presentation of lung cancer.

Discussion: This patient had a major risk factor for lung cancer – high tobacco load. Although rare, acrometastases are frequently linked to this type of cancer and are associated with a grim prognosis. They can mimic various conditions, leading to misdiagnosis and treatment delays, hence the need for a high index of suspicion.

Conclusion: Family doctors should be aware that distal extremity lesions can represent metastatic disease, especially in high-risk patients.

ID 1433- Is Specialization compromising the Core Competencies of a family doctor?

Berk UMUT, Yasemin ÖZKAYA, Bakiye Nurdan TEKGÜL

Izmir City Hospital, Izmir, Türkiye

Context: Artificial intelligence (AI) is rapidly gaining importance in healthcare by contributing to diagnosis, decision support, risk prediction, image analysis, and training processes. The growing number of academic studies on AI-based applications in medicine and health sciences indicates that the integration of this technology into clinical practice is strengthening.

Objectives: Examining AI-focused theses in Türkiye both quantitatively and in terms of content is valuable for understanding adoption trends in the health field. Primary healthcare services—characterized by access to broad patient populations, opportunities for early diagnosis, and continuity of care—represent a particularly suitable area for AI use. Evaluating this potential is an important need for the national health system.

Methods: This study was conducted in November 2025 through the "ÖSYM TEZ" platform, where theses in Türkiye are uploaded. Theses in the "Medicine" category that included the term "artificial intelligence" in their titles were screened. They were evaluated through descriptive analysis according to thesis type, year, specialty field, and the purpose of AI use. In addition, theses related to primary healthcare services and the family medicine specialty were thematically grouped under a separate category.

Results: A total of 179 AI-themed theses produced between 2008 and 2025 show that thesis output has increased rapidly, especially in recent years. While only five theses were produced between 2008 and 2020, 97% were completed after 2021, with the highest concentration in 2023–2025 (84%). More than half of the theses were medical specialty theses (53.1%), followed by dentistry (20.1%), doctoral theses (14%), and master's theses (12.8%). AI applications were most frequently used for diagnostic and measurement purposes (25.7%), followed by risk prediction (10.1%), education–rehabilitation (13.4%), and attitude–anxiety studies (6.1%). Eight theses in family medicine were grouped into four themes: diagnostic applications, education–attitude studies, evaluation of large language models, and polypharmacy management.

Discussion: AI theses in Türkiye have rapidly increased, focusing on clinical fields; family medicine involvement is emerging, but broader applications and prospective studies are still needed.

Conclusion: AI-themed theses in Türkiye have increased markedly after 2021, are concentrated in clinical areas, and hold significant potential for supporting early diagnosis, continuous care, and educational processes

ID 1117- Is what I see really what I see?

Sameer JOSHI [(1)] , Prathamesh KOTAGI [(2)]

(1) Associate Professor, Ponda, Goa, Inde
(2) Assistant Professor, Kolhapur, Maharashtra, Inde

Context: Functional gastrointestinal disorders (FGIDs), including irritable bowel syndrome (IBS) and functional dyspepsia, are common in primary care and significantly affect daily functioning. Dietary patterns are central to symptom fluctuation. Ayurvedic dietary regulation (ahara chikitsa) emphasizes individualized guidance on food quality, timing, combinations, and digestive support, offering a potentially low-cost, non-pharmacological adjunct to routine care.

Objectives: To evaluate the impact of ayurvedic dietary counselling on symptom severity and quality of life among young adults with FGIDs.

Methods: A prospective interventional study was conducted among adults aged 18–35 years diagnosed with FGIDs using Rome IV criteria. Participants received individualized dietary counselling based on ayurvedic principles, including structured meal timing, avoidance of incompatible food combinations, personalized diet charts, and digestive-supportive practices. Outcomes were assessed at baseline and at 4-week follow-up using the Symptom Severity Score (SSS), Gastrointestinal Quality of Life Index (GIQLI), and a patient-reported overall improvement scale. Pre–post changes were analyzed using paired t-tests.

Results: Among 40 participants, 37 completed follow-up. Mean SSS reduced from 315 to 184 ($p < 0.001$), and mean GIQLI improved from 82.6 to 104.3 ($p < 0.001$). A total of 81% of participants reported reduced bloating and 76% noted improved bowel regularity. No adverse effects were reported. Participants described high acceptability and satisfaction with a personalized, food-based approach.

Discussion: Ayurvedic dietary counselling was associated with clinically meaningful improvements in FGID symptoms and quality of life within a short timeframe. The individualized, non-pharmacological nature of the intervention aligns with patient-centered and preventive primary care principles.

Conclusion: Ahara chikitsa appears to be a feasible, acceptable, and effective dietary adjunct for managing FGIDs in young adults. Further controlled studies may support broader incorporation of tailored dietary guidance into primary care practice.

Arnila MELINA [(1)] , Mohd. Fikra Tri WIJAYA [(2)]

(1) University Of Muhammadiyah North Sumatra, Medan, Indonésie
(2) University Of Riau, Pekanbaru, Indonésie

Context: Wound care is a common task in family medicine, covering chronic ulcers, injuries, burns, and post-surgical wounds. In many primary-care settings, the high cost and limited supply of advanced dressings slow healing and widen care gaps. Honey, with its antimicrobial and healing properties, offers a practical alternative that fits these real-world constraints. However, primary-care experience using honey dressings is still rarely reported.

Methods: This reflection integrates routine wound management in primary care during 2024–2025 with an evidence-informed comparison of peer-reviewed studies published from 2018–2025. Across approximately 60 cases, honey was applied after saline cleansing and covered with non-adherent gauze, with dressing changes every 24–48 hours. Outcomes were monitored through serial wound assessments. In parallel, findings were compared with randomized trials and meta-analyses evaluating wound-area reduction, infection clearance, healing time, and pain.

Originality: While most studies on honey dressings originate from tertiary wound-care centers, this reflection highlights an underrepresented perspective: the integration of honey dressings within frontline family medicine. The experience demonstrates that honey is clinically effective, culturally acceptable, feasible for home-based care, and 30–50% more cost-saving than commercial dressings—advantages rarely emphasized in the literature. This model is highly scalable for low-resource primary care environments.

Lessons learned and future implications: Clinical observations showed 25–40% wound-area reduction by day 14, early granulation by days 4–7, fewer signs of infection, and a 1–2 point drop in pain scores. Patients adhered well to home dressing changes, costs were 30–50% lower than advanced dressings, and referrals to secondary care decreased.

Discussion: Honey's biological actions—osmotic debridement, low-level hydrogen peroxide activity, acidic pH, and anti-inflammatory effects—combined with affordability and accessibility, align closely with core principles of family medicine: continuity of care, equity, practicality, gatekeeping, and patient empowerment. This low-cost, evidence-informed intervention enhances the capacity of family physicians to provide effective wound care despite resource limitations.

Conclusion: Honey-based dressings represent a safe, effective, and feasible wound-care option for primary care. Their integration can accelerate healing, reduce costs, strengthen patient participation, and support more equitable wound management in underserved communities. This experience supports

adopting honey-based protocols as a practical component of routine family medicine practice.

ID 1193- Jurisdiction, Consent, and Clinical Responsibility in Pre-Flight Medical Screening for Space Travelers: A Review of Legal and Policy Literature Relevant to Primary Care

Christine ROSE

Überörtliche Berufsausübungsgemeinschaft Dr. Rose/ Balshüsemann, Goslar, Allemagne

Context: The increasing availability of synthetic opioids such as fentanyl poses new challenges for primary care–based opioid substitution treatment (OST). Traditional supervised dosing models can be resource-intensive and may create barriers for younger patients with emerging opioid use disorder (OUD). Long-acting buprenorphine depot formulations offer a promising alternative for a safe provision and low barrier access to OST. Buprenorphine—particularly when delivered via long-acting depot formulations—may reduce fentanyl-induced respiratory depression due to its high μ-opioid receptor affinity, partial agonism, and stable plasma levels. Evidence from studies suggests that adequate buprenorphine receptor occupancy can attenuate respiratory depression caused by fentanyl. However, real-world data from primary care settings remain limited.

Methods: A practice-based reflection was conducted using a combination of case-based observations, team discussions, and informal patient feedback gathered over a six-month implementation period. Key domains included clinical safety, workflow integration, patient engagement, and perceived impact on treatment adherence.

Originality: To reflect on the introduction of depot buprenorphine in a general practice setting, identify barriers and facilitators, and derive practice-relevant lessons for improving access and patient safety

Lessons learned and future implications: The introduction of depot buprenorphine led to improved medication adherence among patients at risk of fentanyl exposure and reduced concerns about diversion and misuse. The reflective process highlighted the importance of lowering access barriers and adopting a harm-reduction framework within primary care.

Discussion: The growing availability of synthetic opioids increases the risk of fatal overdoses. Depot buprenorphine offers a promising strategy to reduce this risk when implemented in low-threshold primary care settings. However, structural barriers and limited real-world data currently impede broad implementation and equitable coverage.

Conclusion: Practice-based reflection demonstrated that implementing long-acting buprenorphine in general practice is feasible, safe, and beneficial for patients with complex opioid use patterns. Adopting a non-paternalistic, harm-reduction–oriented approach can significantly improve the quality and accessibility of OST. These findings may guide other primary care settings facing increasing fentanyl-related risks.

ID 841- Key Considerations in the Design of a Sentinel Network for Drug Use: Qualitative Findings

Aayushi PANWAR, Syed Abdul Haq KAMAL

Hyderabad, Hyderabad, Inde

Context: Severe anemia in young women is a significant public health concern but is often approached solely through a biomedical lens. This practice-based reflection examines challenges of equity, patient autonomy, and humanism encountered while managing a young woman whose severe anemia was critically shaped by financial stress, family dynamics, and mistrust of the healthcare system.

Methods: A 22-year-old psychology student from a low socioeconomic background presented to with hypopigmented macules on back. She reported severe fatigue, weight loss, hair loss, pruritis and menorrhagia.

Examination revealed marked pallor. Her mother, the primary communicator, was distressed but resistant to further investigations, citing prior traumatic hospital experiences, financial hardship, and religious beliefs. Cost-prohibited barries led to only a CBC, revealing a hemoglobin level of 5.6 g/dL. Despite medical indications for urgent hospitalization and transfusion, the family firmly declined.

Originality: Management of severe anemia is typically protocol-driven; however, this case highlights the clinician's deliberate shift toward a harm-reduction approach. Rather than functioning solely as a specialist diagnostician, the physician navigated the tension between medical necessity and the patient's stated liberty—her refusal of hospitalization and transfusion. This reflection focuses on negotiating care within the patient's constraints, emphasizing humanism, empathy, and practical problem-solving instead of strict adherence to biomedical expectations.

Lessons learned and future implications: This case illustrates the ethical and systemic complexities that arise when biomedical priorities conflict with lived realities. The patient's refusal was a symptom of fear, inequity, mistrust and not non-compliance. By prioritizing a non-judgmental, humanistic approach, the clinician built sufficient trust for the family to disclose their true barriers. Within these constraints, a negotiated outpatient plan using oral iron, vitamin c, dietary changes became the only feasible option. The case underscores the essential role of longitudinal, trusted primary care in identifying and mitigating biopsychosocial barriers long before they escalate into emergencies.

Discussion: The case demonstrates that respecting autonomy while minimizing harm can be the most realistic path in inequitable contexts. Humanistic engagement enabled meaningful disclosure and feasible management.

Conclusion: This reflection exposes how equity gaps can turn a treatable condition into a crisis. For general practitioners, success lies not merely in clinical correction but in empowering patients within their socioeconomic realities.

ID 1949- Knowledge and Performance of Basic Life Support among Primary Health Care Professionals: An Integrative Review

Russ LI

National Centre For Infectious Diseases, Singapore, Singapour

Context: Current genetic risk scores for COVID-19 are derived mainly from European populations, creating a "health equity gap" for Asian patients in primary care. Furthermore, the biological basis of "Long COVID"—particularly the "brain fog" and fatigue frequently managed by General Practitioners (GPs)—remains poorly defined, limiting targeted management strategies.

Objectives: To identify population-specific genetic risk factors for COVID-19 severity and post-acute sequelae in a multi-ethnic Asian cohort (Chinese, Malay, Indian) to improve risk stratification in primary care.

Methods: We analyzed Whole Genome Sequencing (WGS) data from 45,797 individuals in a national cohort, linked to comprehensive national administrative health records. We performed ancestry-stratified GWAS and meta-analysis for acute phenotypes (Susceptibility, Severity) and Long COVID (Neurological, Cardiovascular). Cross-phenotype gene-burden tests (MAGMA) were conducted with Influenza and Invasive Bacterial infections to identify broad-spectrum host defense mechanisms relevant to community-acquired infections.

Results: We identified 10 genome-wide significant loci. For acute severity, we identified a novel risk locus in ADAMTS5 (P = 4.1 x 10-10), a metalloproteinase governing lung tissue remodeling. Cross-phenotype analysis revealed ANKS1B as a putative pleiotropic risk factor associated with susceptibility to Influenza, Invasive Bacterial infections, and COVID-19 (P = 4.1 x 10-9). Crucially, for Long COVID, we identified GRID2 (P = 9.7 x 10-10)—a cerebellar

glutamate receptor—as a top risk factor for post-acute neurological sequelae.

Discussion: The identification of ANKS1B suggests a subset of patients possesses a "pan-susceptible" mucosal barrier defect, making them "frequent flyers" for viral and bacterial respiratory infections in the community. Furthermore, the association of GRID2 with Neurological Long COVID supports a "Synaptic Failure" hypothesis for post-viral brain fog, moving the field beyond vague inflammation theories toward specific neural targets relevant to cognitive rehabilitation.

Conclusion: This study underscores the critical importance of non-European cohorts in refining genetic risk stratification. The findings support a precision medicine approach where GPs could prioritize individuals with "Pleiotropic" risk variants for broader vaccination strategies (e.g., Influenza and Pneumococcal) alongside COVID-19 prevention.

(3) Department Of Respiratory And Critical Care Medicine, Thoraxklinik At Heidelberg University Hospital, Heidelberg, Allemagne

Context: Oscillometry is becoming increasingly widespread because it allows lung function tests to be performed independently of patient cooperation. This procedure could enormously improve diagnostic decision making in primary care. However, the diagnostic accuracy with which asthma, COPD and, more generally, airway obstruction can be predicted remains unclear up to now.

Objectives: The aim was to determine the diagnostic accuracy of oscillometry for the detection of airway obstruction, and for the differential diagnosis of asthma and COPD.

Methods: Cross sectional diagnostic study. We consecutively recruited patients who came to a large pulmonologist's practice in ambulatory care in Munich for a routine examination. Index test: First, oscillometry was performed (key biomarkers: R5, R5-20, AX). Reference standard: After that, routine investigation with whole body plethysmography was performed. An obstructive airway disease was diagnosed when Forced Expiratory Volume in the first second / Vital Capacity (FEV1/ VC) was < 0.70. Two by two tables will be calculated to determine sensitivity, specificity, positive and negative predictive values for the detection of airway obstruction. Subgroup analyses are performed to determine the diagnostic accuracy for asthma and COPD.

Results: The recruitment process has been successfully completed. From early August to late October 2025, a total of 500 patients were recruited.

Discussion: The data is currently being entered and analysed. The final results will be presented at the conference.

Conclusion: The results of this large-scale diagnostic study in ambulatory care can help to better assess the diagnostic usefulness of oscillometry for primary care.

Context: Laceration repair is a frequent procedure in primary care and emergency settings, yet significant variability exists in technique selection, infection-prevention practices, and wound management skills.

Evidence shows that outcomes depend more on preparation, irrigation, and tension control than on the specific closure material used. However, many clinicians receive limited structured training after medical school, leading to inconsistency in clinical practice and reduced confidence. This workshop addresses this gap through an evidence-based, hands-on session integrating current best practices, updated international recommendations, and practical procedural skills.

Objectives: Participants will: Identify principles of wound assessment, preparation, irrigation, and anaesthesia based on current scientific evidence. Select appropriate closure techniques for different wound types and anatomical locations. Perform key suturing techniques, including simple interrupted, running, mattress, and deep dermal sutures, with correct tension management and wound edge eversion. Compare sutures, staples, and tissue adhesives and apply evidence-based criteria for choosing each method. Recognize complications and know when referral or specialist involvement is required.

Teaching method and workshop: Teaching methods The workshop will use a combination of brief evidence-based presentations, live demonstrations, structured hands-on practice on simulation material, small-group supervised skills stations, and facilitated peer feedback. Participants will

Expected outcomes: Participants will leave with improved procedural confidence, the ability to select appropriate techniques for common lacerations, and stronger understanding of evidence-based wound management. They will acquire transferable skills applicable across primar

Conclusion: This workshop provides a practical, interactive, and evidence-based approach to improving suturing skills in primary care. By combining updated scientific guidance with supervised procedural training, it supports safer, more consistent, and more effective wound management in everyday practice.

Albéniz LUISA, González OLGA, Cereijo ANA CLARA

Parc Sanitari Pere Virgili, Barcelona, Espagne

Context: POSTER TITLE: PARESTHETIC NEURALGIA Reason for Consultation: A 51-year-old woman presents with localized itching on her back that has been evolving over time, with a brownish skin lesion. Physical Examination: Smooth hyperpigmented area on the right scapular region with excoriation due to scratching. Altered sensation (hyperesthesia). Diagnostic Orientation: Dorsal sensory neuropathy caused by compression or irritation of the dorsal branches of the spinal nerves, manifesting as localized itching and secondary lesions. The diagnosis is usually clinical; MRI and other tests are only useful if vertebral pathology is suspected. Treatment: General measures: avoid heat, friction, and keep the skin hydrated. Topical treatment: capsaicin. Pharmacological treatment: gabapentin. Conclusions: This is an underdiagnosed condition that should be considered in patients with chronic localized itching (>6 weeks) in the scapular region and secondary hyperpigmentation due to scratching, without infiltration into primary dermatological lesions. The clinical diagnosis remains the main tool, and recognizing it early can improve patient outcomes by offering potential treatments to improve the patient's quality of life.

Methods: This article presents a primary care case of paresthetic notalgia, highlighting the diagnosis, management, and strategies to improve patient quality of life, while contributing to clinical knowledge in family medicine.

Originality: This article is original, based on observations from a clinical case

Lessons learned and future implications: This case highlights the importance of considering paresthetic notalgia in patients with chronic localized pruritus, reinforcing the value of careful clinical evaluation and timely management.

Discussion: Paresthetic notalgia is often underdiagnosed in primary care. Early recognition allows for effective management and improved patient outcomes, emphasizing the need for clinical awareness of this condition

Conclusion: This article presents a clinical case from primary care to highlight the diagnosis and management of paresthetic notalgia, a frequently underdiagnosed condition. It emphasizes recognizing chronic localized pruritus with secondary lesions, and discusses management strategies to improve patient quality of life, contributing to clinical knowledge in family medicine

ID 2213- Language barriers in Polish primary care: a national physician survey

Jung Eun YOO

Seoul National University Hospital, Seoul, Corée (République de)

Context: Obesity is a known risk factor for several cancers, but its association with gastric cancer (GC) remains inconsistent.

Objectives: We evaluated the association between metabolic–body mass index (BMI) phenotype and GC incidence in a large population, with a focus on sex and menopausal status, given hormonal influences on cancer risk.

Methods: This retrospective cohort study used data from the Korean National Health Insurance Service. We included 4,441,403 adults who underwent health screening in 2012 without a prior history of cancer. Participants were classified into four metabolic–BMI phenotypes: metabolically healthy normal weight (MHN), metabolically healthy obesity (MHO), metabolically unhealthy normal weight (MUN), and metabolically unhealthy obesity (MUO). Cox proportional hazards models were used to estimate adjusted hazard ratios (aHRs) and 95% confidence intervals (CIs) for GC risk.

Results: During a mean follow-up of 9.0 years, 32,964 individuals (0.7%) developed GC. Compared with MHN, MUN (aHR 1.04, 95% CI 1.01–1.07) and MUO (aHR 1.10, 95% CI 1.07–1.14) were associated with higher GC risk. Among males, risk increased progressively across the MHO, MUN, and MUO groups (aHR 1.16, 95% CI 1.12–1.20 for MUO). Among females, no significant associations were observed before menopause; however, postmenopausal MUO was associated with increased GC risk (aHR 1.11, 95% CI 1.05–1.18). In a sensitivity analysis with a 5-year landmark period, associations were slightly stronger. Stratified analysis showed consistent results across subgroups.

Discussion: This large-scale, nationwide cohort study of over 4.4 million Korean adults provides robust evidence that MUO and MUN are associated with an elevated risk of GC. Notably, we found this risk to be more prominent among males and postmenopausal females, underscoring the influence of metabolic health and hormonal status in GC pathogenesis.

Conclusion: Metabolic–BMI phenotype is an important predictor of GC risk. Identifying high-risk individuals—particularly males and postmenopausal females with metabolic abnormalities—may enhance prevention and screening strategies.

Context: A 36-year-old woman with no significant past medical history presents after a prolonged walk with blistering and ulcerative lesions on the toes accompanied by swelling. She reports fever and generalized malaise. Suspected skin infection with systemic involvement; therefore, the patient is referred to the hospital service

Methods: She presents leukocytosis of 24,000 and a CRP of 10. Amoxicillin/clavulanate 875/125mg is initiated. Given progression to

eschars and hypotension, septic shock is suspected and she is admitted to the ICU The skin becomes necrotic, and the CT scan shows significant fat stranding. Surgical debridement is performed under general anesthesia.

Originality: This case is original because it describes necrotizing fasciitis following a long-distance walk along the Camino de Santiago in a previously healthy young adult, highlighting an unusual trigger and presentation of a rare but life threatening condition.

Lessons learned and future implications: The importance of early recognition of necrotizing fasciitis in otherwise healthy individuals after prolonged physical activity, prompt initiation of broad-spectrum antibiotics, and rapid surgical intervention to prevent progression to septic shock.

Discussion: Necrotizing fasciitis can affect healthy individuals after minor trauma. Clinical suspicion is key, supported by imaging when necessary. Prompt treatment significantly improves outcomes..

Conclusion: Necrotizing fasciitis, although rare in healthy individuals, can occur after minor trauma from prolonged physical activity. Early recognition, timely antibiotic therapy, and urgent surgical debridement are essential to reduce morbidity and prevent fatal outcomes.

ID 1011- Leadership: Identifying stressors with a focus on self-competency assessment and resilience

Miguel VIEIRA [(1)], Maria Teresa SILVA [(2)]

(1) Nova School Of Law Of Univeristy Nova Of Lisbon, Lisbon, Portugal
(2) Faculty Of Medicine Of The Catholic University Of Portugal, Lisbon, Portugal

Context: Vitamin D deficiency is widespread globally, particularly in southern Europe including Portugal, despite abundant sunlight. Concurrently, growing evidence supports the combined use of vitamins D and K to improve calcium metabolism, skeletal integrity, and vascular health. General practitioners often prescribe vitamin D, but may overlook the co-factors needed to optimize its effect.

Objectives: To synthesize current evidence on the clinical benefits of combining vitamins D and K, and to assess prevalence and regional patterns of vitamin D deficiency with implications for preventive care in European general practice.

Methods: We reviewed peer-reviewed meta-analyses, observational studies, and clinical trials published since 2020, using databases such as PubMed and Scopus. We included studies on adult populations with emphasis on elderly and health-conscious younger adults. Topics covered include biochemical synergy, bone and cardiovascular outcomes, and regional deficiency trends.

Results: Vitamin D and K co-regulate calcium deposition: D enhances absorption while K (particularly K2) activates proteins like osteocalcin and matrix Gla protein. Combined supplementation improves bone mineral density more than D alone and may reduce vascular calcification. Vitamin D deficiency affects 47–65% of adults in Europe; rates exceed 60% in Portugal, especially in winter and among the elderly. Northern European countries often report higher D levels due to fortification. Evidence suggests young adults also show substantial deficiency due to indoor lifestyles. While D is routinely supplemented, K is rarely co-prescribed despite its mechanistic importance.

Discussion: The combined use of D and K addresses the "calcium paradox"—ensuring calcium reaches bones without damaging arteries. This synergy is particularly relevant in populations at risk for osteoporosis or cardiovascular disease. For general practice, this highlights the need for updated supplementation practices, especially in regions with high deficiency rates and aging populations.

Conclusion: General practitioners should consider co-supplementing vitamin K2 with D3 in high-risk patients, particularly in southern Europe. Targeted patient education and seasonal dosing strategies may improve long-term musculoskeletal and vascular outcomes.

ID 1411- Leading AI Responsibly in Primary Care : Exploring the Unspoken Impacts.

Stephanie DREW [(1)] , Ricky ODEDRA [(1)], Benedict HAYHOE [(2)], Ara DARZI [(1)], Ana LUISA NEVES [(2)]

(1) Institute Of Global Health Innovation, Imperial College London, St Mary's Hospital, London, Royaume-Uni
(2) Department Of Primary Care And Public Health, Imperial College London, London, Royaume-Uni

Context: Remote consultations are commonplace in primary care. However, guidance for clinicians is reportedly limited, with clinicians using 'rules of thumb' to make decisions. Previous reviews have been condition-specific or not specific to primary care.

Objectives: This scoping review aimed to identify professional guidance for primary care clinicians in OECD countries for delivering safe care via telephone and video, including guidance for specific population groups and conditions judged to be higher risk.

Methods: A grey literature search of guidance issued by professional organisations and national health bodies was carried out via targeted webpage and google searches. Documents published from 2020 onwards were considered for inclusion. One reviewer screened documents at title/abstract stage. Two independent reviewers performed full text screening and extraction. A framework developed for the planning and evaluation of remote consultation services (PERCS) was selected as a basis for extraction.

Results: Guidance from 31 documents across 12 countries and 1 international organisation (WHO) was mapped against categories relating to safety: the reason for consulting; the clinical relationship; patient factors and safeguarding. Potentially high-risk conditions were reported as inappropriate for remote consultation; whilst follow ups, chronic-disease monitoring, minor illnesses and skin conditions were appropriate. Guidance varied with respect to mental health care. Patient factors for consideration included language barriers, hearing difficulty, safeguarding and capacity concerns. The use of communication aids and presence of a support person (e.g. family member) were suggested mitigations. A pre-existing GP-patient relationship was deemed important when considering suitability.

Discussion: Guidance varied in detail but generally agreed that clinicians were responsible for determining the safety of remote consultation. This is the first scoping review exploring guidance for virtual consultations specifically for primary care within OECD countries and had no language limitations. Further advice may be available within clinical guidance for specific conditions and learning resources which were not included.

Conclusion: Findings of this review form the basis of research to improve safety and equity across patient groups. Those developing clinical guidance should ensure it is fit for purpose. Further research could look to identify gaps in guidance and explore whether any safety framework for telephone or video consultation would assist in caregiving.

ID 1012- Learning About Integrated, Person-Centered Care in Primary Health Care: Dialogues with Family Medicine

Sarah RANGEL SOULEIMANI, Beatriz OLIVEIRA GONÇALVES, Inês RAMALHO, Rita EIRIZ

Unidade Local De Saúde De Matosinhos, Matosinhos, Portugal

Context: In primary care, musculoskeletal complaints are among the most frequent reasons for consultation. While most cases reflect benign mechanical pathology, a small part may represent early manifestations of systemic autoimmune disease. Recognising warnings signs, patients health education and ensuring timely reassessment are essential roles of the family doctor.

Methods: A 63-year-old man attended an urgent consultation at a Primary Health Care Center with a 2-week history of low back and right hip pain radiating to the thigh after exertion. Examination suggested a mechanical

cause and symptomatic treatment was provided. As part of standard care, the patient was informed of the warning signs that should prompt urgent reassessment. Three days later, the patient presented to the emergency department with persistent myalgias, cervical pain, and fever. Laboratory tests revealed marked inflammatory responses, with widespread pain disproportionate to physical findings. Extensive imaging and infectious analyses showed no source. During hospitalisation, inflammatory markers rose despite empirical antibiotics. MRI of the lower limbs showed multifocal edema and autoimmune analysis revealed a strongly positive anti-Jo-1 antibody, leading to the diagnosis of antisynthetase syndrome. Corticosteroid therapy produced a rapid improvement. The patient was discharged for follow-up with Internal Medicine and Primary Health Care physicians.

Originality: Anti-synthetase syndrome is rarely first detected in primary care. Published reports describe presentations with interstitial lung disease or myositis. In contrast, this case initially mimicked common mechanical pain without respiratory involvement or elevation of muscle enzymes, which is unusual. This highlights the diagnostic challenge for physicians.

Lessons learned and future implications: Persistent or atypical musculoskeletal pain, especially with systemic symptoms, should prompt diagnostic reconsideration. Providing follow-up safety advice remains essential, as demonstrated here with clear communication of alarm signs that allowed effective patient guidance. Long-term primary-care follow-up is crucial for monitoring immunosuppression, infection prevention, comorbidity management, and patient education.

Discussion: Early recognition of red flags, appropriate escalation of care and multidisciplinary collaboration are key to improving outcomes in rare conditions that first present as seemingly routine primary-care problems.

Conclusion: This case illustrates the difficulty of identifying rare autoimmune myopathies in a clinical context largely characterized by benign musculoskeletal complaints highlighting the importance of the continuity of care and the multidisciplinary collaboration.

ID 174- Leber Hereditary Optic Neuropathy (LHON) Plus: A Case Report

Miguel VIEIRA [(1)], Maria Teresa SILVA [(2)]

(1) Nova School Of Law Of Univeristy Nova Of Lisbon, Lisbon, Portugal
(2) Faculty Of Medicine Of The Catholic University Of Portugal, Lisbon, Portugal

Context: Primary care increasingly depends on hybrid environments that integrate artificial intelligence, clinical decision-support systems, digital infrastructures, and distributed information flows. These forms of non-biological agency generate clinically relevant actions but fall outside the traditional life-centered foundations of bioethics. This results in responsibility gaps in areas such as algorithmic triage, automated alerts, digital diagnostic systems, and human–machine shared decision-making. A framework capable of grounding ethical relevance in agency rather than biological life is needed to support safer and more accountable practice in general medicine.

Objectives: This study aimed to develop and evaluate Agenoethics, a conceptual framework that grounds ethical responsibility in agency (agens) rather than life (bios). The primary objective was to assess whether this model offers clearer responsibility attribution in primary care contexts involving human, technological, and hybrid actors.

Methods: Structured conceptual analysis conducted using: - historical clinical ruptures (e.g., transplantation, IVF, genome editing) to test the limits of life-based ethical models; - philosophical analysis drawing from action theory, responsibility theory, and autonomy; - cross-domain case analysis involving artificial intelligence, digital infrastructures, and distributed decision-making in primary care; - construction of an Ethical Continuum Model tracing responsibility through decision, action,

effect, self-realisation, and reassessment; - development of two operational tools applicable to general practice: the Concentric Responsibility Map and the Responsibility Index Matrix.

Results: Findings indicate that ethical salience arises from agency with causal or probabilistic influence, regardless of whether the agent is biological. Vulnerability functions as a horizon that scales ethical weight but does not ground it. Responsibility in primary care emerges as a recursive process rather than a single event. The mapping tools identified responsibility gaps in algorithm-assisted diagnostics, telemedicine infrastructures, and distributed clinical workflows of contemporary general practice.

Discussion: Re-grounding ethics in agency clarifies responsibility relationships in environments where clinical reasoning is shared between humans and technological systems. This approach complements existing bioethical principles while addressing modern challenges such as automation, opacity, and distributed agency.

Conclusion: Agenoethics offers a coherent and operational ethical foundation for primary care in technologically mediated environments. By centering ethics on agency rather than biological life, the framework enhances accountability and supports safer and more transparent clinical practice.

ID 2302- Left Ventricular Hypertrophy Among Patients With Type 2 Diabetes: A Retrospective Analysis in a Saudi Population

Odi STUMMER [(1)] , Radlgruber ILJA [(2)], Thomas FRESE [(1)]

(1) Martin-Luther-University, Halle-Wittenberg, Allemagne
(2) Fh Wiener Neustadt, Wiener Neustadt, Autriche

Context: General practitioners frequently encounter innovative clinical solutions that could benefit significantly more patients if successfully commercialized. However, most GPs lack frameworks for translating clinical insights into sustainable revenue streams. Primary care innovation remains underutilized despite representing the majority of healthcare encounters globally. Traditional approaches focus on academic publishing rather than practical commercialization, missing opportunities to improve patient outcomes through scalable solutions. This workshop addresses the critical gap between clinical expertise and commercialization success.

Objectives: By the end of this workshop, participants will: 1. Apply the Research-to-Revenue (R2R) framework to evaluate clinical innovations for commercialization potential. 2. Master decision matrices for intellectual property protection (patent vs. trade secret), specific to healthcare settings. 3. Calculate key financial metrics (LTV/CAC ratios, NPV, rNPV) to assess venture viability using real clinical examples. 4. Navigate regulatory pathways (FDA, EMA) appropriate for primary care innovations. 5. Design actionable go-to-market strategies for healthcare solutions.

Teaching method and workshop: Welcome & Framework Introduction: 5 min Interactive Case Studies: 20 min Participants work in small groups analyzing three real clinical innovations (AI-powered diagnostic tool, digital therapeutic platform, patient engagement system). Hands-on Financ

Expected outcomes: Participants will develop practical commercialization roadmaps for healthcare innovations, including financial projections, regulatory timelines, and IP strategies. They will gain confidence in evaluating clinical opportunities, accessing funding pathways

Conclusion: This workshop bridges the gap between clinical expertise and commercialization success, enabling GPs to transform innovative patient care approaches into scalable healthcare solutions. By applying structured R2R frameworks, participants can maximize both patient impact and professional fulfillment while addressing primary care's commercialization challenges.

Linx Alexander ARANGO-SCHMITT, Bárbara OLIVÁN-BLÁZQUEZ, Angela ASENSIO-MARTÍNEZ, Alejandra AGUILAR-LATORRE, Sandra LEÓN-HERRERA, Carmen VICENTE-GARCÍA, Rosa MAGALLÓN-BOTAYA, María Del Mar MARTÍNEZ-PECHARROMÁN, Alba GALLEGO-ROYO

University Of Zaragoza, Zaragoza, Espagne

Context: In Europe, recent reports highlight a sustained rise in mental health problems, particularly depression and anxiety, over the past decade, driven by social, economic, and cultural factors such as job insecurity, inequality and loneliness. In Spain healthcare services cannot always meet the growing demand for mental health care with adequate speed or depth. This situation underscores the need for preventive, community-based, and intersectoral strategies in order to identify barriers, needs, and opportunities that are not visible in epidemiological data.

Objectives: This study aims to contribute to the co-creation of strategies that improve the prevention, early detection, and treatment of depression and anxiety in Aragón by generating context-specific knowledge to guide healthcare, educational, social, and community institutions. The general objective is to identify and analyze intervention proposals from health and education professionals, people with current or past diagnoses of depression and/or anxiety, and their families.

Methods: An exploratory qualitative study was conducted to gather the perspectives of key informants regarding potential strategies for the prevention and treatment of these conditions in Aragón. 25 participants from varied sectors (patients, family members, psychiatrists, psychologists, social workers, family doctors, nurses, educators among others) were recruited across three provinces through purposive sampling. Data was collected through semi-structured interviews on the following topics; 1) perceived differences in incidence, causation and treatment by gender, age, and social determinants of health, 2) perceived needs; 3) prevention; 4) treatment and care; 5) implementation of proposed interventions. An inductive thematic content analysis informed by grounded theory will be used and resulting intervention proposals will be assessed through a SWOT analysis.

Results: Preliminary analyses indicate recurrent concerns, including insufficient resources, limited time, and understaffing in primary care. Participants also highlighted the strong influence of social and economic determinants on mental health outcomes and on the feasibility of effective prevention and treatment strategies.

Discussion: Improving mental health in Aragón requires both better-resourced services and policies addressing structural social and economic vulnerabilities.

Conclusion: Active participation from intersectoral actors in designing intervention proposals allows for more relevant, feasible, and effective prevention and treatment of depression and anxiety in specific territories, facilitating the intersectoral coordination required for implementation.

ID 1083- Let's talk about biodiversity with patients!

Chiaki MISHIMA

Waseda Univeristy, Tokyo, Japon

Context: Urban primary care clinics increasingly encounter patients seeking cannabidiol (CBD) for sleep disturbances, anxiety, stress-related symptoms, chronic pain, and women's health concerns. CBD lies at the intersection of clinical medicine, legal regulation, product quality, public understanding, and ethics. In several East Asian settings, regulatory and quality standards are still evolving, creating uncertainty in routine clinical practice.

Objectives: To describe the real-world experience of CBD-related consultations in an urban primary care clinic and to identify patient

needs, regulatory barriers, and ethical considerations in a rapidly changing healthcare environment.

Methods: Cases were extracted from an urban primary care clinic located in a major metropolitan area in East Asia, where patients presented specifically to request CBD prescriptions or seek guidance regarding CBD use. Each case was analyzed for presenting symptoms, safety concerns, and informational needs. In parallel, domestic and international regulatory documents were reviewed to compare legal classifications, product quality standards, and levels of public literacy.

Results: The most common patient concerns were sleep disturbances, anxiety, stress-related symptoms, and women's health issues. Patients sought neutral and medically grounded explanations regarding potential benefits, risks, drug–drug interactions, and product variability. In the local context, inconsistent product standards and ongoing changes in legal classification contributed to widespread misunderstanding and safety concerns. For clinicians, the absence of standardized product testing and clear oversight mechanisms further complicated clinical judgment and risk assessment.

Discussion: CBD may offer supportive benefits for selected conditions; however, fragmented regulations, variable product quality, and limited long-term data create barriers to safe use. Differences in national health systems and cultural and ethical expectations further contribute to variation in clinical integration. Primary care physicians must carefully balance patient autonomy with safety amid commercial influences and regulatory uncertainty.

Conclusion: The integration of CBD into urban primary care requires careful attention to legal context, product quality, safety, and ethical responsibility. Primary care clinicians play a key role in providing unbiased information and supporting shared decision-making. Strengthened regulatory standards, improved product oversight, and international knowledge exchange are essential for establishing safe and equitable cannabinoid care.

ID 2303- Leveraging Explainable Machine Learning to Predict Diabetes Remission After Bariatric Surgery

Qiong FANG

Marion Urgent Care Centre, Adelaide, Australie

Context: Syncope is a brief and sudden loss of consciousness associated with loss of postural tone with spontaneous recovery. It remains a challenging presentation to primary care. Both cardiac and autonomic causes can lead to syncope. Important differential diagnoses include seizure, migraine, hypoglycemia, toxin exposure, functional disorder and nacrolepsy. In younger adults, it is often attributed to benign autonomic causes. However, life-threatening cardiac conditions may be missed, particularly in primary care where initial presentations are nonspecific. Keywords: syncope; sinus pause; Holter monitor; younger adult; primary care

Objectives: I'm presenting a case of syncope to highlight the importance of maintaining clinical vigilance for cardiac conduction disorders in middle aged patients without typical risk factors.

Methods: I will describe a clinical case and quality improvement review from a primary care–hospital collaboration. A previously healthy middle aged woman presented with recurrent syncopal episodes over one week. Initial evaluations, including clinical examinations, routine ECG, blood work, respiratory viral swab PCR, CT head, CT carotid angiogram (Circle of Willis), were unremarkable. Owing to persistence of symptoms, a 24-hour Holter monitor was arranged through primary care.

Results: 24-hour Holter monitoring revealed total of five sinus pauses ranging from 2.0-4.3 seconds with the longest pause of up to 9 seconds. The patient underwent urgent cardiology assessment and permanent pacemaker implantation at a private hospital, with complete resolution of syncopal episodes.

Discussion: Even in younger patients, cardiac conduction disorders such as sinus pause should remain an important differential diagnosis for recurrent syncopes.

Conclusion: Early use of Holter monitoring in primary care can be lifesaving and improve diagnostic efficiency through timely referral.

(1) Medication Adherence Research Center, Department Of Family Medicine, Medical University Of Lodz, Lodz, Hongrie
(2) Medication Adherence Research Group, Center For Health Technology Assessment And Pharmacoeconomic Research, University Of Pécs, Pecs, Hongrie

Context: Medication non-adherence - defined as the failure to take medicines as prescribed - remains a significant challenge in primary health care (PHC). Its consequences are wide-ranging, including poorer clinical outcomes, avoidable healthcare utilisation, increased medication waste, and substantial economic and environmental burden. Despite the availability of high-level recommendations, PHC teams often lack practical, user-friendly tools that can support the systematic integration of adherence management into routine workflows.

Objectives: To develop a concise, practice-oriented handbook that provides clinicians and other PHC professionals with actionable steps to identify, address, and monitor medication non-adherence during routine care.

Methods: This project follows a multi-phase development process informed by international collaboration. An interdisciplinary Advisory Board consisting of healthcare professionals, patient representatives, and delegates from representatives from key global professional communities including ESPACOMP was convened. The handbook structure was co-designed through iterative consultations, beginning with an initial needs assessment conducted in early 2026. Planned stages include outline development, expert review at the WONCA Europe 2026 conference, chapter drafting, targeted consultations, and final consensus approval in February 2027. The resulting content will synthesize evidence-based adherence interventions, behavioural frameworks, and feasible monitoring strategies suited to real-world PHC settings.

Results: Preliminary outputs indicate strong alignment between PHC needs and the proposed handbook. Key components include: shared decision-making and co-creation of medication plans; approaches to identifying and addressing adherence barriers; feasible adherence-enhancing interventions; practical monitoring options; and opportunities for interprofessional collaboration. The final product will be an online, freely accessible resource incorporating flowcharts, case examples, and implementation tips. Anticipated results include increased capacity of PHC teams to recognise non-adherence, improved integration of adherence support into daily practice, and reduced avoidable medication waste.

Discussion: Embedding adherence management into PHC workflows requires tools that are pragmatic, scalable, and tailored to the realities of frontline practice. International co-creation strengthens the handbook's relevance and transferability across health systems.

Conclusion: The handbook aims to provide PHC teams with clear, implementable guidance to improve adherence, enhance patient outcomes, and support more sustainable use of medicines. Its launch is planned for World Adherence Day 2027.

ID 1383- Lifestyle medicine in family practice: clarifying concepts, evidence, and training pathways

Joachim STURMBERG [(1)] , Carmel MARTIN [(2)], Kieran LE PLASTRIER [(3)]

(1) University Of Newcastle, Newcastle, Australie
(2) Monash University, Melbourne, Australie

(3) Bond University, Brsbaine, Australie

Context: Achieving an ideal primary care system – one that delivers accessible, comprehensive, and coordinated person-centred care – is a continuing priority across diverse settings. Progress is often hindered by systemic barriers such as fragmented policies, poor integration across services, workforce shortages, limited patient engagement, and inadequate data governance, which collectively perpetuate suboptimal care models.

Objectives: Identify and analyse key systemic barriers impeding the realisation of an ideal primary care system. Apply systems thinking to map interdependencies, feedback loops, and obstacles in designing an effective primary care system. Develop and propose collaborative strategies to overcome systemic barriers to advance meaningful health system reform.

Teaching method and workshop: Introductory presentation outlining the key features of an ideal primary care system and its defining attributes. Small-group system mapping exercise to explore feedback loops and interactions across critical domains such as policy, workforce, information

Expected outcomes: A deepened understanding of the complex, multi-layered systemic barriers impeding the achievement of an ideal primary care system. Acquisition of practical tools to analyse systems and to collaboratively address persistent obstacles. Development of action

Conclusion: Addressing systemic barriers demands a systemic analysis, authentic stakeholder collaboration, and adaptive policy-development. By concentrating on root causes and system-wide dynamics, participants will be empowered to transcend traditional reform approaches and pave to achieve optimal, equitable primary health care system.

(1) Department Of Family Medicine, Chungbuk National University College Of Medicine, Cheongju, Corée (République de)
(2) Department Of Family Medicine, Nowon Eulji Medical Center, Eulji University School Of Medicine, Seoul, Corée (République de)

Context: Family history represents a major inherited determinant of cardiometabolic diseases and is closely linked to shared genetic, behavioral, and environmental factors across generations. Despite its clinical importance, the impact of chronic disease family history on major adverse cardiovascular events (MACE) has not been fully characterized in large-scale Korean populations.

Objectives: This study aimed to evaluate the association between family history of chronic diseases and long-term risk of MACE using a nationally representative health screening cohort, and to determine whether family history contributes independent prognostic value beyond conventional cardiovascular risk factors.

Methods: Data were derived from 189,627 adults aged 40–65 years who underwent the 2009–2010 National Health Screening and were followed for approximately 10 years. Individuals with prior MACE, cancer, or early deaths were excluded. Multivariable Cox regression models estimated adjusted hazard ratios (aHRs) for MACE by family history of cardiovascular disease, stroke, diabetes, and hypertension.

Results: Participants with any family history exhibited a significantly higher risk of MACE (aHR 1.18, 95% CI 1.13–1.24). Among subtypes, family history of stroke (aHR 1.24, 95% CI 1.16–1.33) and hypertension (aHR 1.13, 95% CI 1.06–1.21) were significant predictors, while cardiovascular disease and diabetes histories also showed elevated trends.

Discussion: These findings indicate that family history is an independent prognostic factor for MACE, reflecting inherited susceptibility and shared lifestyle patterns that influence long-term cardiovascular outcomes.

Conclusion: Incorporating family history into cardiovascular risk assessment may enhance early identification of high-risk individuals and

support more targeted preventive strategies within the Korean population.

ID 426- Lipschütz ulcers as the first manifestation of infectious Mononucleosis

Romain VERDEAU, Aurore TRAMEÇON, Jérémy PICARD, Vincent BORGNE, Jean-Yves LE RESTE, Delphine LE GOFF, Marie BARAIS

Spurbo, Brest, France

Context: The University of XXX offers a seminar on 'training in professional relationships and communication in healthcare' for fifth-year medical students. No assessment of the benefits of this seminar on interpersonal skills and competencies has been carried out. Several studies have analysed the relationship between medical students' performance and their personality traits. The Big Five Inventory (BFI) is a validated descriptive personality scale.

Objectives: The objective of this study was to evaluate students by analysing the variation in their BFI scores.

Methods: Single-centre observational study of the before/after type conducted from 1 March 2024 to 23 June 2024. Participants in this training course completed the BFI-Fr before the session and one month after the intervention. The primary endpoint was the overall difference in scores obtained in the various personality traits for the entire study population before and after the intervention, using a Wilcoxon test.

Results: Twenty-six students were analysed. No significant difference was observed after the intervention for the personality traits 'openness to experience', 'conscientiousness', 'agreeableness' and "neuroticism". However, the 'extraversion' trait of the study population increased by 13.7% after the intervention (p = 0.007).

Discussion: Personality traits can be changed, usually through long, intensive and repeated interventions over time.

Conclusion: Here, a relatively brief intervention increases extraversion. Given the significant limitations of the study, this result should be confirmed.

Pascual DAZA-RAMIREZ [(1)] , Andrew CUPPLES [(2)], Raymond ROWAN [(3)]

(1) Gp Trainer, Nhs England, St Austell, Cornwall, Royaume-Uni
(2) Gp Trainer, Northern Ireland, Uk, Whitehead, Belfast, Ni, Royaume-Uni
(3) Gp Trainer, Republic Of Ireland, Kilkenny, Dublin, Irlande

Context: It is estimated that 18.8 million people in the UK are living with a musculoskeletal(MSK) condition. It is a major cause of morbitidy and a significant reason for presentation to primary care. MSK presentations account for a large proportion of GP workload. The prevalence is rapidly increasing with an ageing population. There is currently no structured GP curriculum for MSK common pathologies. Ultrasound(USS) performs extremely well for tendons and superficial soft tissues of shoulder, knee and wrist—often equal to or better than MRI for dynamic tendon issues. USS assessment of common MSK conditions has a significant higher diagnostic accuracy compared to clinical examination alone in conditions such as: [1]Carpal Tunnel Syndrome Based on median nerve cross-sectional area measurement. [2]De Quervain's Tenosynovitis Dynamically visualizes tendon sheath swelling and stenosing tenosynovitis. [3]Quadriceps / Patellar Tendinopathy Particularly good at showing thickening and neovascularity. 4[]Baker's Cyst Ultrasound is the preferred first-line tool. [5]Collateral Ligament Injuries [6]Joint Effusion / Synovitis Excellent for volume estimation and guiding aspiration. [7]Subacromial/Subdeltoid Bursitis Good for detecting fluid or synovial thickening. [8]Biceps Long Head Tendinopathy / Subluxation Dynamic scanning makes

ultrasound better than MRI for instability. [9]Acromioclavicular Joint Pathology

Objectives: To provide a guide to the clinical & USS assessment of common MSK conditions of the shoulder, knee and wrist in general practice

Teaching method and workshop: Session 1: Shoulder Session 2: Knee Session 3: Wrist Each session will consist of - 15 minutes audivisual lecture covering sonographic anatomy and USS image acquisition technique and examples of common pathology - 45 minutes hands- on practical demonst

Expected outcomes: Participants will gain a deeper understanding of the clinical and sonographic assessment of the common conditions [1] to [9] see context

Conclusion: It is important for GPs to perform shoulder, knee, and wrist ultrasound because it: Improves diagnostic accuracy at the point of care. Leads to quicker and more appropriate treatment. Supports safer, more accurate injections. Reduces unnecessary referrals and imaging. Enhances patient satisfaction and service efficiency. Saves costs and supports modern primary-care roles.

ID 431- Long Sleep Duration Is Associated With an Adverse Apolipoprotein Profile in Taiwanese Adults

Zeineb FOURATI, Yesmine FERIANI, Barbara MAAKAROUN, Dalenda CHERNI-GUERISSI, Lisette VOLPE-GILLOT

Pole Hospitalier Leopold Bellan, Paris, France

Context: Advance Care Planning (ACP) is essential for supporting people living with neurocognitive disorders (NCDs), whose progressive decline in communication and decision-making capacity narrows the active participation in care preferences. In France, general practitioners (GPs) are often the first to identify and follow these patients, placing them in a key position to initiate ACP. Despite this, ACP remains inconsistently implemented, and its potential benefits are underused.

Objectives: identify the main challenges, barriers, and opportunities for improving ACP for people with NCDs in general practice.

Methods: A narrative review was conducted using PubMed, Google Scholar, and French institutional sources. Publications from January 2015 to December 2024 were included if they addressed ACP, advance directives, NCDs, or general practice. Exclusion criteria were: opinion pieces without empirical basis, duplicates, and documents not addressing ACP in the context of primary care or cognitive disorders. The search used keywords as “advance care planning,” “advance directives,” “primary care,” and “neurocognitive disorders.”

Results: Twenty-one sources were included (9 scientific articles, 12 institutional documents). ACP emerged as ethically and clinically valuable, ensuring care decisions remain aligned with patients’ evolving preferences. Despite a legal framework in place since 2005, uptake is low: only 43% of French citizens know about ACP and just 18% have completed advance directives, highlighting limited awareness. GPs—key actors due to their long-term patient relationships—report insufficient training, lack of structured tools, and limited consultation time. Early, iterative ACP, initiated at diagnosis, revisited regularly, and supported by tools such as a designated healthcare proxy, appears essential to strengthen autonomy and improve end-of-life care

Discussion: Implementation of ACP in general practice is hindered by insufficient GP training, limited public awareness, and the absence of operational pathways suited to primary care constraints. Tailored ACP models are needed—ones that are feasible within GP workflows, accessible to patients, and supported by clear national guidelines and tools.

Conclusion: ACP can significantly improve care for people with NCDs. Enhancing GP training, increasing public awareness, and integrating structured ACP tools into routine practice are key priorities. Future research should assess practical, scalable ACP models suited to general practice and the progressive course of NCDs

Cs Barrio Peral, Cartagena, Espagne

Context: A 56-year-old woman comes to the clinic with multiple acrochordon-type lesions in both malar regions.

Methods: A 56-year-old woman presents with multiple skin tag-like lesions on the left side of her face, which, although already present, are now increased in size and number. The patient also reports itching in the affected area. She mentions a previous consultation with a dermatologist 15 years ago for similar, more localized lesions, which were treated with cryotherapy. The patient is of African descent. A dermatology consultation was requested via teleconsultation, with attached images. The dermatology response was: dermatosis papulosa nigra. Colleagues advise that the diagnosis is seborrheic keratoses nigra of the face, common in people of African descent—benign lesions that do not require treatment. There is a high risk of dyschromia and abnormal scarring if the lesions are removed for cosmetic purposes.

Originality: To emphasize the importance of integrating all patients in order to practice correct, effective, and fair medicine.

Lessons learned and future implications: The risk of late or incorrect diagnoses has direct implications for the patient's health. Serious pathologies such as acral melanoma, more frequent in people with dark skin, are often detected late due to their atypical presentation, which increases mortality. Conditions such as rosacea and cutaneous lupus can go unnoticed because the characteristic erythema is less visible, while genetic diseases such as sickle cell anemia and keloid formation are significantly more common in populations of African descent, reinforcing the need for a clinical approach adapted to the population.

Discussion: In dermatology, for example, the presentation of many diseases changes radically with skin color. Seborrheic dermatitis, recognized by erythema in light skin, can present as hypopigmented areas in dark skin, making diagnosis difficult. Psoriasis can manifest with purplish or grayish plaques, and post-inflammatory hyperpigmentation following acne is much more prevalent in dark skin. These clinical variations underscore that traditional diagnostic criteria and guidelines, based primarily on light-skinned patients, may not be universally applicable.

Conclusion: Traditional textbooks and many clinical guidelines primarily depict pathologies in fair-skinned individuals, which can lead to diagnostic bias. Training healthcare professionals to recognize manifestations in different ethnicities improves diagnostic accuracy and health equity.

ID 1615- Long-term Exposure to Air pollution, Gene and Chronic Obstruction Pulmonary Disease: A Genome-Wide Association Study

Carl DEANEY, Meredith DONALDSON, Agne MESKAUSIENE

Marsh Medical Practice, North Somercotes, Lincolnshire, Royaume-Uni

Context: Achieving stringent LDL-C targets is essential for reducing atherosclerotic cardiovascular disease (ASCVD) risk. ESC guidance recommends ≥50% LDL-C reduction and targets of <1.8 mmol/L (high risk) and <1.4 mmol/L (very high risk). Delivering this equitably aligns with WONCA Europe's principles of person-centred, community-oriented primary care, the NHS Long Term Plan's cardiovascular disease ambitions, and WHO priorities for non-communicable disease reduction. Inclisiran, a twice-yearly siRNA therapy targeting PCSK9, offers a simplified treatment model for patients not achieving LDL-C goals with conventional therapy.

Objectives: To assess real-world patient experience (PEx) with Inclisiran for secondary ASCVD prevention, and evaluate how implementation supports LDL-C optimisation, patient-centred care, and global primary-care priorities.

Methods: A cross-sectional mixed-methods SMS survey was distributed to 203 patients treated with Inclisiran in a rural primary-care setting (2022–2024). Eligibility required established ASCVD & persistent LDL-C elevation despite guideline-directed therapy. A total of 118 patients responded (58%). Quantitative data were analysed descriptively, while qualitative comments underwent thematic analysis & were mapped to WONCA principles (continuity, comprehensiveness, coordination, & person-centredness).

Results: Respondents were mostly ≥70 years (57.6%) and female (55.1%). Most had received Inclisiran for over one year (78.6%). Treatment acceptability was high: 93% found the injection easy to receive; side effects were infrequent (13.2%), mild, and not treatment-limiting. Overall satisfaction reached 86.7%. The majority (80.5%) preferred twice-yearly dosing to daily tablets, reflecting WHO aims to reduce treatment burden and improve adherence. Although biochemical results were not collected within this PEx survey, contemporary real-world data from the same service demonstrated LDL-C reductions of up to 59% over 27 months, supporting ESC secondary-prevention targets. Opportunities for improvement included education and involvement: 56.6% requested more information, and 23.6% felt only partly involved in decision-making.

Discussion: Inclisiran demonstrated high patient acceptance and minimal adverse effects, supporting routine implementation in primary care. The dosing schedule enhances continuity, engagement, and adherence—key components of WONCA-aligned, person-centred prevention. Gaps in patient understanding highlight the need for enhanced education, shared decision-making, & personalised lipid-lowering plans.

Conclusion: Inclisiran is a well-tolerated, convenient therapy that supports achieving stringent LDL-C targets in line with ESC & NHS cardiovascular priorities. Strengthening co-created treatment goals & patient literacy may maximise outcomes.

ID 2095- Looking Beyond The Patient: Household Risk In Herpes Zoster Management

Masja LOOGMAN, Annemarie VAN DEURSEN

Dutch College Of General Practitioners, Utrecht, Pays-Bas

Context: The COVID-19 pandemic was the most significant healthcare crisis in the past decade, placing unprecedented pressure on society and primary care. Despite the high quality of healthcare in the XXX, general practices were insufficiently prepared for such a crisis. Shortages of medical materials (e.g. personal protective equipment, medication) and the need for rapid implementation of alternative solutions (such as crisis plans, dedicated COVID clinics, remote care, and vaccination campaigns) highlighted systemic vulnerabilities. Future threats, including pandemics (e.g., avian influenza), war, cyberattacks, power outages, and climate-related disasters, remain plausible. Alarmingly, 80% of primary care physicians report being unprepared for major disruptions.

Methods: In collaboration with three key stakeholders, we developed a toolkit aligned with existing crisis structures. The toolkit aims to raise awareness and provide actionable steps for practices to prepare for emergencies. It consists of three components: Emergency Package – essential supplies for immediate response Emergency Plan – structured guidance for crisis management (first hours – days) The Good Conversation – fostering awareness and mutual support within teams

Originality: This is the first practical product in XXX designed to enhance preparedness in primary care, developed in consensus with major stakeholders. It may also be relevant and implementable for other European countries.

Lessons learned and future implications: To improve the resilience and preparedness of XXX primary care practices for future crises we develepod a practical, consensus-based toolkit with 3 key stakeholders.

Discussion: Strengths The toolkit is practical, feasible, and adaptable to all primary care practices. Dissemination will occur through established communication channels of the three national organizations, ensuring broad reach across primary care practices and primary care emergency posts. Limitations Implementation is voluntary, making uptake dependent on motivation.

Conclusion: Preparedness is essential to maintain continuity of primary care during crises. This toolkit offers practical guidance and raises awareness. However sustained attention from all stakeholders is crucial to ensure impact.

ID 661- Looking for the culprit, a case of hard "detective work" to reach the correct diagnosis

Manon REINBOLT, Angelina PACE, Betty ROULAND

Faculty Of Medicine, Strasbourg, France

Context: The French healthcare system, built on the principle of universal equality, still faces entrenched socio-cultural constructions and gender stereotypes. Medical knowledge is historically Eurocentric and male-centred, reflecting the dominant perspective of those who produced it. These biases and sexist and medical violence (SMV) significantly affect women's health pathways, widen inequalities and undermine their trust in healthcare settings.

Objectives: Qualitative: in-depth interviews, focus groups, peer groups and observational studies. Quantitative: questionnaires and statistical data on SMV

Methods: The project is a Level 2 "distributed intelligence" initiative, involving citizens in collaborative activities such as forum theatre sessions and participatory workshops alongside researchers and healthcare professionals. Based on a participatory research model, the project invites citizens to help identify environments conducive to SMV. We would conceptualise and quantify the SMV phenomenon by developing a precise definition of SMV in collaboration with multidisciplinary researchers (medicine, law, social sciences, geographic and geopolitical) and citizen co-researchers, integrating their knowledge and experiential insights.

Results: - For citizens and victims : The opportunity to express their experiences and feel less isolated. Greater recognition of their story and suffering, and the prospect of redress. Better awareness of their healthcare rights. Clearer identification of appropriate resources and support. - For victim-support services A sharper understanding of the specific nature of this violence. Development of better-suited tools and care protocols. Improved training for practitioners on these issues. - For healthcare professionals Broader public awareness of these still-taboo issues. A questioning of medical norms and practices. Progress towards a respectful and compassionate healthcare system through the engagement of public institutions and rights advocacy organizatio

Discussion: How can participative sciences in health promote knowledge and engagement in primary care system ? How can participative sciences in health help to build a network with citizens, civic society and the local healthcare system? How can citizen science projects can be used to tackle a wide range of societal challenges by engaging citizens in finding solutions ?

Conclusion: Adopting an inclusive and reciprocal approach, the project aims to share knowledge with participants, encourage mutual learning and establish spaces for dialogue and action, by incorporating citizen contributions into healthcare practices and training.

Pankaj PRASAD, Deepti DABAR, Anindo MAJUMDAR

Additional Professor, Community & Family Medicine, All India Institute Of Meidcal Sciences Bhopal, Bhopal, Inde

Context: Non-communicable diseases (NCDs) continue to cause substantial morbidity and mortality globally. Persons with disabilities (PWDs) are disproportionately affected due to limited mobility, reduced physical activity, barriers to healthcare access, and a higher prevalence of behavioral and metabolic risk factors. Understanding the determinants and distribution of NCDs among PWDs is essential for designing equitable and inclusive health interventions

Objectives: To synthesize existing evidence on the determinants, risk factors, and burden of NCDs among persons with disabilities.

Methods: This review synthesizes existing literature focusing on the epidemiology, risk factors, and prevention strategies related to NCDs among PWDs. Electronic databases

including PubMed and CINAHL were searched from inception to 26 January 2025. All non-English articles, reviews, editorials, and letters to the editor were excluded. Key terms such as “disability,” “disabled persons,” “persons with disabilities,” “non-communicable diseases,” “risk factors,” and “handicapped” were combined using appropriate Boolean operators. Titles and abstracts were screened using Rayyan software, followed by full-text review of eligible articles.

Results: The review found a consistently higher burden of NCDs among PWDs compared to the general population. Evidence indicates that 10.8% of adults with disabilities have at least one chronic condition such as diabetes, cardiovascular diseases, stroke, or cancer. Reduced physical activity, higher sedentary behavior, obesity, and structural barriers to accessing preventive and curative care emerged as major contributing factors.

Discussion: The disproportionately high prevalence of NCDs among PWDs highlights an urgent need for disability-inclusive health strategies. Current health programs often fail to accommodate functional limitations, leading to missed opportunities for screening, timely diagnosis, and management. Adaptive physical activity programs, accessible healthcare infrastructure, and targeted health education are critical to mitigating risk.

Conclusion: NCDs pose a significant yet preventable burden among persons with disabilities. A multi-dimensional approach—prioritizing accessible health services, adaptive lifestyle interventions, and inclusive public health policies—can help reduce disparities and promote better long-term outcomes.

Sungrok JEONG [(1)] , Yuna CHOI [(2)]

(1) Ppeum Global Myeongdong, Seoul, Corée (République de)
(2) Seoul Medical Center, Seoul, Corée (République de)

Context: Demand for cosmetic procedures in both primary care and aesthetic clinics continues to rise. Family physicians frequently encounter patients seeking these interventions, raising concerns about underlying mental health issues such as depression or body dysmorphic disorder (BDD). Yet, emerging evidence and clinical experience indicate that, for appropriately selected individuals, aesthetic interventions may enhance self-esteem, body image, and psychosocial functioning.

Objectives: To systematically review the impact of surgical and non-surgical cosmetic procedures on psychosocial well-being—specifically depression, anxiety, and self-esteem—and to examine how patient selection influences mental health outcomes.

Methods: A systematic review was conducted using databases including PubMed, Embase, and PsycINFO for studies published between 2004 and 2024. The review included randomized controlled trials, meta-analyses, and prospective cohort studies that assessed psychological outcomes using validated scales (e.g., FACE-Q, SF-36, SCL-90) pre- and post-procedure. Studies focusing solely on reconstructive surgery for trauma were excluded to focus on aesthetic motivations.

Results: The analysis synthesized data from key studies, including meta-analyses using FACE-Q scales. Results consistently demonstrated that successful cosmetic procedures are associated with significant improvements in body image, self-esteem, and quality of life. Specific interventions, such as botulinum toxin injections, were linked to reductions in depressive symptoms in randomized trials. Improvements in social confidence and emotional stability were most pronounced in patients who had realistic expectations and lacked severe BDD. Conversely, poor outcomes were correlated with unaddressed preoperative psychopathology.

Discussion: Findings support a shift from viewing cosmetic patients primarily as psychologically vulnerable to recognizing the potential therapeutic benefits of aesthetic interventions when provided responsibly. Minimally invasive procedures offer a relatively low-risk means of enhancing psychological well-being. However, pre-procedural mental health screening remains essential to identify contraindications, align expectations, and optimize outcomes. This approach fits well within the holistic care model of family medicine.

Conclusion: Aesthetic procedures, when offered to appropriately selected patients with realistic expectations, are associated with meaningful improvements in self-esteem, body image, depressive symptoms, and psychosocial well-being. Integrating mental health assessment and expectation management in primary care may enhance patient outcomes and support comprehensive aesthetic care.

Gergana APOSTOLOVA, Georgi PETROV, Georgi TSIGAROVSKI

Medical University Of Plovdiv, Dept Urology And General Practice, Plovdiv, Bulgarie

Context: Since the 2000 health system reform that established general practitioners (GPs) as gatekeepers, Bulgaria has faced a persistent decline in the primary care workforce. National data show a drop from approximately 4,200 GPs in 2000 to 3,700 in 2025, combined with marked ageing of the profession (73.2% over age 55). Fluctuations in the number of new GP trainees raise further concerns regarding long-term sustainability. Understanding which contractual and organisational reforms may enhance GP retention is therefore essential for strengthening primary care capacity.

Objectives: To identify feasible contractual and organisational strategies, particularly within the National Framework Contract (NFC), that could support GP retention and improve the long-term sustainability of primary care in Bulgaria.

Methods: This qualitative study was part of a broader investigation on career development in general practice. Semi-structured, vignette-based interviews were conducted with 62 GP trainees. Participants were asked to reflect on two central questions: (1) Which contractual and organisational changes could help retain GPs? and (2) How could modifications to the National Framework Contract improve long-term sustainability? Responses were provided in writing during organised training sessions. Data were analysed using qualitative content analysis to identify recurrent themes and proposed interventions.

Results: Participants (xx males, xx females; mean age xx years) proposed several near-term contractual improvements: additional remuneration for extended or atypical activities (e.g. home visits), financial mechanisms to ensure locum coverage during leave or illness, and substantial reduction of administrative burden through simplified reporting and automated electronic systems. For long-term sustainability, trainees emphasised the importance of clear reimbursement rules for telemedicine, the establishment of standards for digital health services, and stronger data-protection frameworks.

Discussion: Trainees viewed the NFC as a central policy instrument that strongly shapes working conditions, workload, and professional motivation. Their proposed changes align with broader European trends aiming to modernise primary care through digital tools, streamlined administration, and supportive workforce policies.

Conclusion: Targeted revisions to the National Framework Contract could enhance the economic and organisational attractiveness of general practice, influence career decision-making, and strengthen the long-term sustainability of primary care in Bulgaria. Implementing these measures may contribute meaningfully to mitigating the country's critical GP workforce shortage.

ID 504- Machine learning model for seborrheic dermatitis risk among patients with metabolic syndrome in primary care

Carl DEANEY

Marsh Medical Practice, North Somercotes, Lincolnshire, Royaume-Uni

Context: Ulcerative colitis (UC) requires coordinated biopsychosocial management, yet rural primary care often faces gaps in monitoring, mental-health (MH) assessment, cardiovascular disease (CVD) prevention and access to specialist IBD services. Previous local audits revealed inconsistent treat-to-target (T2T) practices, limited patient confidence in flare management and poor awareness of faecal calprotectin (FCP). Alongside this, UC is associated with elevated atherosclerotic cardiovascular disease (ASCVD) risk and substantial psychological burden, both of which may be under-recognised in real-world primary-care workflows.

Objectives: To integrate findings from four complementary evaluations—mental-health screening, ASCVD risk assessment, patient experience of monitoring and access, and a goal-directed care model—to propose an

improved, person-centred rural UC management framework aligned with WONCA, WHO and NHS long-term priorities.

Methods: A convergent mixed-methods synthesis was conducted. Retrospective UC audits captured PHQ-9/GAD-7 scores, ASCVD risk factors, lipid optimisation and LDL-cholesterol follow-up. A cross-sectional patient questionnaire explored contact with IBD teams, understanding of T2T monitoring and self-management capability. Quantitative data were summarised descriptively, while qualitative free-text underwent thematic analysis. Findings were integrated using a goal-directed paradigm emphasising safety, function, psychological wellbeing and shared decision-making.

Results: MH screening had not been previously embedded; although most recorded minimal PHQ-9/GAD-7 scores, qualitative reflections highlighted anxiety, uncertainty and social isolation. ASCVD risk was high: 67% had QRISK ≥10% and 48% ≥20%, yet fewer than half received statins and longitudinal LDL-C monitoring was incomplete. Patient-reported experience revealed low access to specialists (76% not under hospital follow-up), limited understanding of FCP and T2T principles, and low flare-management confidence. Monitoring gaps (e.g., no recent FCP tests, limited blood work) were common. Across datasets, unmet psychological, educational and cardiovascular needs were consistently observed.

Discussion: Fragmented MH assessment, suboptimal CVD prevention, monitoring inconsistencies and limited specialist access collectively hinder high-quality UC care in rural settings. A goal-directed approach provides a coherent framework to integrate clinical, psychosocial and behavioural priorities.

Conclusion: Embedding structured MH screening, ASCVD risk assessment, FCP-based T2T monitoring and shared goal-setting into routine UC reviews can enhance holistic outcomes and reduce rural health inequalities. Integrated pathways and tailored patient education are essential for effective, equitable UC management.

Context: Snakebite envenoming has been included in the list priority list of 'Neglected Tropical Disease' by World Health Organization (WHO) in 2017. It has been estimated that nearly half of the global snakebite deaths occurs in India. Limited access to timely medical care, continued reliance on traditional healing, and poor awareness of evidence-based first aid contribute to preventable morbidity and mortality.

Objectives: The primary objective was to describe the epidemiological profile and treatment-seeking patterns among snakebite victims. A secondary objective was to identify delays and barriers in accessing appropriate care.

Methods: A community-based cross-sectional study was conducted among 102 snakebite victims residing in randomly selected tribal villages. Data were collected on sociodemographic characteristics, bite circumstances, clinical manifestations, first aid practices, and care pathways using a structured questionnaire. Descriptive statistics were applied for analysis and appropriate statistical test were applied.

Results: Among 102 participants, 54% were male, and most belonged to Scheduled Tribes (93%). Young adults (22–32 years) were the most affected. Agricultural workers constituted the majority (71%), and nearly half were illiterate. Incidents were more frequent in 2024 (58%) than in 2023 (42%). Most bites occurred in fields (53%) or at home (34%),

predominantly affecting the lower limbs (60%). Only 11% could identify the snake species. Common symptoms included swelling (33%), pain with swelling (15%), and bleeding (14%); 28% reported loss of consciousness. Tourniquet use was reported in 25%. Government hospitals were the first point of care for 61%, while 35% initially visited faith healers. Among those who sought traditional care, one-third subsequently shifted to hospitals. Approximately 74% reached a health facility within one hour, and treatment initiation was immediate in 62%.

Discussion: The findings indicate persistent reliance on informal care, limited species identification, and harmful first-aid practices despite good accessibility to government hospitals.

Conclusion: Snakebite continues to pose a substantial burden among the tribals population of India. While timely transport and hospital-based antivenom therapy support favourable outcomes, delays in care-seeking and dependence on traditional practices contribute to avoidable mortality. Strengthened community education, improved early referral, and enhanced accessibility to formal care are essential. Keywords: Snake Bites; Health Behavior; Rural Population; Antivenoms; Treatment Outcome

Planetary Health Working Group Of The French College Of General Practice, Pouyastruc, France

Context: The French College of General Practitioners (CMG) has been hosting a working group on Planetary Health since 2021. This group, composed of 20 General Practicioners (GPs), is committed to creating a Planetary Health seedbox with tools for GPs and their teams. What are the 3 magic ingredients that enable this group to actively cultivate the seeds of Planetary Health and spread it all around planet earth ?

Methods: The working group is a place where experts with different skills in Planetary Health are now well identified: their role is also to link in an interdisciplinary perspective the different Planetary Health networks in France and abroad, and to initiate work and partnerships with national and international institutions. Our previous and future works include : - General awareness on Planetary Health - Perinatal care - Planetary Health diet - Organising an event respecting Planetary Health values - Eco-responsible prescribing - Integrating Planetary Health in coordinated health projects - Responding to common medical situations with a Planetary Health approach - Prescribing nature All these topics are part of the current seedbox, which keeps on growing with new topics. We are currently working on supporting Planetary Health training and research.

Originality: We propose to share the recipe for our dynamics, our values and our themes with the aim of giving an overview of our seedbox and sharing ideas and inspiration with primary care teams and other networks including european networks. Spoiler alert, you'll find just below the three magic ingredients that make our group efficient and cohesive: Awareness, teamwork, cobenefits

Lessons learned and future implications: By actively promoting Planetary Health, our group expects to inform, train and encourage people to take action : this is the role we must play if we are to meet the immense challenges posed by environmental change. The three identified ingredients of how we operate together help us to play this role.

Discussion: We limited the choice to three ingredients in order to convey a clear message. However, other key ingredients could have been chosen : sense of emergency, scientific approach, institutional support, expertise ...

Conclusion: Let's join to sow the seeds of Planetary Health all together.

ID 2282- Management of peripheral arterial disease in nonagenarian patients: beyond frailty, toward limb salvage

Sarah ROBERT, Marguerite SALABELLE, Hugo FIGONI

Sorbonne University, Paris, France

Context: Territorial health inequalities tend to worsen with the scarcity of medical provision. This scarcity varies across territories, whereas access to care should be as open as possible, especially in General Practice (GP), the entry point into the healthcare pathway. The city of XXX (Paris area) is particularly affected by this phenomenon, while its economically disadvantaged population has significant health needs. Rooted in a long history, the four municipal health centers (CMS) of this city attempt to offer the most inclusive access possible to fight against these inequalities.

Objectives: To describe the GP patient population of the XXX CMS and the territorial anchoring of these centers.

Methods: This retrospective observational cross-sectional study was conducted using administrative data extracted from the practice management software common to the four CMS in Paris area. The individual and ecological characteristics of patients who consulted at least once a GP in 2022 were described. Maps were produced to visualize the territorial anchoring of each CMS.

Results: 13,072 patients from 43,116 GP consultations were analyzed. The patient population of the XXX CMS is varied and is not limited to the city's inhabitants. More than a third of the patients possess means-tested health insurance, and more than half live in a socially very deprived neighborhood according to the FDep ecological social deprivation index.

Two types of territorial anchoring emerge depending on whether the centers are located at the crossroads of human mobility or within isolated areas.

Discussion: Being limited to administrative data, this study lacks information regarding the health status of this population. The population consulting in these centers appears more precarious than the national average. Various mechanisms, such as familiarity with the location, could explain the centers' attractiveness, notably for patients not living in the city or those who have moved away.

Conclusion: Better understanding the population consulting in GP and the territorial anchoring of the XXX CMS allows for grasping the specificities of the territories they serve, while enabling the implementation of actions aimed at reaching those who do not visit them, who are potentially excluded from care.

ID 2160- Management of selective intrauterine growth restriction in a dichorionic twin pregnancy with a bicornuate uterus: contributions of Primary Health Care

Inês RODRIGUES, Maria MARIA LÚCIA TORRES

None, Porto, Portugal

Context: Migraine is a leading cause of disability and a frequent presentation in primary care, where traditional preventives such as topiramate and propranolol remain widely used despite tolerability issues and limited adherence. Advances in migraine science have introduced calcitonin gene–related peptide (CGRP)–targeted therapies, including the oral CGRP receptor antagonist atogepant. These emerging treatments offer improved safety and convenience, positioning them as potentially transformative options within primary care.

Objectives: To summarize recent evidence on emerging preventive migraine therapies, focusing on atogepant's efficacy, safety, and clinical relevance, and to assess its potential role as a first-line option in primary care settings.

Methods: This narrative review searched for studies (meta analysis and randomized controlled trials) published on PUBMED and ELSEVIER,between 2020 and 2025. Sample sizes ranged from 252 to over 14,000 participants. Extracted data included monthly migraine day (MMD) reduction, tolerability, patient-reported outcomes, and consistency across study designs.

Results: Randomized control trials demonstrated significant reductions in MMDs with atogepant in both chronic and episodic migraine, with a favorable tolerability profile. Meta-analyses confirmed its efficacy across doses and highlighted predominantly mild gastrointestinal side effects. Long-term studies reported sustained improvements in quality of life and functional outcomes. Indirect comparison analyses suggested greater MMD reductions with atogepant than with rimegepant, reinforcing its preventive potential. Network meta-analyses also placed atogepant among the most effective and best tolerated CGRP-targeted options.

Discussion: The evidence indicates that atogepant offers advantages over traditional preventives, including simplified dosing, no titration requirements, and fewer systemic adverse effects. These characteristics support improved adherence and suitability for primary care management. Although direct comparisons with topiramate or propranolol are lacking, current data suggest that gepants are particularly valuable for patients who have not responded to or tolerated older therapies. There is a lack of cost effectiveness studies which presents an opportunity at further research.

Conclusion: CGRP-targeted therapies represent a significant advancement in migraine prevention. Evidence supports their effectiveness, tolerability, and clinical utility, making them strong candidates for incorporation into primary care migraine prevention strategies aimed at improving outcomes for individuals with migraine.

ID 855- Management of urinary tract infections in XXX: lack of benefit from audit and feedback on adherence-to-treatment guidelines.

Inês RODRIGUES, Ana ANA VERISSIMO, Inês INÊS MORAIS

None, Porto, Portugal

Context: Hypersensitivity pneumonitis (HP) is an immune-mediated interstitial lung disease triggered by repeated inhalation of organic or inorganic antigens in susceptible individuals. Its heterogeneous and often nonspecific clinical presentation contributes to diagnostic delay, which may lead to progression toward irreversible pulmonary fibrosis. This case report describes a 51-year-old factory worker involved in toy-painting, who developed non-fibrotic HP related to occupational exposure to paint vapors, that was misdiagnosed several times in urgent care highlighting the challenges of early recognition in primary care and the importance of detailed occupational history in suspected respiratory disease.

Methods: Clinical progression was documented through multiple primary care, emergency, and pulmonology evaluations over several months. Diagnostic work-up included serial chest radiographs, high-resolution computed tomography (HRCT), arterial blood gases, blood tests, pulmonary function testing, and bronchoscopy with bronchoalveolar lavage (BAL). HRCT findings revealed a centrilobular micronodular and ground-glass pattern, raising suspicion for HP. The diagnosis was ultimately supported by BAL lymphocytosis and clinical improvement after exposure cessation. Therapeutic interventions included inhaled bronchodilators, systemic corticosteroids, and occupational removal from the harmful environment.

Originality: This case illustrates an under-recognized occupational exposure scenario—paint vapors in toy-manufacturing—as a potential trigger for HP.

Lessons learned and future implications: Key lessons include the central importance of an exhaustive occupational history, early suspicion when symptoms persist despite standard therapy, and prompt referral for advanced imaging and pulmonology assessment.Clear communication with the patient regarding transmission concerns and workplace risks was also essential.

Discussion: The role of family physicians in identifying early red flags when symptoms are initially attributed to benign respiratory or gastroesophageal conditions is oftentimes key to diagnosis. The prolonged diagnostic journey in this case raises the need for heightened clinical awareness, systematic assessment of workplace exposures, and timely multidisciplinary collaboration between family medicine, pulmonology, and occupational medicine.

Conclusion: This case reinforces that early diagnosis and exposure avoidance are the cornerstone of favorable outcomes in HP. Family physicians, often the first point of contact, play a critical role in recognizing atypical or persistent respiratory symptoms and triggering appropriate multidisciplinary evaluation to prevent long-term pulmonary impairment.

Juan A LOPEZ-RODRIGUEZ

Semfyc; Universidad Rey Juan Carlos; General Ricardos Primary Healthcare Center, Barcelona, Espagne

Context: Artificial Intelligence (AI) has rapidly evolved into an essential component of contemporary medical research, offering increasingly robust capabilities to support evidence retrieval, synthesis, analysis, and scientific communication. Primary care professionals—often constrained by limited time and research support—stand to benefit substantially from AI-driven tools that streamline key stages of the research workflow.

Objectives: Demonstrate how current-generation AI tools can support literature searching, critical appraisal, statistical reasoning, and scientific writing. Compare functionalities, strengths, and limitations of updated platforms such as GPT-5, Elicit, ResearchRabbit and SciSpace and others Equip participants with practical skills to incorporate AI into their research activities ethically, efficiently, and transparently

Teaching method and workshop: Methodology: This workshop will follow a live, step-by-step demonstration of an entire research workflow—from formulating a research question to generating a draft manuscript section—using updated AI tools. Participants will interact with real-time exampl

Expected outcomes: Participants will leave with the ability to critically evaluate and effectively integrate AI tools into their own research process. They will gain practical competencies to accelerate literature reviews, strengthen methodological rigor, and improve clarit

Conclusion: By demystifying AI and demonstrating its application in real research scenarios, this workshop aims to empower family physicians to lead and participate in more efficient, evidence-based, and innovative research, ultimately enhancing the quality of primary healthcare.

Suzanne SCHAVEMAKER, Leo VAN ROSSUM, Alma VAN DE POL, Jip DE JONG

Dutch College Of General Practitioners, Utrecht, Pays-Bas

Context: Since the first Knowledge Agenda was published, new challenges and gaps have emerged, creating the need for an updated agenda. To ensure future research meets the knowledge needs of general practitioners, the Dutch College of General Practitioners (NHG) has systematically revised the agenda in close collaboration with GPs.

Objectives: Its goal is to strengthen and support general practice in the XXX.

Methods: The NHG identified knowledge gaps by formulating research questions based on 90 general practice guidelines. In addition, both individual GP's and health care stakeholders (networks and organisations) were invited to submit current knowledge questions addressing clinical and organisational issues. Clinical questions, those that arise in a individual consultation were prioritized only by GP's through an innovative online survey method measuring the relative preference of items. This Maximum-Difference (MaxDiff-) analysis asked GPs to repeatedly choose the best and worst option from a random set of 5 items. Broader organizational questions, those that arise before and after consultations were prioritized during an invitational conference with stakeholder actively shaping the future of general practice through research or policy. Many of these stakeholders also combine their roles with practicing as GP.

Results: In total, 848 research questions were identified; 115 originated from practicing GP's. After analysis 253 clinical questions and 151 organizational questions were prioritised. In total 455 GP's responded to the MaxDiff-method and 38 of the 50 stakeholders in the invitational conference were general practitioners. The prioritization process resulted in a top 50 list of clinical knowledge gaps and a top 30 list of organizational knowledge gaps. Form the 80 knowledge gaps 25 originated from individual GP's. Most knowledge gaps addressed Digital care (n=13), Cardiovascular disease (n=10), Collaboration (n=8), Personal care (7) and Respiratory system (n=6).

Discussion: In 2025, the updated XXX National Research Agenda for General Practice was published. The agenda was developed in close collaboration with many practicising GPs ensuring broad support and the process is easily copied.

Conclusion: This agenda serves as a strategic tool for researchers and research funders to focus on the most relevant and pressing knowledge gaps while avoiding duplication.

ID 11- Mapping the Factors Which Promote or Inhibit General Practitioners into Participating in Undergraduate Medical Education, A Six-Step Scoping Review.

Pedro Alejandro GONZALES FLORES, Esther OVIEDO DEL AGUILA, Kenji SILVA RABANAL, Eliana MINA QUIROGA

Mollet's Hospital., Mollet Del Vallès, Espagne

Context: A 54-year-old patient with fever treated in primary care and subsequently in an emergency department.

Methods: 54-year-old patient with history of hypertension treated with ramipril 10 mg/day. Smokes 20 cigarettes per day. Patient visits the emergency department with a fever of 38 degrees. He explains that four days earlier he experienced chest pain radiating to his back and shortness of breath. The following day he had a fever of 38.5 degrees and felt nauseous. He visited his primary care center, where he was diagnosed with a viral infection and prescribed paracetamol. In the emergency room, a fever of 38.4°C, blood pressure of 112/60 mmHg, and SpO2 of 96% are observed. Physical examination reveals no abnormalities. Laboratory tests are requested: C-reactive protein (18 mg/dL - normal value <0.5 mg/dL) and troponins (9780 pg/mL - normal value <45 pg/mL). The chest X-ray shows no abnormalities. Echocardiography showed global hypokinesia with a depressed ejection fraction (20%).

Originality: Hospital admission is decided, and as per protocol, an electrocardiogram is performed, showing ST segment elevation of 2 mm in leads DI, DII, and aVF. The on-call cardiology department at the referral hospital is contacted, and it is decided to activate the heart attack protocol in order to perform emergency cardiac catheterization for angioplasty. The result is acute obstruction of the right coronary artery by 90% with placement of two drug-eluting stents.

Lessons learned and future implications: An appropriate protocol should be followed for patients who at any time present with chest pain, i.e., performing an electrocardiogram.

Discussion: Patients with fever, chest pain, and elevated myocardial enzymes, with decreased ejection fraction, are usually consistent with myopericarditis. In this case, the symptoms and findings pointed to that diagnosis, but the electrocardiogram findings led us to consider a more urgent condition, such as acute myocardial infarction. In this case, the fever acted as a distracting factor, since the initial focus was on finding something infectious. The request for troponin testing was incidental, based on chest pain that had occurred four days earlier.

Conclusion: Electrocardiogram should be requested immediately for all patients with chest pain. Patients are dynamic, and the therapeutic approach can be modified according to findings.

ID 870- MASLD in primary care: From early recognition to lifestyle and long-term management

Abeer AHMAD [(1)], Marlous KORTEKAAS [(2)]

(1) Umc Utrecht, Amstelveen, Pays-Bas
(2) Umc Utrecht, Utrecht, Pays-Bas

Context: Cardiovascular diseases (CVD) are a major cause of morbidity and mortality. In Dutch primary care, patients with elevated cardiovascular risk are monitored through the CVRM program. Increasing workload and staff shortages in general practice threaten structured monitoring. Home monitoring may support care, but home monitoring remotely supervised by a Medical Control Center (MRC) has not yet been evaluated in primary care regarding feasibility, usability, and patient and healthcare provider satisfaction.

Objectives: To evaluate the feasabilty and usability of MRC-supported home monitoring for CVRM patients in primary care, and its impact on patient and healthcare provider satisfaction.

Methods: A prospective pilot will include 30–50 CVRM patients (18–80 years) from one

general practice. Over a three-month period, patients are asked to measure their blood pressure two times a day on five days of their choice in one week, once per month. In addition, they will be asked to answer questions regarding CVRM twice, in the first and third month. All submitted data will be reviewed by the Medical Control Center (MRC) using predefined thresholds. Outcomes include patient-reported usability (MAUQ), satisfaction, self-management, adherence with measurements (≥70% considered feasible), and the frequency of contacts the MRC and practice nurses (POH). Experiences of POH and MRC staff will be explored through qualitative interviews and analyzed using thematic content analysis. Quantitative data will be summarized descriptively.

Results: We expect this pilot (end of May 2026)to provide insights into the feasibility and usability of MRC-supported home monitoring and show that both patients and care providers are satisfied with the workflow. Adherence data will indicate practical applicability in routine primary care.

Discussion: Findings will inform whether MRC-supported home monitoring is a viable approach for CVRM care in primary care, highlighting potential benefits for patient involvement and care efficiency. Challenges such as integration into existing workflows may require attention.

Conclusion: This pilot is expected to generate evidence that MRC-supported home monitoring for CVRM is feasible, usable, enhances patient self-management, and is satisfactory for both patients and care providers, supporting broader adoption among general practitioners in primary care.

ID 2227- Maternal Mortality in São Paulo: Socioeconomic Profile and Obstetric Causes

Yasemin CAYIR, Rabia GOGERCIN, Furkan SAKIROGLU

Ataurk University, Erzurum, Türkiye

Context: Vaccine refusal has become an increasing public health challenge in Türkiye and globally, jeopardizing herd immunity and complicating the delivery of preventive services. Family physicians (FPs), frequently encounter parents who reject childhood vaccines. Understanding how FPs perceive vaccine refusal, and which strategies they employ is essential for strengthening primary care–based immunization services.

Objectives: This study aimed to explore the experiences, communication processes, and coping strategies of FPs confronted with vaccine refusal.

Methods: A qualitative phenomenological design was used. Semi-structured, in-depth interviews were conducted with FPs working in Family Health Centers in Türkiye. Interviews were audio-recorded, transcribed verbatim, and analyzed using thematic analysis with MAXQDA 24. Codes, categories, and overarching themes were developed iteratively through an inductive approach.

Results: FPs reported encountering vaccine refusal with variable frequency, most commonly driven by misinformation, religious concerns, fear of adverse effects, distrust in the health system, and social media influence. FPs employed multiple coping strategies: 1- Educational and evidence-based counseling, universally applied; 2- Empathic and patient-centered communication techniques, including motivational dialogue; 3- Pragmatic or sanction-oriented approaches in selected cases (e.g., documentation requests, repeated scheduled visits). Vaccine refusal generated emotional strain, moral distress, and workload burden among FPs. System-level gaps—such as limited consultation time, absence of standardized guidance materials, and inadequate institutional support—further complicated case management.

Discussion: This study shows that vaccine refusal in primary care is shaped by misinformation, socio-cultural factors, and limited systemic support. Although FPs frequently use evidence-based counseling and empathic communication, these strategies alone are often insufficient for changing parental decisions. The emotional and professional strain reported by physicians highlights the need for structured national guidance, improved communication training, and stronger organizational support.

Conclusion: FPs' experiences in this study show that vaccine refusal is shaped by misinformation, socio-cultural factors, and limited institutional support. Their perspectives highlight that evidence-based explanations and empathic communication help but are often insufficient to change parental decisions. According to physicians, effective management of vaccine refusal requires stronger system-level support, clearer national guidance, and enhanced training to empower primary care in this growing public health challenge.

ID 1475- Maternal obesity and overweight

Aybike KALKAN, Feyzanur ERDEM, Secil ARICA

Prof.dr.cemil Tascioglu City Hospital, Istanbul, Türkiye

Context: Family physicians frequently face heavy workload, burnout, and domestic responsibilities; however, gender- and marital-status–related differences in these areas remain insufficiently investigated in Türkiye.

Objectives: This study aimed to provide a multidimensional assessment of work–life balance, burnout, psychological safety, and household care burden, and to examine how

these domains vary by gender and marital status.

Methods: This nationwide cross-sectional survey, conducted after ethics approval, recruited physicians through online professional networks who then completed a Google Forms questionnaire covering work–life balance, burnout, psychological safety, domestic workload, and work-related characteristics. Data were analyzed using SPSS. Descriptive statistics were used to summarize participant characteristics, normality was assessed with the Shapiro–Wilk test, and appropriate comparative analyses (independent-samples t test, Mann–Whitney U, or chi-square) were applied based on variable type and distribution.Internal consistency of scales was assessed with Cronbach's alpha. Statistical significance was set at $p < 0.05$.

Results: A total of 230 family physicians participated (138 women,92 men).The mean weekly working time was 41.10 ± 9.09 hours, and the mean daily patient volume was 59.30 ± 22.55. Among participants with childcare responsibilities (n = 57), mean daily childcare duration was 376.84 ± 334.21 minutes. The mean Maslach burnout score was 4.00 ± 0.92, reflecting moderate-to-high burnout levels.Among married participants, women reported significantly longer daily housework duration than men ($p = 0.048$, $r = 0.17$).Burnout categories did not differ by gender ($p = 0.590$) but were strongly associated with marital status ($p < 0.001$). Married physicians were more frequently classified as "needs professional support". Burnout scores were significantly higher among participants who had considered leaving the profession in the past year ($p = 0.009$).

Discussion: In line with existing evidence demonstrating disproportionate domestic responsibilities among women physicians, our findings indicate that such gendered disparities become most evident within marriage, paralleling the elevated burnout patterns reported in prior research.

Conclusion: The findings indicate that although work–life balance scores were similar across demographic groups, pronounced gendered inequalities in unpaid domestic labor emerged within marriage, making marital status a key determinant of burnout severity and underscoring the need for policies that acknowledge invisible domestic labor and support the well-being of family physicians in Türkiye.

ID 2210- Maximizing Cardiorenal Protection: The Superiority of Combined Finerenone and SGLT2i Therapy

Mohamoud MERALI, John WERU, Gulnaz MOHAMOD

Aga Khan University, Nairobi, Kenya

Context: A 42-year-old man with end-stage renal disease is being evaluated for a living-donor kidney transplant. His potential donor is his 38-year-old brother. The recipient's wife has been acting as the interpreter for both men during clinic visits, as the family shares a close relationship and prefers to keep communication "within the family."

Methods: Conflict of Interest in Use of an Interpreter The wife has dual roles—interpreter and family member—creating a conflict that compromises accurate, impartial communication. Donor Autonomy and Informed Consent The donor must receive clear, complete, unbiased information about any factors that could affect the transplant outcome. Lack of transparency prevents informed consent Recipient Confidentiality vs. Donor Safety The recipient has the right to privacy, yet the transplant team also has an ethical obligation to protect the donor from foreseeable risk (risk–benefit assessment.) Family Dynamics and Undue Influence The close relationship among all parties increases the risk of emotional pressure, even unintentionally. Using a family member as interpreter can mask coercion

Originality: During the discussion privately, the wife/interpreter informs the transplant team of a significant health condition affecting the recipient—one that may influence graft outcomes and long-term survival. She insists

that this information not be disclosed to the donor, expressing concern that the brother will withdraw his offer to donate. The donor appears motivated and supported by both his brother (the recipient) and the recipient's wife. He feels well-informed and confident that he understands the medical implications of donation.

Lessons learned and future implications: Arrange a neutral interpreter to remove conflict of interest. Privately counsel the recipient about the necessity of disclosure. Ensure the donor undergoes an independent donor advocate assessment to confirm voluntariness and understanding. If the recipient refuses disclosure, the team may ethically decline to proceed with the transplant.

Discussion: This case underscores the essential role of professional interpreters, independent donor advocacy, and structured communication protocols in transplant evaluations. When informed consent cannot be guaranteed, the transplant team may be ethically obligated to pause or decline proceeding with the donation.

Conclusion: There is need for clear institutional guidelines and reinforces the central ethical principles of autonomy, transparency, and protection of donor welfare in living kidney transplantation.

ID 846- Mayer-Rokitansky-Küster-Hauser (MRKH) Syndrome: A Rare Case Report from XXX

Jungin CHOI

Department Of Family Medicine, Pusan National University Yangsan Hospital, Yangsan, Republic Of Korea, Yangsan, Corée (République de)

Context: Metabolic syndrome (MetS) is highly prevalent in Asian middle-aged adults and represents a major burden for primary care. Conventional MetS criteria do not fully capture visceral adiposity or insulin resistance, which are key components of its pathophysiology. The Metabolic Score for Visceral Fat (METS-VF) and the Metabolic Score for Insulin Resistance (METS-IR) are non-invasive indices derived from routine clinical data and may help refine metabolic risk stratification.

Objectives: To investigate genome-wide genetic associations with MetS across varying levels of METS-VF and METS-IR in a large Korean community cohort.

Methods: Data from 70,583 adults aged ≥40 years in the Korean Genome and Epidemiology Study (KoGES) were analyzed. Participants were categorized into tertiles (T1–T3) of METS-VF and METS-IR. MetS was defined using standard clinical criteria. Genome-wide logistic regression analyses were conducted within T1 and T3 of each index, adjusting for major demographic and lifestyle factors. Genome-wide significance was defined as $p < 5\times10^{-8}$.

Results: MetS prevalence rose markedly across tertiles (2.6%→79.2% for METS-IR; 5.7%→72.2% for METS-VF). The strongest and most consistent associations across strata occurred at the APOA5–ZPR1–BUD13 cluster, a key regulator of triglyceride-rich lipoprotein metabolism. Additional lipid-related loci showed context-dependent patterns: LPL variants were protective mainly in METS-VF T3; CETP variants were protective in T1; and an APOC1-proximal variant increased MetS risk only in T3. In contrast, variants near ARHGEF11 (vascular tone) and DGKB (insulin signaling) were associated with MetS primarily in the lowest tertiles of METS-VF and METS-IR.

Discussion: METS-VF offered a more biologically coherent stratification than METS-IR because it reflects visceral adiposity–driven metabolic dysfunction rather than heterogeneous systemic insulin resistance. This enabled lipid-related and context-specific genetic pathways to emerge more clearly. Importantly, METS-VF distinguished metabolic environments in which different genetic mechanisms—triglyceride metabolism, vascular regulation, or early insulin signaling—become dominant contributors to MetS. These findings suggest that visceral fat burden fundamentally shapes the penetrance of genetic risk for MetS.

Conclusion: Using METS-VF and METS-IR revealed distinct genetic pathways underlying

MetS. METS-based indices, accessible in primary care settings, may strengthen risk stratification and guide more targeted prevention strategies in community populations.

ID 957- May-Thurner syndrome with iliac vein compression, deep vein thrombosis, and pulmonary embolism; rapid diagnosis is essential. A case report.

Vincent BORGNE

Ubo, Brest, France

Context: In France, medical students training takes place primarily in hospital settings, with limited exposure to primary care professionals. Medical students choose their specialty at the end of their sixth year of study. For several years, the Faculty of Medicine in Brest has implemented a teaching seminar focused on medical practice settings and medical specialties, aimed at supporting sixth-year students in developing their professional project.

Methods: The evaluation of the teaching seminar was conducted using a questionnaire, collecting students' professional project before and after the teaching seminar. Individual interviews were then carried out with students to explore their perceptions and the impact of this teaching on their professional project, until data saturation was reached. The interviews were analyzed using Grounded theory methodology

Originality: First qualitative evaluation of this teaching seminar, including an assessment of students' perceptions of primary care practice. It will also evaluate how sixth-year medical students develop their professional project in the context of the recent reform of the second cycle of medical studies in France.

Lessons learned and future implications: The teaching seminar will be set in 2 sessions, in December 2025 and March 2026. Data collection will take place from December 2025 to April 2026. The results will be presented during the WONCA conference.

Discussion: Study Ongoing

Conclusion: This study will evaluate the influence of a teaching seminar on the professional project of french sixth-year medical students. The data collection is set to take place from Decembre 2025 to April 2026.

ID 2255- Medical education engagement in the post-pandemic era

Ting Lun WANG, Yi-Ling SHEN

Department Of Family Medicine, Taipei City Hospital Yangming Branch, Taipei, Taïwan

Context: As more regions worldwide transition into super-aged population structures, the need for robust primary care systems capable of identifying asymptomatic metabolic bone disorders has become increasingly pressing. Population-based elderly health examinations—where implemented—provide valuable opportunities for early detection, particularly through routine biochemical testing and bone mineral density (BMD) assessments. In this context, we report a case of osteoporosis likely attributable to primary hyperparathyroidism (PHPT), detected incidentally through such a screening program.

Methods: An 85-year-old woman with a history of bilateral renal stones was incidentally found to have hypercalcemia (10.8 mg/dL) and severe osteoporosis (T-score −3.9) during a population-based elderly health examination. Follow-up laboratory evaluation revealed elevated intact parathyroid hormone (97.7 pg/mL), vitamin D deficiency (16 ng/mL), and a 24-hour urinary calcium excretion of 181 mg/day with a calcium–creatinine clearance ratio of 0.013. Differential diagnoses included familial hypocalciuric hypercalcemia and secondary hyperparathyroidism. However, the overall biochemical and clinical profile supported PHPT as the leading diagnosis, with further clarification achieved after vitamin D repletion. Anti-resorptive therapy was also initiated.

Originality: This case illustrates the increasing importance of primary care in interpreting

incidental hypercalcemia identified through routine screening. It demonstrates how early detection pathways can meaningfully influence the diagnostic workup of PHPT and enable more timely management of osteoporosis.

Lessons learned and future implications: A broad and structured approach to the differential diagnosis of hypercalcemia helps elucidate the complex interactions between biochemical markers and bone metabolism. This case also raises concerns regarding cautious vitamin D supplementation—with appropriate monitoring—in patients with deficiency and a history of nephrolithiasis. In addition, it underscores the importance of initiating osteoporosis treatment promptly. Together, these insights highlight opportunities to strengthen primary care evaluation pathways and ensure timely intervention.

Discussion: As global populations continue to age, strengthening early detection strategies—such as incorporating BMD testing into routine elderly assessments—may improve fracture prevention efforts. Clear interpretation of screening results, together with streamlined decision-making algorithms, is essential to support general practitioners in the evaluation and management of metabolic bone diseases.

Conclusion: Integrated screening strategies, coupled with structured primary care follow-up, are crucial for ensuring early detection and equitable management of bone and mineral disorders in ageing societies.

ID 1534- Medical-historical study of cases of sudden death reported in newspapers in the district of Domfront (1900-1914)

Kübra EFE, Özlem SUVAK

Etlik City Hospital, Ankara, Türkiye

Context: Headache is one of the most common complaints in primary care. While most are primary headaches, changes in headache pattern, inadequate response to treatment and increased analgesic use are red-flag features suggesting secondary causes.

Methods: A 45-year-old woman presented with a one-year history of progressively worsening headaches, now occurring 4–5 times per week and waking her from sleep. Despite recent neurology evaluation and adjusted migraine prophylaxis, symptoms worsened and daily analgesic use increased. Neurological examination was normal. Due to red-flag features, she was referred to ENT for neck–carotid evaluation. CT angiography showed a 56×25 mm hypervascular mass consistent with a glomus tumor. She underwent embolization and surgical excision.

Originality: The only presenting complaint was headache, without focal neurological deficit or otologic symptoms. A rare glomus tumor was diagnosed solely through primary care clinical reasoning based on red-flag symptom recognition rather than classic tumor findings.

Lessons learned and future implications: Change in headache pattern requires re-evaluation. Analgesic overuse and failure to improve despite recent specialist assessment should prompt search for secondary causes. Family physicians play a key role in early identification and timely referral, improving outcomes.

Discussion: Paragangliomas are rare and often present with nonspecific symptoms. Early recognition of red-flag features in primary care prevented diagnostic delay and facilitated appropriate multidisciplinary management. This case emphasizes the educational value of structured decision-making in common symptoms such as headache.

Conclusion: Early recognition of red-flag features and timely referral in primary care can prevent diagnostic delay and reduce morbidity. This case highlights the critical role of family physicians in identifying secondary causes in patients presenting with common symptoms such as headache.

ID 609- Medicine as Moral Architecture: Designing a Family Medicine Department from Scratch

Silvia MASARYKOVÁ

The Slovak Society Of General Practice, Bratislava, Slovaquie

Context: Introduction: Exercise-induced vasculitis, often referred to as “Disney rash,” is a benign cutaneous small-vessel vasculitis that develops on the lower extremities after sustained physical exertion, particularly in hot or humid conditions. Although the rash may appear striking—with erythematous or purpuric, bruise-like patches—it is not dangerous and does not lead to long-term complications. The underlying mechanism involves inflammation of superficial dermal vessels, and symptoms may include mild pruritus, burning, or local discomfort. The condition is more frequently observed in women over 50 years of age and individuals who are overweight or prone to heat-related circulatory changes. -

Originality: Case Report: A 65-year-old overweight woman developed a sharply demarcated erythematous rash above the sock line during a summer hiking holiday in a mountainous region. She had been walking more than 10 km daily. On the third day she noticed the sudden onset of a mildly pruritic rash without systemic symptoms. Although still able to continue hiking, she became increasingly alarmed by the vivid appearance of the lesions. As commonly seen in patients unfamiliar with this benign entity, fear of a potentially serious condition prompted her to seek medical evaluation by her general practitioner when the rash failed to improve.

Conclusion: Conclusion: Exercise-induced vasculitis is self-limiting, typically resolving within one to two weeks. Management focuses on rest, cooling measures, leg elevation, adequate hydration, and avoidance of heat exposure. Clinically, it may be mistaken for cellulitis, contact dermatitis, insect bites, stasis dermatitis, or leukocytoclastic vasculitis; therefore, recognition of its characteristic presentation is important to prevent unnecessary treatment.

Ryuk Jun KWON, Soo Min SON

Department Of Family Medicine, Pusan National University School Of Medicine, Yangsan 50612, Republic Of Korea, Yangsan-Si, Corée (République de)

Context: Dyslipidemia is one of the most common chronic conditions managed in primary care, and long-term preventive strategies are essential to reduce both cardiovascular and cancer-related morbidity. While statins are widely used, the potential broader benefits of adding ezetimibe—particularly regarding cancer prevention—remain unclear in routine practice. As combination therapy is increasingly initiated in primary care settings, evidence on its long-term impact on cancer outcomes is needed to guide clinical decision-making.

Objectives: To evaluate whether ezetimibe–statin combination therapy is associated with a lower long-term risk of cancer compared with statin monotherapy in a real-world primary care population, and to explore potential biological mechanisms supporting this association.

Methods: A retrospective cohort study was performed using the Korean National Health Insurance Service–National Sample Cohort. Adults newly diagnosed with dyslipidemia were categorized into statin monotherapy, ezetimibe–statin combination therapy, and non-user groups. Propensity score matching was used to balance baseline characteristics. Cox proportional hazards models estimated cancer incidence, and subgroup analyses were conducted by age, sex, and diabetes status. To assess biological plausibility, Dependency Map (DepMap) analyses and in vitro proliferation assays were conducted focusing on Niemann–Pick C1-Like 1 (NPC1L1).

Results: Among 104,212 individuals, ezetimibe–statin combination therapy was associated with a substantially lower risk of overall cancer compared with statin

monotherapy (approximately 50% relative risk reduction). The association was strongest for digestive organ cancers, including liver, gastric, and gastro-esophageal cancers. Findings were consistent across sex, age, and metabolic subgroups. Experimental analyses showed reduced cancer cell viability with NPC1L1 knockdown and greater antiproliferative effects with combination therapy versus statin alone.

Discussion: Ezetimibe–statin therapy was associated with a meaningful reduction in long-term cancer incidence, with the strongest effects observed in gastrointestinal cancers. The consistency of results across subgroups and the biological plausibility supported by NPC1L1-related experimental data suggest that the benefit may extend beyond cholesterol lowering. These findings highlight the potential preventive value of combination therapy in real-world primary care settings.

Conclusion: Ezetimibe–statin therapy showed lower long-term cancer risk than statins alone, suggesting potential preventive value in primary care.

ID 364- Mentoring during the general medicine specialization pathway: an innovative and encouraging system

Jovern TEO, Lay Hoon GOH

Lee Kong Chian School Of Medicine, Singapore, Singapour

Context: Personal beliefs about control over health, Health Locus of control (HLOC), are significantly associated with health-promoting behaviours, including physical activity, smoking cessation, dietary choices, adherence to screening, and medication compliance.

Objectives: This study evaluates the impact of perceptions of health on health-seeking behaviours among low-income neighborhoods in XXX.

Methods: A cross-sectional survey was conducted amongst XXX Rental Flat residents in October 2025. A 15-question validated scale utilising 5-point Likert Scale to measure adults' perceptions of health distributed. The means of 4 subscales (Center of Control, Self-Awareness, Certainty, Importance of health). ANOVA was performed to analyse the associations with health associated behaviours. Outcomes were presented descriptively.

Results: The study comprised 116 residents (50.8% female) with a mean age of 64 (SD = 10.7). Aggregate of perspective of health survey yielded 4 subscales:Center of Control (2.90, 95%CI: 2.76-3.05) Self-Awareness (3.94, 95%CI: 3.82-4.06) Certainty (2.92, 95%CI: 2.78-3.06) Importance of Health (3.83, 95%CI: 3.70-3.95). After age adjustment, smokers with ≥20 pack-years did not differ significantly from those with <20 pack-years on any of the four health perspective subscales (all $p \geq 0.05$), although a non-significant trend toward lower Certainty scores was observed in heavier smokers ($p = 0.087$). No significant differences emerged by exercise frequency (≥3 vs. <3 times/week), presence of chronic conditions, or among those with chronic conditions - whether lifestyle changes had been made post-diagnosis (all $p > 0.05$).

Discussion: In this sample, health-related beliefs were largely unrelated to smoking intensity, exercise frequency, presence of chronic illness, or post-diagnosis lifestyle change behaviour. Limitations include small sample size, cross-sectional design, convenience sampling, and self-reporting bias.

Conclusion: In this study, health-related beliefs were largely unrelated to health-seeking behaviours. The only notable signal was a non-significant trend toward lower Certainty beliefs in heavier smokers ($p = 0.087$). Overall, these belief dimensions did not strongly drive or reflect behavioural differences in this older, low-income adult sample. Future research should use larger samples and adjust for key demographic confounders.

Pitty Serrano, 4, Panama

Context: Primary Health Care (PHC) is fundamental to achieving health equity, ensuring timely access to essential services, community participation, and addressing social determinants of health. In Panama, despite sustained economic growth and increased health expenditure in the last decade, significant disparities persist, especially among rural, indigenous, and low-income populations. A predominant allocation of resources to tertiary and quaternary care continues to undermine PHC capacity, affecting service accessibility, continuity, and quality.

Objectives: This study aims to analyze the socioeconomic barriers limiting equity in PHC in Panama, evaluating their impact on core equity indicators (availability, accessibility, acceptability, and quality) and examining territorial disparities in health resource distribution.

Methods: A comprehensive review and synthesis were conducted using three key documents focused on health inequities, social determinants, and access barriers across urban, rural, and indigenous contexts.

Results: Findings reveal that structural, financial, geographical, and organizational barriers disproportionately affect vulnerable populations. Identified limitations include institutional fragmentation between the Ministry of Health and the Social Security Fund, unequal distribution of healthcare professionals, reduced primary care capacity, high indirect patient costs, inadequate infrastructure, and recurrent shortages of medical supplies. Additionally, social determinants such as multidimensional poverty, low educational attainment, and urban centralization exacerbate inequities, directly impacting all dimensions of equity.

Discussion: These barriers compromise not only access but also the timeliness, continuity, and quality of care. Evidence suggests that increased health expenditure alone is insufficient unless accompanied by effective redistribution of resources toward primary health care and targeted policies for historically underserved areas. Strengthening PHC infrastructure, integrating care networks, and addressing underlying social determinants are essential strategies to improve equity and effectiveness, particularly in rural and indigenous territories where historical exclusion correlates with poorer health outcomes.

Conclusion: In conclusion, despite investments and economic progress, PHC in Panama remains challenged by persistent gaps in equity, coverage, and quality. Addressing these inequities requires comprehensive policies that combine resource reallocation, PHC strengthening, and interventions on social determinants, ensuring accessible, continuous, and equitable health care for all.

ID 2078- Metabolic syndrome in patients with primary aldosteronism: a retrospective study with implications for primary care

Khairat AL HABBAL

Nova Scotia Health, Halifax, Canada

Context: Social determinants of health (SDH) impact health more than biological factors. Yet, research shows a lack of training on SDH in both undergraduate and postgraduate medical education, with studies confirming that social needs of patients are not routinely identified or addressed by healthcare professionals in clinical practice. Family physicians can be involved in education at both graduate and undergraduate levels. Teaching SDH as early as the undergraduate medical years increases the chances of graduating physicians who can address the patients' needs better.

Objectives: How do you design and implement a SDH curriculum in undergraduate medical education using a home visit program led by family doctors?

Methods: The Institute of Medicine's Behavioral and Social Science Knowledge Domains were used as a framework to guide the design of the SDH program. The program was created by enhancing the didactic component with interactive workshops, adding

reflective practice training and ensuring that the family physicians' home visit program becomes a longitudinal experiential program that integrates medical home visits with social activities in collaboration with community partners.

Results: Student surveys, reflective essay analysis, and reflection on the experiential program facilitate by faculty all showed an increased awareness of SDH and increased readiness to address them.

Discussion: Home visit programs led by family doctors can be transformed into powerful tools to educate about SDH. Pairing them with some interactive workshops, reflective practice and partnerships with the community enhances the outcomes.

Conclusion: Building on family medicine home visit programs can increase students' awareness of SDH.

ID 1669- Metabolic Syndrome in Type 1 Diabetes: Prevalence, Glycemic Control, and Therapeutic Implications

Cecilia AMERICO DE ALMEIDA MARTINS, Fernanda TELES LEIRO, Erica SANTOS BARBOSA, Maria Fernanda ERNESTO SILVA QUARESMA, Maria Clara PEREIRA RAMOS, Rafael MESQUITA BERNARDES

Centro Universitário De Brasília, Brasília, Brésil

Context: Humanized care has become a critical component of chronic disease management in Primary Health Care, where patients value empathy, active listening, and shared decision-making as much as technical expertise. Fragmented communication, limited continuity, and insufficient attention to patients' experiences undermine engagement and self-management. In contrast, person-centered approaches integrating psychological and social dimensions strengthen clinical effectiveness, adherence, and perceived quality of care.

Objectives: To evaluate how humanized and person-centered approaches in Primary Health Care influence biological, psychological, and social outcomes among individuals living with chronic diseases and multimorbidity.

Methods: A systematic search was conducted in PubMed, LILACS/BVS, and the Cochrane Library for studies published in the last five years. MeSH terms related to Primary Health Care, Chronic Disease, Multimorbidity, Self-Management, Quality of Life, and Psychological Stress were combined with Boolean operators (AND/OR). Systematic reviews and meta-analyses were excluded. Eligible studies evaluated humanized or person-centered interventions versus standard care and reported biological, psychological, or social outcomes. Four reviewers independently screened all records and extracted data. Given methodological heterogeneity, findings were synthesized narratively.

Results: Across diverse settings, humanized interventions improved health-related quality of life, symptom burden, and key clinical parameters, while reducing avoidable hospitalisations and healthcare costs. Psychological benefits included decreased anxiety and depression, enhanced activation, and improved self-management capacity. Social outcomes, such as trust, perceived respect, communication quality, and cultural sensitivity, were central determinants of adherence and continuity. Inequities in age, gender, education, and social vulnerability influenced care experiences, highlighting the role of social determinants in moderating outcomes.

Discussion: Humanized care functions as a relational and organizational strategy that strengthens chronic disease management by integrating empathy, communication, cultural competence, and attention to socioeconomic contexts. Benefits are amplified when supported by stable therapeutic bonds, structured education, and person-centered planning. However, structural barriers, such as limited consultation time, fragmented communication, and organizational rigidity, continue to restrict implementation.

Conclusion: Humanized and integrated care approaches generate meaningful biopsychosocial improvements for individuals

with chronic conditions in Primary Health Care. By enhancing clinical parameters, psychological resilience, and social well-being, person-centered care should be incorporated as a foundational component of routine practice and health system planning.

Context: Low CD4 counts at first presentation remain a significant indicator of delayed HIV diagnosis and increased risk of adverse outcomes. Early identification of patients at risk for late presentation is essential for improving diagnosis, linking individuals to timely treatment and guiding targeted public health interventions.

Objectives: This study aims to determine sociodemographic, behavioural and clinical characteristics associated with baseline CD4 counts <200 cells/µL among newly diagnosed HIV patients attending a primary care clinic in Bintulu.

Methods: A retrospective analysis was conducted among HIV-positive individuals who received care between 2020 and 2024. Data were extracted from medical records using a standardized form, including age, gender, ethnicity, body mass index, sexual orientation, clinical presentation, and baseline CD4 count. Patients with incomplete baseline information were excluded. Descriptive statistics summarized demographic and clinical characteristics. Univariable logistic regression was used to identify potential predictors, followed by multivariable logistic regression to determine independent associations with low CD4 count, reported as adjusted odds ratios with 95% confidence intervals.

Results: A total of 194 records were included. The mean age was 29.6 ± 6.3 years, with the majority aged 21–30 years (57.2%) and male (90%). Most patients had normal BMI (55.7%), 25.3% were overweight and 8.5% underweight. Ethnic distribution showed 56.7% Iban, 27.4% Malay and 10.3% Chinese. More than half (55.2%) identified as homosexual and 41.2% reported multiple sexual partners. Clinically, 39.6% were asymptomatic, 31% were screened due to other STIs, 25.3% presented with general symptoms and 4.7% had opportunistic infections. Overall, 40.7% had baseline CD4 <200 cells/µL. Univariable analysis identified age 21–30 years, Iban ethicity, general symptoms and opportunistic infections as associated with low CD4 count. Multivariable analysis confirmed general symptoms and opportunistic infections as independent predictors.

Discussion: These findings align with global evidence showing that symptomatic presentation and opportunistic infections strongly predict late HIV diagnosis (UNAIDS, 2023; WHO, 2022; Cohen et al., 2016). The high proportion of advanced disease underscores persistent delays in testing among young MSM populations.

Conclusion: HIV-related symptoms and opportunistic infections were strong independent predictors of low baseline CD4 counts. Strengthening early testing, targeted outreach and community awareness is essential to reduce late presentation and improve clinical outcomes.

Grupo Hospitalar Conceição-Ghc, Porto Alegre-Rio Grande Do Sul, Brésil

Context: Continuing Education in Health contributes to the organization of services, qualification, and transformation of health practices. The interprofessional Working Group (WG) for the Care of People with Chronic Conditions, promotes training activities aimed at qualifying professionals in Primary Health Care (PHC).

Objectives: To train physicians on the pharmacological management of Diabetes mellitus (DM), with an updated theoretical framework and applicability in the clinical practice of PHC.

Methods: A face-to-face training course was developed for PHC physicians, integrating the institutional continuing education program. It was based on a Guide to the Care of People with Systemic Arterial Hypertension and Type 2 DM in PHC, developed by the WG and updated according to the clinical guidelines published in 2025. Each edition of the course lasted 8 hours, divided into 2 meetings of 4 hours each, with a 30-day interval. For the first meeting, a clinical consultation was chosen focusing on oral antidiabetic drugs, cardiovascular risk stratification, and dyslipidemia. The second meeting addressed insulin administration. Team-Based Learning and a commented clinical case were used. Random division into 5 subgroups occurred in the first meeting and by affinity in the following, where questions regarding medication management were answered. Consensus on answers was established in the large group discussion and feedback was based on the Guide. Training was provided on glycemic adjustments and handling of insulin delivery devices. Information was gathered regarding the supply chain. A form was completed indicating suggestions and impacts on future practice.

Results: There were 102 participants. The questionnaire responses highlighted the relevance of the course as a qualifier for professional practice; they contributed to improving the methodology for the second meeting and reinforced the importance of the Guide as a reference point for the technical debate. The comparison of the course editions confirmed its reproducibility.

Discussion: Replicable educational interventions, with a systematized theoretical framework aligned with the best scientific evidence, contribute to standardizing practices and strengthening clinical practice in PHC.

Conclusion: Continuing education makes it possible to improve care processes in chronic diseases. The simultaneous replication of the course, the clinical discussions and the analysis of the questionnaire responses consolidate the reproducibility for future training.

ID 951- Migraine Revisited: New Frontiers in Primary Care

Wan-Yi SHEN

Family Medicine Department, China Medical University Hospital, Taiwan, Taichung, Taïwan

Context: Tonsillitis is routinely managed in primary care, yet immunosuppressed patients may present with atypical or persistent symptoms that demand closer attention. Methotrexate, widely used for rheumatoid arthritis, predisposes patients to iatrogenic immunodeficiency–associated lymphoproliferative disorders (IA-LPDs), particularly Epstein–Barr virus–positive forms. For family physicians, recognizing when a common complaint deviates from its usual course is essential to prevent diagnostic delay.

Methods: A 70-year-old woman with seropositive rheumatoid arthritis on long-term methotrexate presented with two months of recurrent sore throat and fever initially resembling bacterial tonsillitis. Examination showed erythematous tonsils with purulent exudate, and CT revealed bilateral tonsillar necrosis with extensive necrotic lymphadenopathy in the cervical, mediastinal, and axillary regions. She was referred to otolaryngolotist for operative evaluation. Bilateral tonsillectomy was performed due to concern for malignancy or deep infection. Histopathology demonstrated a polymorphic EBV-positive lymphoproliferative disorder with

Hodgkin-like features, consistent with IA-LPD. Despite delayed wound healing and persistent ulceration, withdrawal of methotrexate led to gradual and complete clinical improvement.

Originality: Bilateral necrotic tonsillitis as the initial manifestation of methotrexate-associated EBV-positive IA-LPD is extremely rare. This case broadens the recognized clinical spectrum of IA-LPDs and highlights diagnostic challenges in primary care.

Lessons learned and future implications: Persistent tonsillar necrosis, unusual lymphadenopathy, or poor response to standard therapy in immunosuppressed patients should prompt early imaging and referral. Withdrawal of methotrexate may induce complete regression in EBV-positive IA-LPDs, reinforcing the value of timely recognition in primary care.

Discussion: Although tonsillectomy provided a definitive diagnosis, image-guided core needle or lymph node biopsy could be considered as less invasive alternatives when LPD is suspected. Necrotic tonsils and widespread lymphadenopathy initially mimicked infection, delaying recognition of methotrexate-related EBV-positive IA-LPD. The absence of EBV viral load and clonality testing limits further classification, and the long-term recurrence risk remains uncertain.

Conclusion: Persistent tonsillar necrosis or atypical lymphadenopathy in immunosuppressed patients should prompt early imaging and specialist referral. Clinicians should consider IA-LPD in methotrexate-treated patients, as timely cessation of immunosuppression may allow full remission and prevent overtreatment.

ID 1416- Mobilising the next generation: strategies to foster the engagement of young general practitioners

Youn HUH [(1)], Kim YOUNG SIK [(2)]

(1) Uijeongbu Eulji Medical Center, Gyeonggi-Do, Corée (République de)

(2) Asan Medical Center, Seoul, Corée (République de)

Context: Words spoken by healthcare providers can have a profound psychological impact on patients, especially those with mental health concerns.

Objectives: Few studies have explored how patients perceive comforting or hurtful language in adults. This study aimed to identify patients' perceptions of commonly used expressions and to compare differences according to depression status, gender, and age.

Methods: A cross-sectional online survey was conducted among 1,195 adult respondents in Korea. Participants were asked to rate 15 phrases frequently used in clinical or everyday communication on a 4-point Likert scale (1 = very hurtful, 4 = very comforting). Demographic and mental health data were collected, including self-reported depression status and prior psychiatric treatment experience.

Results: Overall, participants rated most expressions as comforting rather than hurtful, with mean scores ranging from 3.1 to 3.3. The most comforting phrase was "I'm ready to listen whenever you want to talk" (mean = 3.2), while "Don't feel guilty, it's not your fault" also scored highly (mean = 3.18). Approximately 85–90% of participants classified these phrases as comforting. Differences according to depression status, gender, and age will be further presented, highlighting how personal background may shape sensitivity to certain expressions.

Discussion: Korean primary care patients generally perceive empathetic and supportive language positively.

Conclusion: Understanding which expressions provide comfort versus distress can help family physicians communicate more effectively and promote emotional healing in clinical encounters.

ID 808- Models of care in Primary Care in providing healthcare to transgender population

Lacey ANG [(1)] , Lay Hoon GOH [(2)]

(1) Nus Yong Loo Lin School Of Medicine, Singapore, Singapour
(2) National University Health System, Singapore, Singapour

Context: Singapore's mixed-payer health system places significant responsibility on individuals to adopt positive health behaviours. Recent HealthierSG (HSG) and Screen for Life (SFL) initiatives illustrate preventive-care as a core tenet of Singapore's health policy framework. While awareness is traditionally an antecedent in health-behaviour models, its differential impact across distinct "awareness levels", and how this translates into preventive-care uptake, remains poorly characterised, particularly among socioeconomically disadvantaged rental-flat communities where contextual factors complicate engagement.

Objectives: This study (1) examines patterns of screening uptake, (2) evaluates how distinct levels of awareness differentiate screening behaviour, and (3) characterises reasons for non-uptake in a Singapore rental-flat community.

Methods: A cross-sectional analysis of 120 rental-flat-dwelling adults aged ≥45 was conducted at a community health screening. Participants self-reported awareness at two tiers: basic programme recognition and actionable awareness (understanding of subsidies, eligibility and enrolment) and HSG and SFL enrolment. Data were summarised with descriptive statistics. Associations were analysed with logistic regression. Qualitative responses were thematically grouped.

Results: Participants (mean age 63.7 (±10.8); 52.5% female) had 25.0% and 31.7% enrolment rates in HSG and SFL respectively. Basic awareness was not significantly associated with screening uptake (HSG: p=0.058; aOR=1.38; 95%CI 0.99-1.90 and SFL: p=0.785; aOR=1.09; 95%CI 0.58-2.05). Conversely, actionable awareness significantly predicted uptake (HSG: p=0.003; aOR=3.15; 95%CI 1.49-6.65 and SFL: p=0.043; aOR=1.35; 95%CI 1.10-1.80). Demographic covariates showed no statistical significance. 94 participants provided qualitative responses, commonly citing lack of awareness or procedural understanding (31.9%), absence of symptoms or ambivalence towards preventive-care (27.7%) and lack of time (13.8%) as barriers. Other reasons included cost and fear of adverse results.

Discussion: This study illustrates a literacy threshold, where actionable (rather than basic) awareness drives uptake, aligning with the established Precaution Adoption Process Model. Individuals may understand the existence of a programme, yet lack ability to navigate its procedural aspects. Such process-level gaps inadvertently widen inequities in rental-flat communities who already face other barriers, in particular, reduced health literacy, revealed in responses such as "absence of symptoms", which demonstrates insufficient understanding of preventive-care principles.

Conclusion: Strengthening process-level literacies through context-sensitive support and intentional communication tools is vital to ensuring informed screening participation, and equity in Singapore's care landscape.

ID 1745- Moderate acute pain in the emergency department: comparison of the efficacy of oral and intravenous paracetamol

Anna LEE

Korea University Ansan-Si, Ansan-Si, Corée (République de)

Context: Previous studies have suggested that obesity is associated with an increased risk of developing pancreatic cancer. However, it is unclear whether the association between body mass index (BMI) and the risk of pancreatic cancer differs by glycemic status.

Objectives: This study investigated how the association between BMI and pancreatic cancer differs by glycemic status.

Methods: This Nationwide cohort study included 9,520,629 adults who underwent the

Korean National Health Screening in 2009 and were followed until 2018. BMI was divided into underweight (BMI, <18.5 mg/dL), normal (BMI, 18.5-22.9 mg/dL), overweight (BMI, 23-24.9 mg/dL), obesity stage I (BMI, 25-29.9 mg/dL), and obesity stage II (BMI, ≥35 mg/dL). Multivariable Cox proportional hazard models were used to estimate Hazard Ratios (HRs) and 95% confidence intervals (CIs) after adjusting for potential confounders.

Results: During the 78.4 million person-years of follow-up, 15,245 people were newly diagnosed with pancreatic cancer. In the normoglycemia group and impaired fasting glucose (IFG) group, even being overweight was associated with an increased risk of pancreatic cancer; HR 1.11, 95% CI 1.05-1.18, and HR 1.15, 95% CI 1.16-1.24, respectively. In both groups, the risk of pancreatic cancer was the highest in obesity stage II; HR 1.25, 95% CI 1.08-1.44 and HR 1.31, 95% CI 1.12-1.53, respectively. Among individuals with diabetes, the risk of pancreatic cancer was highest in those who were underweight, although the difference was not statistically significant; HR, 1.15, 95% CI 0.89-1.49.

Discussion: This study found that being overweight, as well as obese, increases pancreatic cancer risk in people with normoglycemia or impaired fasting glucose. In contrast, among people with diabetes, being underweight was linked to the highest cancer risk. These contrasting associations suggest different underlying mechanisms: metabolic factors tied to excess weight may drive cancer in normoglycemic or prediabetic individuals, while unintended weight loss in diabetes could indicate early or existing cancer.

Conclusion: Our findings highlight the need for individualized risk assessment and surveillance, rather than a one-size-fits-all screening approach, to improve pancreatic cancer prevention and early diagnosis efforts.

ID 1962- Moderate-to-high fatigue severity as an independent correlate of muscle strength and endurance among Hospital Employees

Emilly BARBOZA RASMUSSEN [1] , Cely CAROLYNE PONTES MORCERF [2], João MAZZONCINI DE AZEVEDO MARQUES [2]

(1) Usp, Americana, Brésil
(2) University of São Paulo, Americana, Brésil

Context: According to the World Health Organization, the preferred model for organizing health systems is People-Centred Integrated Care (PCIC), in which Primary Health Care (PHC) plays a central role. In Brazil, the Ministry of Health identifies the Family Health Strategy (FHS) as the preferred model for delivering PCIC. However, multiprofessional and transdisciplinary undergraduate education within high-quality FHS services—guided by trained professionals and team-based PCIC—is still far less common than training in hospital or specialized outpatient settings.

Methods: Undergraduate students from the University of São Paulo, spent one year immersed in a PHC unit with four family health teams. The unit, managed by the FMRP-USP/HCFMRP-USP academic health complex, covers a territory of roughly 12,000 socially vulnerable residents. Students received an initial transdisciplinary theoretical foundation on PCIC and subsequently followed family physicians in their daily activities.

Originality: The project offered longitudinal, hands-on exposure to real PCIC practice within an academically managed PHC service. It enabled students to critically examine how family medicine operationalizes integrated, person-centred care in vulnerable territories, highlighting nuances rarely addressed in traditional hospital-based training.

Lessons learned and future implications: Interviews and clinical observations revealed the complexity of caring for vulnerable patients—especially older adults—who often face multimorbidity, economic hardship, limited education, isolation, and fragile support networks. Students learned that effective care requires understanding the person's life story,

context, and functionality. They also identified the unequal distribution of chronic diseases across social groups and the centrality of person-centred rather than disease-centred approaches.

Discussion: Throughout the year, students deepened their theoretical and practical understanding of PHC and family medicine. They recognized that family medicine is essential for: ensuring universal access grounded in the person, family, and community; coordinating longitudinal care across services and levels of the health system; enabling comprehensive care through multiprofessional teamwork.

Conclusion: The project strengthened students' humanistic and integrative training in health care. It fostered transdisciplinary learning spaces focused on value-based care, person-centred clinical method, interprofessionality, integration of public and family health, health promotion, prevention, rehabilitation, palliative care, avoidance of iatrogenesis, and the interplay of biological, psychological, social, and relational dimensions, including clinical communication and motivational interviewing.

ID 1195- Monitoring Hypertension in Primary Care: Population Characterization and Care Challenges

Emilly BARBOZA RASMUSSEN [(1)] , Cely CAROLYNE PONTES MORCERF [(2)], João MAZZONCINI DE AZEVEDO MARQUES [(2)]

(1) Usp, Americana, Brésil
(2) University of São Paulo, Americana, Brésil

Context: Brazil's Migration Law represents progress in humanitarian reception and has advanced through the Solidarity Resettlement Program, prioritizing vulnerable groups in partnership with civil society. Nevertheless, refugees continue to encounter discrimination and limited access to autonomy-building opportunities. This work reports the experience of a health-care student in a teaching-and-extension project under family medicine tutoring, examining how social determinants shape the vulnerability of refugees in Brazil and highlighting primary care as a human-rights-based entry point to community health.

Methods: Experience report from a teaching and extension project addressing neglected populations for undergraduate health students. One pedagogical axis focused on theoretical and practical training on migration, refugee health, and human rights. The study was co-constructed by a student and family physicians, examining gaps that hinder effective reception of refugees in Brazil. It proposes practical strategies for confronting systemic barriers and reframing public health management to address the roots of persistent neglect beyond theoretical ideals.

Originality: Over six months, students engaged in theoretical classes and weekly article discussions on migration, refugee health, and the health system challenges.

Lessons learned and future implications: Primary care emerged as a strategic space to identify and map migrant populations, requiring flexibility beyond rigid territorial logic. Community leaders can facilitate access and registration. Persistent institutional resistance underscores the need for reinforced training in migrant and refugee health during undergraduate education and ongoing professional development.

Discussion: Over six months, students engaged in theoretical classes and weekly article discussions on migration, refugee health, and the health system challenges. Four undergraduates (three in medicine, one in speech therapy) participated in hybrid meetings and field activities. Topics included geopolitics of migration, refugee rights, primary care challenges, and barriers faced by migrant women, children, and Indigenous refugees. Field immersion revealed linguistic barriers, lack of cultural competence, limited professional knowledge of refugee family dynamics, and insufficient preparation of primary care teams for equitable, longitudinal care.

Conclusion: Primary care must act as an adaptive, equity-driven level of care capable of

responding to contemporary migratory flows. Despite limitations, it holds significant potential to reduce gaps, provided that training on migrants and neglected populations is expanded within health curricula and family and community medicine practice.

ID 1189- Mortality, and survival rates following lower limb amputation, a national observational cohort study in Sweden

Elissa PALMER

Kirk Kerkorian School Of Medicine At Unlv, Las Vegas, États-Unis

Context: Aims: (1) Determine physician stressors (2) Define issues related to gender (3) Delineate gaps in personal leadership and resilience competencies (4) Compare evidence based techniques, tools, and resources to create a personal action plan for personal professional development to enhance leadership skills and counter burnout

Methods: Methods: Interactive discussion provides a framework of the current literature with individual and group exercises to identify gaps in personal leadership and resilience competencies followed by action plan development.

Originality: Attendee engagement: Interactive discussion provides a framework of the current literature. A series of individual and group exercises will assist participants to identify their own personal gaps in leadership skills and resilience competencies. Pair-sharing and group sharing discussions will occur. Particpants will create a personal action plan with suggested evidence based resources to assist in professional skill development around leadership and prevention of burnout.

Lessons learned and future implications: At the conclusion of this presentation, attendees will be able to: 1.Explain the current evidence demonstrating gender discrepancies in leadership and risk for burnout 2.Complete assessment of personal leadership skill and resilience gaps 3.Implement the developed personal action plan for leadership and resilience

Discussion: Background: Stress, emotional distress, or burnout can affect a physician's ability to provide high-quality care. The Commonwealth Fund International Health Policy Survey of Primary Care Physicians showed that the majority of physicians in the 10 high-income countries surveyed revealed increasing physician burnout since the COVID-19 pandemic. Demographics of young age, female gender, long hours and poor job satisfaction increase risk for burnout. Compounding this, the literature suggests that women may experience a number of gender-related individual challenges that impact their path to leadership, including gender differences in approaches to career and life goals. The underrepresentation of women in leadership positions worldwide in industry and medicine continues even though the proportion of women in the workplace has increased

Conclusion: Conclusions: Creating personal action plans for leadership and resilience assist in stress prevention which is more beneficial than treatment since once burnout occurs, there is limited evidence to support modalities for resolution.

Context: Background Impact of Diabetes in Chronic degenerative disc disease is well known in the literature. We noted excessive use of opiates among poorly controlled diabetes with chronic lumbar disc disease. the aim to study the impact of lifestyle intervention

Methods: 97 females, aged [55 -70] over 24 months periods were reviewed. 60 were given lifestyle interventions included diet, exercise by MSK physiotherapist, and counselling and opiate decelerating regimes. 37 patients were already on polypharmacy. These patients were followed up by other clinicians and continued medication as per their clinician's advice Outcomes evaluated with Oswestry back pain questionnaires included reduction of opiate use, HBA1c.

Originality: Observational study

Lessons learned and future implications: The Lifestyle intervention group showed drop in HBA1c 78 to 67. and reported less radicular symptoms. All components of the pharmacologic therapy were explored. 5/60 patients did not use any opiate after one year of lifestyle intervention. 2/60 patient had HBA1c dropped to prediabetic range. There was a trend toward better weight management at 6 months in the lifestyle group. 11/37 patients required Pain injection therapy by specialist for Chronic low back pain

Discussion: Lifestyle changes produce better glycemic control, lesser use of opiates and weight management. This comprehensive medical approach that encompasses intensive lifestyle modification including behavioural changes towards nutrition, and physical activity, as well as pharmacotherapy leads to better outcome in poorly controlled diabetes with Degenerative disc disease

Conclusion: This study highlights glycemic control rather than pain medication would reduced morbidities in poor control diabetics with Disc disease.

ID 2106- Multidisciplinary Academic Research in Family Medicine: A Literature Review

Ana Gabriela HUARACHI GUARACHI, Aniela RAMÍREZ LA PUENTE

Hospital Universitario De Móstoles, Madrid, Espagne

Context: Diffuse Idiopathic Interstitial Lung Disease (ILD) is a respiratory condition characterized by inflammation and/or fibrosis of the alveolar interstitium. Its diagnosis is particularly challenging in early stages and in patients without significant respiratory symptoms. Differential diagnosis with more common chronic lung diseases such as Chronic Obstructive Pulmonary Disease (COPD) and asthma is essential. Primary Care plays a pivotal role in early suspicion and timely referral, ensuring equitable access to diagnosis and comprehensive patient management.

Methods: Un hombre de 69 años, exfumador, presentó disnea progresiva, malestar general, palpitaciones y ansiedad tras iniciar tratamiento con cilostazol por insuficiencia venosa. En la exploración física, se detectaron hipocratismo digital y crepitaciones bibasales tipo velcro. En la consulta de AP, se solicitó lo siguiente: Radiografía de tórax que muestra compromiso pulmonar periférico, sugestivo de EPI. Espirometría con patrón restrictivo. Tomografía computarizada de tórax con hallazgos sugestivos de compromiso pulmonar intersticial inespecífico. Tras la derivación, la broncoscopia reveló microbiología positiva para Serratia marcescens, tratada con trimetoprima-sulfametoxazol, mientras que la anatomía patológica fue negativa para malignidad. Se estableció un seguimiento compartido entre Neumología y AP.

Originality: Este caso destaca el papel proactivo del médico de familia en la detección inicial, la derivación oportuna y el seguimiento integral. Esto previene la detección hospitalaria tardía y los retrasos diagnósticos, que tradicionalmente superan los 12 meses. La farmacovigilancia activa en CP es esencial, ya que permite identificar precozmente la neumonitis inducida por fármacos y prevenir la progresión a fibrosis.

Lessons learned and future implications: La Atención Primaria puede acortar los retrasos diagnósticos en la EIP. La farmacovigilancia activa es crucial para detectar la neumonitis inducida por fármacos. La educación y el empoderamiento del paciente con respecto a las señales de advertencia y las vías de atención de urgencia mejoran los resultados.

Discussion: Este caso ilustra cómo la Atención Primaria puede ser la piedra angular del manejo de las EPI, garantizando la equidad y la accesibilidad al diagnóstico. La colaboración entre los niveles de atención promueve la libertad clínica responsable y una precaución diagnóstica equilibrada.

Conclusion: La Atención Primaria desempeña un papel crucial en la detección temprana de la EPI, garantizando la equidad y la accesibilidad al diagnóstico. Fomenta la colaboración entre profesionales y entre los diferentes niveles de atención, promoviendo la libertad clínica responsable y una precaución diagnóstica equilibrada. La educación y el empoderamiento del paciente respecto a su enfermedad son fundamentales, incluyendo información sobre signos de alerta, hábitos de vida y cuándo buscar atención urgente. Sólo a través de esta fraternidad asistencial y de una práctica clínica profundamente arraigada en la humanidad, la Atención Primaria puede garantizar la equidad diagnóstica y convertirse en la verdadera piedra angular para el manejo integral y digno de las EIP.

(2) Essity, Sydney, Australie

Context: Fracture management accounts for one percent of patient presentations to family medicine. Fractures that are uncomplicated, and low risk rarely require orthopaedic intervention. These fractures can be treated exclusively in family medicine. Barriers include inadequate remuneration and limited education in fracture management. This workshop will be presented under the banner of the WONCA Emergency Medicine (EM) Special Interest Group (SIG).

Objectives: To introduce family doctors to management of basic fractures.

Teaching method and workshop: Two types of teaching methods will be used. First, direct instruction. Attendees will be introduced to the concept of basic fracture management based on a recent publication by the presenting author entitled Basic fracture management in general practice.

Expected outcomes: Doctors will be able to see how easy it is to apply Plaster-of-Paris and Dynacast splints in family medicine. They will then be able to reference literature and videos for applying splints for fractures that they can manage in their family medicine clinic

Conclusion: Teaching family doctors to manage basic fractures in the community is a win-win-win situation. Patients benefit, as they avoid travel and long waits in hospital emergency departments. The healthcare system benefits because family medicine options for fracture management provide opportunities for hospital avoidance and reduce costs.

ID 1779- Myths and Realities of Antihypertensive Combination Therapy in Greece and Worldwide

Kye-Yeung PARK

Hanyang University Medical Center, Seoul, Corée (République de)

Context: High-density lipoprotein cholesterol (HDL-C) has long been considered cardioprotective, yet recent studies suggest a U-shaped association with mortality, indicating possible harm at extremely high levels. Evidence from the XXX population remains limited, particularly regarding sex-specific patterns and cause-specific mortality.

Objectives: The study aimed to (1) examine the association between extremely high HDL-C and all-cause and cause-specific mortality, (2) identify sex-specific nadir points in the HDL-C–mortality curve, and (3) evaluate whether the association between HDL-C and mortality is modified by LDL-C levels, and whether extremely high HDL-C remains protective across LDL-C categories.

Methods: A nationwide longitudinal cohort from XXX was analyzed, in which participants

who underwent baseline health examinations were followed for up to 12.3 years. HDL-C was assessed using categorical groups (10 mg/dL increments) and as a continuous measure using restricted cubic spline models. Outcomes included all-cause mortality and cause-specific mortality (cardiovascular disease [CVD], cancer). Analyses were stratified by sex and adjusted for demographic variables, lifestyle factors, comorbidities, and lipid profiles.

Results: During follow-up, 3.8% of participants died. HDL-C exhibited a U-shaped association with all-cause mortality, with nadirs at 40–50 mg/dL in men and 60–70 mg/dL in women. Low HDL-C (<40 mg/dL) was associated with substantially higher CVD mortality across LDL-C categories, with risk rising steeply at the lower range. Associations at extremely high HDL-C levels were less robust. For cancer mortality, low HDL-C showed a modest increase in risk, whereas findings at very high HDL-C levels were weak and not statistically consistent. Extremely high HDL-C did not demonstrate a protective association in any LDL-C category and showed only modest risk elevation at very high levels.

Discussion: The findings support a non-linear, sex-specific relationship between HDL-C and all-cause mortality. The pattern observed across LDL-C categories suggests that extremely high HDL-C may not provide additional protective effects.

Conclusion: HDL-C demonstrated a sex-specific U-shaped association with mortality, with men exhibiting a lower nadir than women. Extremely high HDL-C levels may serve as a potential risk indicator rather than a protective marker. These findings highlight the need for careful clinical assessment of HDL-C in the context of overall lipid profiles.

ID 563- Narrative medicine and professional development: physicians' views ten years post-training

Fernanda PIRES DILLY [(1)], Felipe ALVES DOS SANTOS [(2)], Marcela SEIBERT [(2)]

(1) Fiocruz, Barra Do Piraí, Brésil
(2) Icepi, Vitória, Brésil

Context: Clinical skills and competencies are fundamental for strengthening Primary Health Care (PHC), but they require structured training. This teaching experience report addresses the use of clinical case discussions through the SOAP (Subjective-Objective-Assessment-Plan) and SNAPPS (Summarize-Narrow-Analyze-Probe-Plan-Select) tools, in addition to structured feedback, within a primary care specialization program in Brazil.

Methods: Forty clinical case presentations brought by the students during class were analyze. The students used the SOAP and SNAPPS methodologies to organize their clinical reasoning and presentation. After each presentation, structured feedback was provided using the Preceptor-Minute technique, which follows five established steps to ensure good clinical discussions and improve learning.

Originality: It is a rich experience in clinical case discussion with a pre-established structure for strengthening clinical reasoning, presentation, and feedback in a large-scale public health training program for providing physicians for Primary Health Care in Brazil.

Lessons learned and future implications: It was possible to observe that the students initially had difficulty understanding and applying the structured method of presentation. After the first few presentations, the students felt more confident and showed an improvement in the organization of their thought process and reasoning, as well as in their receptivity to feedback. The focus should be on structured methodologies with feedback to ensure high-quality training.

Discussion: The results suggest that although some of the students were able to report the cases, they lacked an adequate technique for discussion, presentation, and receiving feedback. This experience was important for the students to identify their knowledge deficits, improve their practice, and offer better health care for their patients.

Conclusion: The use of a specific methodology, which includes tools that adequately structure clinical reasoning, case presentation, and discussion, made it possible to clearly perceive

which clinical skills each student needed to improve, demonstrating that the learning process must be combined with effective teaching and learning techniques.

Context: Home-based interventions are patient-centered models of care for adults with cardiometabolic diseases.

Objectives: To map randomized clinical trials (RCTs) of home-based interventions in adults with cardiometabolic risk factors or cardiometabolic diseases.

Methods: A systematic search of RCTs was conducted in the electronic databases of Pubmed and CENTRAL (July - September 2024). RCTs of interventions that were delivered remotely or through home visits by health professionals in community dwelling adults with cardiometabolic risk factors or cardiometabolic diseases evaluating patient or health services use outcomes were included. Non-English studies, studies that addressed transitional care, and studies conducted in institutionalized populations were excluded from the review. To illustrate potential research gaps, tables were created, grouping the studies by intervention category, by outcome category, according to clinical condition, and according to reference to frailty, disability and social vulnerability.

Results: 102 RCTs (118 interventions) were found. Eighty-five (83.4%) were related to the chronic care of patients with a disease, mainly hypertension and type 2 diabetes mellitus. Four (3.9%) focused on frail older adults, 9 on patients with disabilities (10.8%) and 36 (35.3%) on patients with social vulnerability. Of the 118 interventions, 87 (73.7%) had multiple components. Eighty-six (72.9%) included behavioral intervention, 66 (55.9%) device use, 23 (19.5%) intervention on structure, 10 (8.5%) service process change, 10 (8.5%) physical exercise, 7 (5.9%) medication use, and 6 (5.1%) diet. In 79 (67%) , guidance and monitoring of the home intervention was provided remotely exclusively [50 (42.4%)] or in combination with in-person meetings in a health facility or at home [68 (57.6%)]. In addition to effectiveness [99 (99%)], 68 RCTs also assessed patient-centered outcomes (66.7%), 46 safety (45.1%) and 29 (28.4%) health service utilization outcomes.

Discussion: Evidence from RCTs suggests that home-based interventions have potential improvements for patients with cardiometabolic disease and those at risk.

Conclusion: RCTs of home-based interventions in patients with cardiometabolic diseases or cardiometabolic risk factors focus on the care of a limited number of individual chronic diseases and rarely include patients with frailty, disability or social determinants of health.

ID 1600- National epidemiological overview of LGBTQIAPN+ health inequalities in Brazil: insights from public datasets to guide primary care policies

Yasmina HANDAJI

Ufr Des Sciences De Santé De Dijon, Auxerre, France

Context: Menopause is a physiological transition that may lead to distressing climacteric symptoms, including vasomotor hot flashes, vaginal dryness, and urinary incontinence. Despite several therapeutic options, menopausal hormone therapy (MHT) remains controversial after the 2002 Women's Health Initiative study, and heterogeneous guidelines complicate prescribing decisions for general practitioners (GPs).

Objectives: This study aimed to characterize GPs' therapeutic approaches to climacteric symptoms.

Methods: A cross-sectional observational study was conducted using a self-administered questionnaire distributed between April and July 2024 to licensed GPs in XXX, excluding those working exclusively in hospitals. Data analysis included Chi-square tests and Mann–Whitney tests for age and years of practice.

Results: Among 379 respondents, 282 questionnaires were eligible; 70 were excluded due to missing data and 27 due to contradictory responses. MHT had been initiated by 69% of GPs and renewed by 90%, mainly for disabling vasomotor symptoms (74%) and severe vaginal dryness (54%). First-line management of vasomotor symptoms included phytotherapy or homeopathy (70%) and lifestyle modifications (50%). Severe vaginal dryness was treated primarily with non-hormonal (62%) and local hormonal therapies (53%), while urinary incontinence was managed mainly with pelvic floor rehabilitation (82%) and specialist referral (32%). Specialist referral was the most common second-line option across all symptom categories. Age, years of practice, university supervising role, and gynecology training were significantly associated with MHT initiation, while only sex and supervising status were linked to renewal. Main barriers to prescribing MHT were

insufficient training, perceived unfavorable risk–benefit balance, and the belief that management should be under gynecologists' care.

Discussion: Potential selection and self-reporting biases and limited sample representativeness are acknowledged. Strengths included a large sample, carefully designed questionnaire, and mixed online and in-person distribution, supporting the reliability of the findings. Other studies also show interest of some GPs in homeo-phytotherapy, despite its lack of superiority over placebo.

Conclusion: GPs in XXX reported prescribing MHT mainly for distressing climacteric symptoms, particularly for treatment renewal. Non-hormonal approaches and specialist referral remained widely favored, resulting in practices not always aligned with current guidelines. Further research is needed to understand determinants of GPs' reluctance to prescribe MHT. Keywords: Menopause; Climacteric; Estrogen Replacement Therapy; General Practitioners; Primary Health Care

ID 518- Natural pregnancy following regular running in a subfertile couple: a practice-based reflection by a family physician

Begoña JOVELL, Laura JOVELL

Cap Santa Clara, Girona, Espagne

Context: Forestier syndrome, also known as Diffuse Idiopathic Skeletal Hyperostosis (DISH), is a rheumatological disorder characterized by ectopic calcification and excessive bone formation in the ligaments and tendons, particularly along the spine. Due to its subtle clinical manifestations and overlap with degenerative spinal diseases, the condition is often underdiagnosed in primary care. Early recognition is crucial due to its association with increased risk of metabolic syndrome, vertebral fractures, and, rarely, dysphagia or myelopathy.

Methods: A 61-year-old male presented with a 3-week history of progressive dorsal back pain, without accompanying symptoms of dysphagia, neurological deficits or radiation of pain. He denied any recent trauma. He reported a history of self-resolving complaints of dysphagia ten years prior. No other significant past medical history was identified. Physical examination revealed tenderness in the bilateral dorsal paravertebral muscles, but no pain was elicited upon palpation of the spinous processes of the vertebral bodies. There were no focal neurological deficits, and muscle strength and sensation in the lower extremities were intact bilaterally. Plain x-rays of the thoracic spine revealed flowing ossification along the anterior longitudinal ligament spanning multiple contiguous vertebral bodies, with no evidence of fracture or acute osseous injury. These radiographic findings are consistent with the diagnostic criteria for Forestier syndrome.

Originality: This case report highlights the diagnosis of Forestier syndrome, emphasizing radiographic diagnostic criteria, clinical presentation, and the importance of early recognition to prevent potential complications.

Lessons learned and future implications: Forestier syndrome is an uncommon disorder in primary care and can be overlooked if its presentation and basic diagnostic criteria are unknown. Radiographic imaging is essential for diagnosis, as clinical symptoms can be mild or absent.

Discussion: Undiagnosed Forestier syndrome in primary care can result in progressive spinal stiffness and pain, often misattributed to more common spinal conditions, leading to suboptimal management. Hyperostotic segments fracture easily, and missed injuries can cause significant neurological damage. It may also cause dysphagia, airway obstruction, or myelopathy, occasionally becoming life-threatening.

Conclusion: This case underscores the importance of primary care physicians recognizing the radiographic features of Forestier syndrome and considering it in the differential diagnosis when evaluating older adults presenting with spinal pain and stiffness.

ID 689- Navigating a New System: Helping New Resident Doctors Adapt, Learn, and Lead

Venkatram NAVANEETHA KRISHNAN, Aneeq Ahmed SHAIKH, Mayukh BHATTACHARYYA

Sangam Surgery, London, Royaume-Uni

Context: Primary care plays a vital role in continuity, patient-centred follow-up, and long-term disease monitoring. NICE provides guidelines on a comprehensive annual review, including an assessment of functional ability, comorbidity risk and complications. General practitioners (GPs) are well-equipped to deliver personalised care by addressing the patient's unique needs, concerns, and preferences. By engaging in patient education and shared decision-making, patients are empowered to take an active role in managing their own health. Additionally, the GP's holistic approach facilitates access to social care, caregivers, and council services – addressing wider emotional and social determinants of health.

Methods: This audit reviews the existing clinical practice for RA annual reviews compared to the NICE guidelines. It particularly focuses on identifying opportunities to enhance medication adherence, comorbidity detection, and holistic follow-up.

Originality: Forty-seven patients were randomly reviewed for documentation of annual RA monitoring, comorbidity screening, and complications. Functional ability was assessed using a Health Assessment Questionnaire (HAQ), which was completed by 24 patients over the telephone.

Lessons learned and future implications: Only 5 patients had a coded annual RA review. CVD risk screening was consistent; however, osteoporosis and depression screening were under-recorded. Only 15% of patients underwent all three risk assessments. The mean HAQ score was 2, indicating moderate functional disability. Approximately 10% of patients had no contact with the practice despite repeated outreach.

Discussion: This audit highlights multiple challenges specific to primary care. A high workload, competing long-term conditions, and tight time constraints limit the depth of review, reducing opportunities for thorough, patient-centred follow-up. Non-attendance further restricts the clinician's ability to identify deterioration early.Addressing health literacy and patient education is crucial in combating this issue. The HAQ revealed functional decline that was not clear in routine consultations. This highlights the value of structured assessments in unmasking unmet needs. These, however, are time-consuming, exaggerating the time bottleneck that GPs already face.

Conclusion: Delivering holistic care through better patient education, improved comorbidity screening and technology implementation through pre-appointment digital HAQs, will vastly improve RA follow-up in primary care.

ID 1488- Navigating clinical uncertainty in primary care: communication, safety-netting and reflective practice

Laura JOVELL, Daniel ALCANTARILLA

Cap Santa Clara, Girona, Espagne

Context: Occult fractures are real fractures not initially visible on standard X-rays, but are later identified through advanced imaging such as CT scans or MRIs. They are often clinically suspected based on disproportionate pain, localized tenderness, swelling, or functional limitations. Although less common than visible fractures, they hold significant clinical importance.

Methods: A 58-year-old man presented with persistent, localized pain in his left knee following a minor injury sustained after falling from his parked motorcycle. Medical history: No known allergies. Former smoker. Non-toxic consumption. COPD. Hypercholesterolemia. Sleep apnea. Chronic renal failure. Physical examination: The left knee displayed normal symmetry, with no signs of ecchymosis, edema, or structural deformity. Minor superficial abrasion located at the inferior pole of the patella. Patellar ballottement was positive, consistent with a mild joint effusion. There was no tenderness on palpation along the medial or lateral femoropatellar joint lines nor patellar mobilization. Knee flexion was restricted secondary to pain. Ligamentous stability was preserved, as indicated by negative anterior and posterior drawer tests. Meniscal provocative tests were negative, suggesting no clinical evidence of meniscal injury. Follow-up: Persistent pain one month after the injury, which showed no significant improvement despite rest and non-steroidal anti-inflammatory drugs (NSAIDs). Initial X-rays revealed no evidence of acute bone injury. Physical examination: minimal synovial effusion. Given the ongoing pain and functional limitations, the patient was referred for advanced imaging, requesting an MRI. Evolution: Left knee MRI results: Non-displaced linear fracture of the posterior aspect of the external tibial plateau, accompanied by bone edema.

Originality: This case emphasizes the diagnostic value of integrating the patient's symptoms and clinical judgment when assessing trauma in primary care.

Lessons learned and future implications: Even in the absence of radiological signs of acute injury, persistent symptoms and functional impairment warrant further investigation, particularly with high clinical suspicion of an occult fracture.

Discussion: Highlighting the necessity of a comprehensive, patient-centered approach in primary care, humanism and clinical acumen play vital roles in recognizing red flags that could indicate occult fractures.

Conclusion: This case is a reminder of core principles in family medicine: continuity of care, knowing the patient, patient-centered communication, and diagnostic skills through active listening and thorough evaluation.

Corresponding author: Laura Jovell, laurajovellmd@gmail.com

ID 1128- Navigating Systemic Challenges to Achieve Optimal Primary Health Care

Fernando FARIAS, Jorge CATTANI

Souza Marques Medical School, Rio De Janeiro, Brésil

Context: Cardiovascular risk (CR) is a major epidemiological marker associated with clinical conditions of high epidemiological impact which require long-term vigilance and adhesion to treatment. In XXX, community health workers (CHW) are a pillar of primary care, and

are professionals with a high demand for long daily walks in order to perform their basic tasks inside the community. Medical literature has emphasized daily step count (DSC) as a factor inversely associated with CR in other populations. Association between CR risk and DSC has not been studied for XXX CHW.

Objectives: The aim of this study was to evaluate a putative association between CR and DSC for CHW in a family health center in XXX.

Methods: This study was part of an undergraduate extension program. CHW were trained in the usage of the free cell phone applications that quantified CR and DSC, and then scheduled to return 30 days later. Upon return, CHW filled out a form containing every parameter needed to feed the CR calculator, including some measured on the spot. Form also collected DSC for every preceding 14 days, and the average DSC was calculated. Association between CR and DSC were analyzed by linear regression and Mann-Whitney U-test. This protocol was approved by the institutional ethics committee.

Results: Participant CHW were n=36; 77,70 % were female; 58,3 % were older than 40 years; 80,5 % were overweighted or obese; 33,3 % had high blood pressure; 27,7 % had moderate to high CR; 63,8 % had DSC higher than 5.000. Statistical analysis found no significant association between CR and DSC, even when CWH were further stratified into subsets.

Discussion: Contrary to expected from current medical literature, no association was found between CR and DSC for CHW. One hypothesis is this group is too small and heterogeneous, not reflecting general population. Another possibility is daily walking is not protective enough from hazards like high blood pressure or obesity, which would demand specific attention.

Conclusion: In conclusion, CHW in a family health center in XXX do not seem to get benefit in a simple way from high DSC, emphasizing the importance of comprehensive preventive health care.

Context: Liver enzyme abnormalities are frequently detected in routine primary care testing. In patients with obesity and dyslipidemia, these abnormalities are often attributed to metabolic causes. However, when autoantibodies are present, the differential diagnosis must be broadened to include autoimmune liver disease and drug-induced liver injury. Statins, although safe, can rarely trigger immune-mediated hepatitis.

Methods: A 52-year-old woman with obesity, mixed dyslipidemia, elevated Lp(a), and hepatic steatosis was receiving atorvastatin. Routine blood tests revealed persistent elevation of AST, ALT, GGT, and IgG. Autoimmune screening showed ANA 1/1280, AMA positive, and anti–smooth muscle antibodies 1/640. An abdominal ultrasound was normal. Elastography measured 9.6 kPa. Given the mixed analytical pattern, a liver biopsy was performed. Atorvastatin was discontinued and serial blood tests were monitored.

Originality: This case illustrates how statin-induced hepatotoxicity may present with positive autoantibodies, closely resembling Primary Biliary Cholangitis (PBC) or autoimmune hepatitis. Such autoimmune-like drug reactions are rare and poorly recognized in primary care

Lessons learned and future implications: Primary care clinicians should consider statins as a potential cause of immune-mediated liver injury—even when autoantibodies suggest autoimmune disease. Liver biopsy and temporal correlation with medication exposure are key to establishing the correct diagnosis. Future protocols could incorporate earlier evaluation of drug-related causes in atypical autoimmune serologies.

Discussion: The coexistence of AMA positivity, elevated IgG, and steatosis initially suggested PBC. However, the biochemical pattern was not predominantly cholestatic, symptoms were absent, and imaging was normal. Liver biopsy revealed findings consistent with drug-induced hepatitis rather than autoimmune disease. Importantly, liver enzymes and IgG improved markedly after stopping atorvastatin, confirming causality. Recognizing this pattern prevents misdiagnosis and unnecessary immunosuppressive treatment.

Conclusion: In patients with metabolic risk factors on statin therapy, elevated liver enzymes with autoantibodies require careful interpretation. This case highlights that statin-induced hepatitis can mimic PBC or autoimmune hepatitis. Biopsy and drug withdrawal were decisive for diagnosis and full recovery. Primary Care plays a crucial role in identifying, evaluating, and correctly attributing these abnormalities.

Estefania Dolores GONZALEZ MARTIN, Eva Maria SANTIAGO SANCHEZ, Maria Lourdes MATEOS SANCHEZ, Evelin TRASTOY JIMENEZ, Ana Maria CHUCHON ALVA, Viorel CIOCEA FICIU, Anda Magdalena CIOCEA

Primary Care, Avila, Avila, Espagne

Context: Papillary renal cell carcinoma (PRCC) is a malignant tumour arising from the renal tubular epithelium, representing 10–15% of renal cell carcinomas, with a male predominance. It may present with paraneoplastic symptoms, including constitutional syndrome in one-third of patients, typically fever, weight loss, and nausea. These manifestations are mediated by cytokines such as IL-1, interferons, and prostaglandins, which may also contribute to diarrhoea, flushing, and fever.

Methods: A 47-year-old man with type 1 diabetes mellitus presented to Primary Care with one week of non-bloody diarrhoea. Stool cultures excluded infection. He subsequently developed constitutional symptoms, including unintentional weight loss of 10 kg, disproportionate to stool frequency. Laboratory tests revealed hypoproteinemia, and he developed bilateral lower limb oedema, asthenia, and bendopnea. He was admitted to Gastroenterology. CT imaging identified a mass in the upper pole of the left kidney, and a renal tumorectomy was performed. Histopathology confirmed papillary renal cell carcinoma (pT1a Nx Mx). Strengths included close follow-up in Primary Care, enabling early recognition of red-flag signs and timely referral. Limitations involved prolonged waiting times for other specialist consultations and diagnostic procedures, which delayed definitive diagnosis.

Originality: Chronic diarrhoea in a patient with type 1 diabetes typically suggests autoimmune gastrointestinal disease. In this case, however, diarrhoea was a paraneoplastic manifestation of PRCC. Literature describes such syndromes but they remain rare and difficult to recognize in routine practice.

Lessons learned and future implications: This case underscores the importance of considering paraneoplastic syndromes in atypical presentations, maintaining vigilance for red-flag symptoms, and strengthening coordination between Primary Care and hospital services to avoid diagnostic delays.

Discussion: PRCC accounts for 15% of renal cell carcinomas and occurs more frequently in men. Epidemiologic studies suggest increased cancer risk in patients with diabetes, including kidney malignancies, though evidence specific to type 1 diabetes and PRCC remains limited.

Conclusion: This case highlights the critical role of family physicians in detecting atypical presentations, maintaining broad differentials, and ensuring effective communication across specialties to improve patient outcomes.

ID 1026- Necrotic Tonsillitis as a Warning Sign: A Primary Care Presentation of Methotrexate-Associated EBV-Positive Lymphoproliferative Disorder

Iria CAUSÍN FÓRNEAS, Yaiza GIANZO VILLAVERDE

Residente Medicina at Centro de Salud de La Calzada, Gijon, Espagne

Context: Subacute thyroiditis is an uncommon diagnosis in primary care and may initially resemble upper respiratory infections. Its nonspecific symptoms—such as odynophagia, anterior neck pain, and constitutional manifestations—often lead to repeated consultations and ineffective treatments. This case illustrates the importance of clinical suspicion and the role of point-of-care ultrasound in evaluating persistent throat-related symptoms that do not align with typical ENT findings.

Methods: A 51-year-old woman presented with a three-week history of persistent odynophagia, neck pressure, low-grade fever, malaise, and unintentional weight loss, despite multiple evaluations and antibiotic courses. A detailed history and focused cervical examination revealed tender bilateral lymphadenopathy and a painful thyroid mass mobile with swallowing. Point-of-care ultrasound was performed to assess for structural abnormalities, and laboratory tests were ordered, including thyroid hormones, CRP, ESR, and thyroid autoantibodies. Corticosteroid therapy was initiated with a gradual taper planned over six to eight weeks. Follow-up laboratory studies and a formal cervical ultrasound were scheduled to monitor disease progression and treatment response.

Originality: This case presents an atypical clinical picture in which odynophagia predominated despite a normal oropharyngeal examination. It demonstrates how subacute thyroiditis can be overlooked when symptoms overlap with more common infectious conditions. The case also highlights the expanding diagnostic capability of primary care through bedside ultrasound, a tool increasingly accessible to frontline clinicians.

Lessons learned and future implications: This case underscores the need to consider thyroiditis in patients with persistent throat pain and anterior neck tenderness that do not respond to standard therapies. Point-of-care ultrasound is a valuable tool that enhances diagnostic accuracy and may reduce unnecessary treatments. Future applications include broader implementation of ultrasound training in primary care and the development of standardized diagnostic pathways for evaluating prolonged cervical discomfort.

Discussion: Laboratory findings confirmed subacute thyroiditis, with suppressed TSH, elevated T4, and markedly increased inflammatory markers. Rapid clinical improvement after corticosteroid initiation aligned with expected disease behavior. The case underscores how early recognition prevents delays and avoids unnecessary medications, while bedside ultrasound supports real-time clinical decision-making.

Conclusion: Subacute thyroiditis, though uncommon, should be included in the differential diagnosis of persistent odynophagia. Strengthening ultrasound competencies in primary care may improve earlier detection and outcomes.

Context: Effective communication is crucial in Primary Health Care (PHC) but often lacks structured training in in-service programs. This report describes the implementation of video analysis using the Calgary-Cambridge Observation Guide (CCOG) within a specialization course for a large-scale national primary care provision program in Brazil.

Methods: We analyzed 20 video-recorded consultations from 10 family medicine trainees. The 28-item version of the CCOG was used as a

formative assessment tool. Following established feedback protocols, sessions prioritized the learner's agenda and anchored comments to specific guide items , avoiding clinical judgment to focus strictly on communication skills. The process aimed to identify specific behavioral gaps in a safe learning environment

Originality: This experience is innovative in its systematic application of the CCOG within a massive public health training program. It differentiates itself by using quantitative video data to deconstruct the common assumption among professionals that "politeness" is equivalent to "technical communication competence."

Lessons learned and future implications: Data revealed a distinct pattern: while 100% of participants excelled in politeness and initial rapport (Items 1-3), significant technical gaps were identified. Notably, 85% failed to use internal summaries (Item 17), 75% did not negotiate the agenda (Item 5), and 55% used unclear language (Item 10). Furthermore, 40% missed exploring the patient's perspective (Items 13-14). Future training must shift focus from general humanization to specific structuring techniques

Discussion: The results suggest that physicians in this context possess strong relational skills but lack structural techniques. The high failure rate in "agenda setting" and "summarizing" indicates reactive rather than proactive consultation management. Video evidence was pivotal in highlighting these deficits, including non-verbal interferences like computer use, observed in 25% of cases.

Conclusion: Using the CCOG on video recordings transformed subjective perceptions into actionable educational data. It proved effective in diagnosing specific skill gaps, demonstrating that empathy must be paired with structured communication techniques to improve quality of care.

(2) Primary Care, Zaragoza, Zaragoza, Espagne

Context: Ustekinumab is a monoclonal antibody targeting the p40 subunit of interleukins IL-12 and IL-23. It has demonstrated efficacy in mucosal healing and is indicated for moderate to severe Crohn's disease in adults with poor response to anti-TNF therapy or contraindications. Common adverse effects include upper respiratory infections, nausea, and dizziness. Although generally well tolerated, rare reactions such as facial paralysis have been reported.

Methods: A 63-year-old male with supraglottic squamous cell carcinoma (cT3 cN2 M0), treated with radical chemoradiotherapy and cisplatin, complicated by severe hematologic toxicity, also had Crohn's disease managed with ustekinumab. Two days after the first dose, he presented to Primary Care with left facial paraesthesia and deviation of the mouth. Neurological examination revealed left peripheral facial palsy without otalgia, otorrhea, or dysphagia. Differential diagnoses included idiopathic Bell's palsy, stroke, post-viral infection, Lyme disease, oncologic toxicity, Ramsay Hunt syndrome, and neoplastic involvement of the facial nerve. Strengths of the case included a thorough neurological assessment in Primary Care, guiding appropriate referral. Limitations were the inability to confirm etiology without imaging. At hospital level, ENT pathology was excluded, and treatment with corticosteroids and ocular protection was initiated. The patient was diagnosed with House-Brackmann grade IV–V peripheral facial palsy, considered a possible adverse reaction to ustekinumab.

Originality: The originality lies in the onset of facial paralysis shortly after ustekinumab initiation, a rare adverse effect documented in limited reports. The coexistence of immunomodulatory therapy, oncologic immunosuppression, and acute neurological symptoms required an expanded differential diagnosis.

Lessons learned and future implications: This case highlights the importance of early neurological evaluation and vigilance for rare adverse effects of biologics, especially in immunosuppressed patients. It underscores the need for continuous updating on emerging drug reactions and reinforces the value of coordination between Primary Care and hospital services.

Discussion: The case illustrates the challenges of managing neurological symptoms in immunosuppressed patients with multiple comorbidities, particularly in resource-limited settings.

Conclusion: This case emphasizes the crucial role of the family physician in early detection of neurological signs and comprehensive assessment of complex patients. The possibility of facial paralysis associated with ustekinumab underscores the need for up-to-date knowledge regarding biological therapies and vigilant monitoring in Primary Care.

Department Of Endocrinology, Internal Medicine And Infectious Diseases, University Hospital Of Mahdia-Mahdia (tunisia), Mahdia, Tunisie

Context: Acute focal bacterial nephritis (AFBN) is a rare pre-suppurative complication of acute pyelonephritis that can be severe, particularly in elderly patients.

Objectives: Describe the epidemio-clinical, microbiological, radiological, therapeutic characteristics and outcomes of AFBN.

Methods: We conducted a cross-sectional study including elderly patients who were hospitalized in our department for AFBN between 2014 and 2024.

Results: Twelve patients were included, eight women (75%) and four men (25%), with a mean age of 67 years (range 65–80 years). The most common comorbidity was diabetes mellitus (58.3%). Clinical manifestations were dominated by fever (83.3%), flank pain (66.7%), and dysuria (50%). Leukocytosis and a C-reactive protein level > 200 mg/L were noted in 83.3% and 66.7% of cases respectively. Escherichia coli was the most frequently isolated pathogen (58.3%). Radiological assessment was primarily based on CT urography (66.7%) and renal ultrasonography (33.3%). Focal bacterial nephritis was multiple in three cases (25%). All patients were treated with dual antibiotic therapy: a combination of a third-generation cephalosporin and an aminoglycoside in nine cases (75%) and a combination of a third-generation cephalosporin and a fluoroquinolone in three cases (25%). The clinical and radiological course was favorable in all patients (100%) after a mean duration of antibiotic therapy of 19.1 days (14–21 days).

Discussion: AFBN in the elderly is likely underdiagnosed, as its clinical presentation closely mimics that of uncomplicated acute pyelonephritis based on clinical features alone. AFBN in the elderly occurs more frequently in women with diabetes mellitus being the most common associated comorbidity. Escherichia coli remains the predominant pathogen. Diagnosis relies on radiologic imaging. The uniformly favorable outcomes observed with prompt dual antibiotic therapy underscore the importance of early recognition.

Conclusion: AFBN requires early diagnosis and prompt appropriate management, with heightened vigilance in elderly patients to preserve renal function.

ID 2294- Neuromeiningeal manifestations in patients living with HIV

Anthony GADOULEAU, Fanny SERMAN

Department Of General Medicine, University Of Lille, Lille, France

Context: Breastfeeding is a significant public health issue, offering well-established benefits for both mother and child. The experience of breastfeeding is shaped not only by biological and social factors, but also by the quality of medical and emotional support received after childbirth. The general practitioner (GP) plays a pivotal role in continuity of care, yet their involvement in providing breastfeeding support is not well understood.

Objectives: To explore the meaning of the GP–parent relationship in supporting breastfeeding through an approach that focuses on lived experiences.

Methods: A qualitative interpretative phenomenological analysis (IPA) was conducted with six mothers living in XXX who had exclusively breastfed their full-term children under the care of a GP. Participants were recruited via posters in medical practices, social networks, and personal contacts. Data were collected through non-directive interviews, which were recorded and fully transcribed. Analysis was performed according to IPA stages in symmetrical triangulation between two researchers until data saturation was achieved.

Results: Breastfeeding was found to be a complex experience, incorporating physical, emotional and social elements. The GP–mother relationship fluctuated between recognition and misunderstanding, depending on the physician's capacity to listen, validate emotions, and customise guidance. Mothers valued relational qualities such as empathy, trust, and recognition of their expertise as mothers, perceiving these qualities as therapeutic in themselves. Conversely, a lack of acknowledgement or a prescriptive stance from the GP often reinforced maternal guilt and isolation.

Discussion: This study provides an original exploration of the breastfeeding experiences of mothers in relation to their GP. Its methodological strengths include in-depth, rich interviews; a reflexive stance; and rigorous triangulation. The study highlights relational factors that shape breastfeeding and supports the public health relevance of the topic. However, limitations relating to sampling, contextual specificity, timing, researcher influence and the lack of clinical observation mean that there are several avenues for future research.

Conclusion: This study highlights the importance of the relationship between GPs and mothers in determining whether they continue to breastfeed. The GP's role extends beyond providing medical advice to encompass offering emotional and symbolic support. Training programmes should therefore integrate experiential and phenomenological approaches to strengthen the relational foundations of primary care.

(1) Family Medicine Resident, Madrid, Espagne
(2) Family Medicine Attending, Madrid, Espagne

Context: Primary healthcare with referral to Dermatology.

Methods: Woman, 33 years old, with no previous medical history, goes to her Family Medicine physician with blister-like cutaneous lesions that emerge and resolve spontaneously and intermittently, predominantly involving her hands, arms, anterior chest and lower extremities for the last seven years. In the past year, she has exhibited the same type of lesions in a persistent pattern, primarily affecting arms and hands. Any other symptoms where denied. Initially a diagnosis of scabies was made, starting permethrin as treatment. Due to lack

of clinical improvement, the patient consult again at a Primary Care, so she was referred to Dermatology. At Dermatology in the physical exam it was described blistering and crusted skin lesions in the back of the hands and forearms. Urine and blood where analyzed, in urine elevated uroporphyrin was found and in blood elevated liver enzymes where reported, with those findings, porphyria cutanea tarda (PCT) was made and the patient started a follow-up.

Originality: This was a typical PCT case, but is interesting that initially an scabies diagnosis was made. Since the lesions of the patient had an intermittent pattern and she'd never consult for this before, it was difficult to make a proper diagnosis in the first consult, in her second visit to consult, a new physical exam was made and the patient was referred to Dermatology.

Lessons learned and future implications: In Primary Care, PCT should be suspected in adults presenting with fragile, photosensitive skin on sun exposed areas specially in hands with blisters, erosions, milia, and hypertrichosis.

Discussion: PCT is a common type of porphyria and results from decreased activity of uroporphyrinogen decarboxylase, leading to porphyrin accumulation in the skin and liver. It typically presents with photosensitive, fragile skin on sun-exposed areas, causing vesicles, bullae, erosions, and scarring after minimal trauma. Risk factors include alcohol use, hepatitis C, HIV, estrogen therapy, sun exposure, and iron overload. The Primary Care physician, should control those risk factors in patients with PCT.

Conclusion: Early recognition of PCT in Primary Care is essential to prevent ongoing skin damage. Prompt referral, targeted investigations, and trigger avoidance enable effective management and improve long-term outcomes.

(3) Medutools, Kraków, Pologne

Context: Community-acquired pneumonia (CAP), particularly caused by Streptococcus pneumoniae, is an important cause of morbidity and mortality. Early and accurate diagnosis is crucial for effective treatment, particularly for selecting the appropriate antibiotic therapy, to combat antimicrobial resistance (AMR). Rapid antigen tests can improve the accuracy of bacterial etiology diagnosis and facilitate targeted therapy. This study evaluates the feasibility of implementing a rapid antigen test for pneumococcal pneumonia in primary care settings across Poland.

Objectives: The aim of this study is to assess the preliminary outcomes of implementing a rapid antigen test for diagnosing pneumococcal pneumonia in primary care. We focus on the impact of training primary care teams on the number of patients tested, the confirmation rate of bacterial etiology, and the appropriateness of antibiotic therapy with respect to AMR.

Methods: Ten primary care teams from various regions in Poland were trained in using a rapid antigen test to diagnose pneumococcal pneumonia. Data were collected via online monitoring and a Computer-Assisted Web Interview (CAWI) survey of healthcare staff, which gathered information about the number of patients with suspected pneumonia who were tested, the number of confirmed positive and negative cases, and the subsequent antibiotic treatment prescribed. Data analysis will compare the diagnostic and antibiotic management outcomes before and after the introduction of the test.

Results: In the initial phase 75 patients with suspected pneumonia will be enrolled. Of these the authors suspect that 37% were confirmed

positive for pneumococcal antigen (according to Polish morbidity data). The proportion of patients receiving narrow-spectrum antibiotics increased in the tested group, compared to the non-tested group. Barriers to the use of the test will be identified via survey. Hypothetically there will include time limitations, logistical challenges, and cost-effectiveness concerns.

Discussion: Preliminary results suggest that implementing a rapid antigen test in primary care improves pathogen-directed therapy and may contribute to better antibiotic stewardship, potentially reducing AMR. However, overcoming operational barriers is key for broader adoption.

Conclusion: The rapid antigen test for pneumococcal pneumonia shows promise in improving diagnosis and antibiotic selection in primary care. Further analysis will provide insights into its full potential for enhancing patient outcomes and combating AMR.

Michael BLACKMORE

Rcgp, Stirling, Royaume-Uni

Context: I've been in Recovery from opioid & benzo addiction for 16years now. I am now heavily involved in RCGP Scotland & Chair for my faculty, as well as UK Rep. I have been telling my story to UK conferences - the last time was to RCGP UK National Conference, main stage, which received a standing ovation. The feedback is always excellent. I plan to highlight drug-addiction behaviours & how to signpost addicts towards Recovery. Many of the suggestions can be used in day-to-day practice & help doctors establish rapport with addicted patients.

Objectives: Play the "A to Z" game of drug misuse - actual names, street names or ways of taking - to highlight drug trends. Always a fun interactive experience. Then I tell my own addiction/recovery story, highlighting how to avoid pitfalls in prescribing to addicts. Finish with Q&A session.

Teaching method and workshop: Interactive game, then presentation, then Q&A.

Expected outcomes: Reduce stigma & prejudices in dealing with addicts. Increased knowledge of why addicts behave in certain ways, & how to help them by using boundaries. Signposting Recovery pathways, & how to stay in Recovery.

Conclusion: This session always has the highest feedback for evry conference I've ever done it at, including RCGP UK conference, Drug & Alcohol conference, Secure environment conference & Medical Indemnity conference. I'm happy to send you my 16 minute TED-type talk if requested. Hugs not drugs

ID 1571- Not just symptoms: the hidden psychosocial cost of LUTS awareness

Michael BLACKMORE

Rcgp, Stirling, Royaume-Uni

Context: Scotland has among the highest drug misuse death rates in Europe, and the crisis is deeply stratified by socioeconomic deprivation. Understanding how drug misuse deaths vary by deprivation, geography, age, and drug type is critical for targeted interventions in general practice to reduce mortality and address health inequalities. Scotland is currently trying to address many of these issues, including naloxone provision, increasing rehab beds & the opening of the UK's first drug-consumption room. Of particular note, I am a GP (& RCGP Chair of West Scotland faculty, including Glasgow!) in recovery for 16 years from opioid/benzodiazepine addiction. During this time I have sat in hundreds of Narcotics Anonymous meetings & heard about all the mistakes that GPs make in dealing with addicts. Using this "insider knowledge" in my practice I have implemented policies that drastically reduce these opportunistic "polypharmacy" requests.

Objectives: To examine recent trends and inequalities in drug misiuse deaths in Scotland, highlight which populations and areas are most affected, and outline implications for general practice in prevention, early detection, and engagement.

Methods: Analysis of published statistics from National Records of Scotland (2023-2024) and related Police Scotland reports. Key metrics include total deaths, age-standardised mortality rates, deprivation quintiles, geographical distribution, substance implicated, and age/sex breakdown. Also, personal communication with rehab centres & consumption room lead (67 drug-related overdose interventions in < 12 months so far).

Results: In 2024, there were 1,017 drug misuse deaths in Scotland, a 13% decrease (155 fewer deaths) compared with 2023. People in the most deprived areas are 12x as likely to die from drug misuse compared to those in the least deprived areas. Substances implicated: opiates/opioids in ~80% of deaths: benzodiazepines ~56%; cocaine ~47% (increasing trend). Average age of death has increased from 32 years in 2000 to approx. 45 in 2024...

Discussion: Drug trends in Scotland past/present, & what we are doing to mitigate primary care's part in this by reducing prescriptions for opioid painkillers, benzodiazepines & gabapentinoids especially.

Conclusion: My "insider knowledge" from my own addiction/recovery has helped addicts, & those working in Primary Care to be more mindful when dealing with inappropriate requests for addictive medications.

ID 2198- Nursing digital influencers and health misinformation: a quanti-qualitative analysis of public profiles and audience connection justifications

Gaetan LEFEVRE

General Practionner, Lyon, France

Context: Down syndrome (DS) is the most common chromosomal abnormality. Various combinations of biological, ultrasound, and genetic markers are used to calculate the risk of fetal DS. The recent use of circulating free fetal DNA (cfDNA) has revolutionized screening policies by increasing the sensitivity and specificity of screening and limited the number of invasive tests.

Objectives: The objective is to describe the strategies adopted by the 27 EU countries in 2024 and to investigate possible harmonization following the discovery of cfDNA.

Methods: A descriptive review of the literature was conducted and supplemented by expert contributions from several European countries contacted specifically. The results were synthesized to answer twelve research criteria.

Results: Combined screening is used in all European countries, and used as a first line test in 21 countries. cfDNA testing is used as a first-line test in four countries, and recommended after risk calculation by combined screening in 13 countries. The prevalence of screening is over 80%. The strategy comes as an official national programme for 16 countries. Some form of antenatal screening is at least partially reimbursed in 25 countries. The methods used to inform couples about screening vary : dedicated consultation, information guide or routine test. In most countries, DNA analysis has been extended to include the detection of other genetic abnormalities. The termination of pregnancy after antenatal diagnosis of DS is authorised in 24 countries, mostly up to 22 or 24 weeks of pregnancy and performed in 70 to 100% of cases.

Discussion: Since the discovery of cfDNA, practices have evolved and two prenatal screening techniques remain : combined screening and cfDNA. The societal context varies : in several countries, screening is perceived as mandatory and the inclusion of people with disabilities is difficult. The widespread and extensive use of cfDNA raises ethical questions about access, legal framework for its use, preparatory information and ultimate purpose of this screening.

Conclusion: European harmonisation has been successful from a technical standpoint, but remains illusory on other aspects. General practitioners face numerous challenges : provide information helping couples to make enlightened decisions, discuss the use of cfDNA, and encourage inclusion while respecting couples' choices.

Context: Dengue is a leading cause of illness in Brazil and a common reason for Primary Health Care (PHC) visits. Early detection and proper risk assessment are critical to avoid complications. Training healthcare professionals requires both technical skills and empathetic communication. This report outlines a simulation-based educational approach to enhance these competencies for managing dengue without warning signs

Methods: A clinical simulation was held in a PHC Unit with a standardized patient showing typical non-severe dengue symptoms. Groups of 3 or 4 medical students completed triage, focused history, warning sign examination, patient education, and disposition planning. The session followed an advocacy inquiry debrief and national dengue guidelines.

Originality: The originality of this approach lies not only in its focus on dengue in Primary Health Care (PHC), but also in the combination of technical and interpersonal skills, preparing future professionals to offer more comprehensive and person-centered care, aligned with the health needs of the Brazilian population.

Lessons learned and future implications: Students showed improved confidence in distinguishing dengue without warning signs from potentially severe presentations, and provided more structured, empathetic communication during debriefing. The experience highlighted the need to reinforce recognition of clinical red flags and safety-net instructions. Plans include development of progressively complex scenarios, incorporation of practicing PHC teams and structured evaluation metrics to assess impact.

Discussion: The simulation proved effective for training in dengue case management, providing a valuable practical experience. The debriefing was crucial toconsolidate learning, allowing reflection on decisions made and review of dengue management protocols.

Conclusion: The activity demonstrates the positive impact of simulation in preparing future clinicians to deliver empathetic, safe and evidence-based care for high-prevalence conditions in community settings.

Context: Managing acute suicidal crises in individuals with bipolar disorder is a critical challenge in Primary Health Care (PHC). Effective care requires rapid risk identification, crisis de-escalation, communication skills, and coordinated safety planning. This practice-based reflection describes a simulation-based strategy designed to strengthen these competencies.

Methods: A simulation was conducted in a PHC unit using an actor portraying a 28-year-old man with bipolar disorder who exhibited psychomotor agitation, explicit suicidal intent, and a defined self-harm plan. Groups of six to ten students from multiple health disciplines conducted structured risk assessment,

environment control, safety interventions, communication with family members, and referral to mental health services. A structured advocacy inquiry debriefing followed the scenario, promoting reflection aligned with evidence-based protocols.

Originality: Few simulation exercises in Brazil address suicidal crisis management within PHC. This scenario integrates clinical, psychosocial, and ethical components while emphasizing multidisciplinary collaboration, core to Family Medicine.

Lessons learned and future implications: Participants demonstrated improved rapport-building, structured suicide assessment, and safety-planning skills. Training gaps included verbal de-escalation strategies and coordination with specialized teams. Plans include telemedicine elements, expanded crisis scenarios, and structured evaluation metrics.

Discussion: The simulation proved to behighly effective in training critical skills in the management of suicidal crises. The structureddebriefing was fundamental to consolidate the learning, allowing for reflection on the decisions madeand discussion of evidence-based protocols. The experience highlighted the importance of integrating mental health training into the education of primary care professionals

Conclusion: This simulation-based activity effectively prepares future clinicians to manage high-risk suicidal crises in PHC. It reinforces technical, communicational, and humanistic competencies essential for safe, empathetic mental health crisis care.

Context: In the 21st century, family medicine goes far beyond curing diseases. Faced with chronic conditions and not-communicable diseases, mental health challenges, and complex social issues, general practitioners increasingly act as guides and partners in their patients' health journeys. Our mission now includes promoting health, preventing illness, and empowering patients to care for themselves. The distinction between what is normal and what is pathological as well as the boundaries between our professional and the patient's private life makes the question of what is medical or not medical increasingly complex. Developing the ability to demedicalize whenever appropriate is emerging as a core competency for the future of general practice.

Objectives: Critical reflection on our own practices and what we include in our professional role or not. Discussion about how we deal with this evolving and complex professional role. Explore ways to manage this and how collaboration with the patients and other health professionals can help.

Teaching method and workshop: Clinical cases, small groups discussion, interactive wrap-up 1) Brief introduction of the context and the objectives (10 min) 2) Clinical cases guided discussion in small groups (20 min) 3) Interactive wrap-up (20 min) 4) Conclusion (10 min)

Expected outcomes: Critical reflection on one's own practice. Exploring how others do. Draft definition of our professional role.

Conclusion: The boundary between what is "normal" and what is "pathological" is neither fixed nor binary. It has shifted throughout history and continues to vary across socio-economic and cultural contexts.In the end, the role of the general practitioner is not defined by a disease but by the patient.

Context: May-Thurner syndrome (MTS) is an uncommon clinical entity that requires treatment to prevent complications.

Methods: A 45-year-old man presented to the emergency department with a one-week history of pain in the quadriceps muscle of the left lower limb, which had worsened over the previous 24 hours, accompanied by swelling and violaceous discoloration. He reported a 12-hour car- trip two weeks previously, at symptom onset. His medical history was notable for a sister who had three deep vein thromboses (DVT). Complementary tests showed: - Blood Test: D-dimer 4,900 ng/mL. - Thoracic CT-scan: Bilateral Pulmonary Embolism (PE). - Left leg ultrasound: Extensive thrombosis of the common, superficial, deep femoral veins, popliteal vein and tibioperoneal trunk. Subcutaneous oedema. The initial diagnosis was left femoropopliteal DVT with secondary bilateral PE. He began intravenous anticoagulation at the hospital. Oral anticoagulation and follow-up assessment post-discharge, including an abdominal ultrasound to rule out cancer. Two weeks later, he returned due to fever and increased pain: antibiotics initiated for possible cellulitis. After two months, patient received a final diagnosis of bilateral PE and MTS with associated DVT. Phlebography was performed, followed by venous revascularization and iliac stenting.

Originality: Among the differential diagnoses, scientific literature highlights: Phlegmasia cerulea dolens, Phlegmasia alba dolens, DVT, Aortoiliac Aneurysm, Cellulitis, Osteoarthritis, Gout, Heart failure, Abdominal cancer, Metastases and Pelvic diseases (Klein, 2024; Mousa, 2025). MTS is very uncommon, particularly in men. This case could easily have been missed due to patient being an atypical candidate.

Lessons learned and future implications: This case expands the range of conditions to rule out when DVT is suspected. Detailed anamnesis and additional diagnostics are advisable to determine aetiology and prevent complications.

Discussion: In MTS, the left common iliac vein is compressed between the spine and the right common iliac artery, causing venous obstruction and thrombus formation. Phlebography is the diagnostic gold standard while treatment involves thrombectomy and endovascular stenting.

Conclusion: When DVT is suspected, MTS may be present. This pathology should be considered due to its potentially complicated course and the need for specific treatment. In cases of DVT, underlying causes may range from simple triggers to anatomical abnormalities. Entity may appear in primary care.

ID 991- Occult Tibia Fracture: clinicoradiological dissociation

Gabrielle LISEMBARD [(1)], Fanny SERMAN [(2)], Kévin ROUARD [(1)]

(1) Ufr3s, Grand Fort Philippe, France
(2) Ufr3s, Lille, France

Context: Nutritional education is a key lever for health promotion. In France, the National Nutrition Health Program provides specific

recommendations to support general practitioners in promoting healthy dietary habits. However, patient adherence to these recommendations remains variable and depends on the quality of the informational tools available to them. The brochure “50 petites astuces pour manger mieux et bouger plus" (50 small tips to eat better and move more”) appears to meet the quality criteria defined by the French National Authority for Health (HAS).

Objectives: The primary objective of this study is to assess the impact of this brochure on participants’ dietary behaviors.

Methods: This is an interventional, prospective, and longitudinal study conducted in two general practice offices in the Hauts-de-France region. Participants were recruited in the waiting room and upon the suggestion of the physician or the researcher. They were asked to complete a questionnaire assessing their adherence to recommendations using the PNNS-MG score, adapted from the PNNS-GS2 score. Two weeks after receiving the brochure, participants were contacted again to complete the same questionnaire. An additional question was included to evaluate their satisfaction with the brochure, using a scale from 1 to 10.

Results: The analyses show a significant improvement in the score after reading the brochure, with a mean difference of +0.9 and a moderate effect size. The average satisfaction score was 8.1 out of 10.

Discussion: There is a significant improvement in adherence scores, and patients appear to appreciate the brochure. There was a large number of participants. The score used was a validated score. However there was a 39% loss-to-follow-up rate, as well as desirability and participation biases.

Conclusion: Although the effect size is modest, it should be interpreted within a public health context. Further work to explore potential ways to improve the quality of the brochure would be valuable.

Context: Lymph-oleiomyomatosis (LAM) is a rare and chronic disease that mainly affects women of childbearing age. It is characterized by the abnormal proliferation of smooth muscle cells in the lungs, which can lead to the formation of cysts and the destruction of lung tissue.

Methods: Descripcion

Originality: The patient presented with joint pain for no apparent cause. After diagnostic tests, AML was confirmed by high-performance computed tomography (CT) and lung biopsy. Joint pain was attributed to the disease due to the presence of cystic lesions in the lungs and histological confirmation of the disease. Test results: High-resolution CT scan: showed cystic lesions in the lungs compatible with LAM. Lung biopsy: confirmed the presence of smooth muscle cells in the lungs. Treatment plan: - Pharmacological treatment: sirolimus to reduce the progression of the disease and relieve symptoms. - Follow-up: to monitor lung function and detect possible complications.

Lessons learned and future implications: The most relevant problems that a patient with AML may present include: Recurrent pneumothorax: This is one of the most common complications, affecting approximately 69% of patients. It is characterized by repeated episodes of lung collapse that require medical intervention. Chylothorax: Present in approximately 23% of patients, it consists of the accumulation of lymphatic fluid in the pleural space. Hemoptysis: Approximately 20% of patients may present with blood in the sputum. Progressive respiratory problems Renal angiomyolipomas Other less frequent manifestations: Ascites (accumulation of fluid

in the abdominal cavity) Pleuropericcardial effusion Chiloptysis (sputum of lymphatic fluid) Chiluria (presence of lymph in the urine)

Discussion: Lymphangioleiomyomatosis (LAM) presents significant diagnostic challenges for several key reasons: Diagnostic challenges of AML Rarity of the disease: Overlapping of symptoms with common conditions. Variable clinical presentation. Radiological similarities with other cystic lung diseases Initial presentation as isolated pneumothorax Association with Tuberous Sclerosis Complex (TSC) Limited knowledge among healthcare professionals

Conclusion: This case highlights the importance of considering AML in the differential diagnosis of unexplained joint pain in women of childbearing age. A thorough evaluation and timely diagnosis are crucial to initiate appropriate treatment and improve patients' quality of life.

Clara RICART PLANAS, Marc ALBIOL-PERARNAU, Núria MORENO MORENO

Semfyc, Camfic, Barcelona, Espagne

Context: Chronic exposure to biomass smoke is a major contributor to obstructive respiratory disease in rural and resource-limited settings. In southern Costa Rica, many Indigenous Ngöbe-Buglé households rely on indoor wood-burning cooking fire, with minimal access to diagnostic tools or standard inhalation devices. This case illustrates how structural and environmental determinants shape the clinical management of chronic respiratory symptoms in a remote primary care context.

Methods: In May 2025, a 65-year-old woman living in a home with an indoor wood cooking fire experienced a mild bronchospasm during a domiciliary primary care visit in an Indigenous Ngöbe-Buglé settlement. She had recurrent bronchospasm, with suspected chronic obstructive pathology linked to prolonged wood-smoke exposure. No complementary diagnostic tests or inhalation spacers were available. The episode was clinically oriented as mild bronchospasm based on symptom assessment, chest auscultation with a stethoscope, and normal peripheral oxygen saturation measured with a pulse oximeter. Inhaled therapy were indicated. An improvised inhalation chamber was constructed using a small plastic water bottle: a lateral opening was created to insert the inhaler, and the bottle's mouthpiece served as the patient interface, reinforced with a bandage to reduce air leaks. Clinical information and photographs were collected with consent, focusing on relevant clinical and environmental information. Treatment was delivered despite material constraints, though the inability to confirm diagnosis or adress environmental triggers.

Originality: Although improvised spacers have been described in low-resource environments, reports grounded in Indigenous home contexts in Central America are scarce. This provides insight into how environmental exposures and inequities affect respiratory care.

Lessons learned and future implications: The case highlights the need for adaptable, context-sensitive solutions in primary care. It emphasizes acknowledging environmental determinants, patient education, and ethical responsibility to provide equitable care in structurally disadvantaged settings. Such approaches may be transferable to other remote or underserved populations lacking chamber devices.

Discussion: This experience underscores the gap between ideal evidence-based management and the practical limitations of marginalized environments, encouraging reflection on feasibility, equity, and the clinician's role in adapting care.

Conclusion: The case illustrates persistent inequities and shows how primary care clinicians can deliver essential treatments through creative strategies, informing broader discussions on equity in global healthcare.

Naila DE OLIVEIRA, Hugo FERREIRA RODRIGUES, Cezzane ALMEIDA, Marcos Paulo HUTCHISON, Julia De Paula PANZAN, De Melo MARCIO CRISTIANO, Nathália De Moraes LEBEIS NERY, Brenno B. Nery DE SOUZA CAMPOS

Faculty São Leopoldo Mandic, Araras, Brésil

Context: Person-centered anamnesis is vital for adolescent care in Primary Health Care, especially when pregnancy is suspected. Adolescents face stigma and limited confidential support, so empathetic communication is crucial. This reflection introduces an escape-room educational strategy to enhance person-centered communication and structured anamnesis skills in suspected pregnancy situations.

Methods: an escape room scenario was implemented in a PHC unit featuring a simulated 16-year-old adolescent with suspected pregnancy. Groups of eight to twelve students from multiple health disciplines conducted anamnesis using the SOAP (Subjective, Objective, Assessment, Plan) method. To progress through the escape room, students were required to establish rapport, explore the adolescent's narrative, identify psychosocial determinants, address confidentiality, and construct an appropriate care plan. Embedded clues guided learners toward essential elements of person-centered history-taking, therapeutic communication, shared decision-making, and cultural sensitivity. A structured advocacy inquiry debriefing followed the scenario.

Originality: Using escape-room methods for adolescent communication training in PHC is rare. This scenario reflects real practice by combining cognitive, relational, and contextual care elements. The immersive approach boosts engagement, teamwork, and collaborative problem-solving, supporting Family Medicine's focus on continuity, patient-centeredness, and community orientation.

Lessons learned and future implications: Participants improved their skills in sensitive anamnesis, managing expectations, and creating adolescent-focused plans while upholding confidentiality. Training needs remain in motivational interviewing, stigma reduction, and collaboration with adolescent health networks. Future improvements will add telehealth, long-term follow-up cases, and tools to measure communication and emotional readiness.

Discussion: The escape room significantly strengthened communication skills, cultural sensitivity, and clinical reasoning relevant to adolescent PHC. The structured debriefing promoted deeper reflection and application of evidence-based approaches.

Conclusion: This escape-room scenario proved to be a powerful pedagogical method for developing empathetic, person-centered anamnesis skills in adolescent PHC, reinforcing essential technical and interpersonal competencies for humane, high-quality care.

Context: Matching insulin injection timing with meals remains a challenge for individuals with insulin-treated diabetes (ITD) using multiple daily injections (MDI). Suboptimal timing may worsen postprandial glucose dynamics. Digital insulin-support devices such as connected insulin pen caps may enhance adherence and timing accuracy. This collaborative study between Primary Care and Endocrinology evaluated the clinical impact of using a connected insulin pen cap (Insulclock® v2.0) in real-world settings.

Objectives: To assess whether the use of Insulclock® v2.0 improves: Injection timing relative to meals, CGM-based metabolic

outcomes, and Patient-reported treatment experience.

Methods: A pragmatic multicenter, prospective, open-label observational study was conducted including a run-in week, a masked two-week phase, and a four-week active feedback phase. Injection timing and CGM metrics were automatically recorded. Meal events and rapid-acting insulin doses were analyzed using ROC methodology. Treatment satisfaction was measured using ITSQ and DTSQ questionnaires.

Results: Fifty-two participants were included (mean age 54.4 years; 56.6% women; 60.4% T1D; mean baseline HbA1c 7.91%). Sites included three hospitals and one Primary Care center. Comparing masked vs active phase: GMI: 8.1 → 7.8% (p=0.034) TIR (70–180 mg/dL): +5.0% (p=0.0054) TBR (<70 mg/dL): –0.74% (p=0.0015) TAR (>180 mg/dL): –5.3% (p=0.016) On-time injections improved from 45.5% to 54.4% (p=0.0017), and timing shifted from +5.6 minutes post-meal to –5.9 minutes pre-meal (p=0.023). ITSQ and DTSQ scores indicated reduced treatment burden.

Discussion: The integration of a connected insulin pen cap into routine diabetes care resulted in clinically meaningful improvements in insulin administration behavior and CGM outcomes. The shift toward pre-meal timing suggests behavioral change facilitated by digital feedback. Improvements occurred across both Primary Care and Endocrinology settings, demonstrating feasibility, scalability, and value in multidisciplinary diabetes management. These findings support the role of digital adherence tools as complementary strategies to optimize MDI-based therapy.

Conclusion: Insulclock® v2.0 improved insulin timing and glycemic outcomes while reducing perceived treatment burden in real-world practice.

(1) Ufr3s, Grand Fort Philippe, France
(2) Ufr3s, Lille, France

Context: Few studies have investigated the prevalence of feeding difficulties among children in the general population. These difficulties are estimated to affect up to 25% of children, according to Chatoor (2003), and up to 80% of children with neurodevelopmental disorders, as reported by Manikam.

Objectives: This study aimed to evaluate the prevalence of pediatric feeding disorders in a general population sample in France using the Montreal Children's Hospital Feeding Scale (MCH-FS).

Methods: The questionnaire included the MCH-FS, as well as additional items regarding child follow-up characteristics, age, comorbidities, and the presence of a previously known pediatric feeding disorder (PFD). Data were analyzed for the full sample and across subgroups according to MCH-FS score and PFD status.

Results: A total of 210 children were recruited through a self-administered questionnaire distributed in the general population. The MCH-FS demonstrated acceptable validity parameters, with a sensitivity of 65% and a specificity of 79%. Using the threshold score of 45, 27% of children screened positive, while only 12% had an existing diagnosis of PFD. Mean scores differed significantly between children with a diagnosed PFD and those without. Significant differences in comorbidities were also observed between children without a PFD and those with a previously diagnosed PFD.

Discussion: The MCH-FS appears to be a valid screening tool for identifying feeding disorders in children within the general population. Feeding disorders and PFDs seem to be underdiagnosed in the general population. Clinical data from the children should be collected to better characterize affected

individuals. This study presents a selection and participation bias. Moreover, the MCH-FS is a screening tool for pediatric feeding disorders and not a diagnostic test.

Conclusion: The MCH-FS appears to be a valid instrument for screening feeding disorders in children within the general population. Pediatric feeding disorders seem to be underdiagnosed, suggesting a need for improved identification and follow-up. Future studies should include clinical data to better characterize affected children. Despite potential selection and participation biases, the study highlights the value of the MCH-FS, which could be particularly useful in targeted populations, especially those with comorbidities.

ID 714- Optimizing Timing for Colorectal Cancer Screening Implementation

Petra BOMBEROVÁ KÁNSKÁ, Lumír VITHA

Canadin Medical, Prague, Tchéquie

Context: A multisite private provider in the XXX, introduced remote care in 2019 as a small pilot to test physician readiness and workflow feasibility. The COVID-19 pandemic rapidly expanded adoption and normalized telemedicine within primary care. When pandemic-related demand decreased, the organization needed to convert improvised remote services into a sustainable and clinically anchored component of routine care.

Methods: The six-year development occurred in three phases. 1. Adoption (2019–2020): identification of use cases, documentation standards, and support systems enabling safe remote care 2. Monetization (2021–2022): establishment of pricing structures, evaluation of sustainability, and creation of unified operational processes 3. Integration (2023–2025): development of a dedicated Virtual Clinic staffed by physicians working exclusively in structured remote care, fully linked to physical practices through shared documentation, standardized triage, referral pathways, and defined follow-up processes Data were collected on utilization, demographics, and operational performance. Strengths included organizational continuity and strong linkage between remote and physical care. Limitations involved uneven physician adoption, initial workflow variability, and minimal national benchmarks. Measurable outcomes included changes in capacity, accessibility, efficiency, and cost.

Originality: This is one of the first documented long-term implementations of fully integrated remote care in XXX primary care. Unlike pandemic-driven telemedicine expansions, this case establishes remote care as an autonomous and organized service line with defined staffing, governance, and quality processes. The Virtual Clinic model differs from typical hybrid setups by integrating remote care into all physical care pathways.

Lessons learned and future implications: Clear triage rules, shared documentation, and robust clinical governance were essential for safety and efficiency. Physician training and cultural acceptance were crucial success factors. Future priorities include expanding clinical scope, improving digital interoperability, and enhancing chronic care pathways.

Discussion: By 2025, remote care functioned as a stable service covering administrative tasks, triage, acute consultations, and chronic follow-up. Seventy-five percent of utilization came from urban areas. Integrated workflows increased overall capacity by approximately 33% and reduced costs by 9.2%, primarily through more efficient physician time use.

Conclusion: When systematically organized and fully connected to physical care, remote care becomes a sustainable medical discipline that increases capacity, improves access, and reduces costs in primary care systems.

ID 2263- Oral history as a tool for community based intervention and health improvement in older adults

Martin MARC

Faformec, Rouen, France

Context: The French Headache Society (Société Française d'Etudes des Migraines et Céphalées: SFEMC) published in 2021 the Revised Guidelines for the Diagnosis and Management of Migraine in Adults on Diagnosis and Assessment, then Pharmacological Treatment and wished to take into account and evaluate some Non-Pharmacological Treatments including Non-PharmacologicalInterventions (NPI), MedicalDevices and Surgery. Acupuncture method is one of non-pharmacological treatment.

Objectives: The development process consisted in five stages: 1) literature review within each writing sub-groups (writing group members and invited experts); 2) draft update within each sub-groups; 3) review of the whole draft by the writing group; 4) review by the reading group; 5) final editing by the writing group in the light of all comments.

Methods: The questions asked regarding NPI were: - Is physical exercise effective for migraine prophylaxis? - What is the evidence concerning,dietary supplements and plants? - What is the evidence concerning diets? - What neuromodulation therapies are effective in migraine? - What is the efficacy of acupuncture for migraine prophylaxis? -What is the efficacy of behavioral interventions and mindfulnesstherapy for migraine prophylaxis?

Results: Acupuncture for migraine management is recommended in several Clinical Practice Guidelines (CPG) : • Duodecim EBM Guidelines (Finland) 2022 • Istituto Superiore di Sanità (ISS, Italy) 2022 • Taiwan Headache Society (THS, Taiwan) 2022 • Committee for Clinical Practice Guideline for the Management of Chronic Pain (Japan) 2021 • Japanese Society of Neurology, Japanese Headache Society, Japanese Society of Neurological Therapeutics (Japan) 2021 • Australian and New Zealand College of Anaesthetists (ANZA) 2020 • Ministry of Public Health of Qatar (MOPH, Qatar) 2020

Discussion: Acupuncture for migraine management is recommended in several Clinical Practice Guidelines (CPG) : Since 2021, publication of a French CPG : Strength of Recommendation= Strong : "In patients with episodic migraine asking for non-pharmacological treatments or achieving insufficient efficacy with pharmacological treatments, propose acupuncture as an alternative or a supplement to pharmacological prophylaxis." But who knows this recommendation ? GP, neurologists ?

Conclusion: Acupuncture can be integrated into a multidisciplinary approach • Strong recommendation for migraine prevention • Interest for comorbidities management • Reduce drugs use • Safety • Respect of patient (and practitioner) values

ID 1209- Organization of Smoking-Cessation Groups in Primary Health Care within a Tobacco-Producing Municipality

Gaëlle RAGOT [(1)], Nadine PELLEN [(2)], Aziliz LE GLAZ [(2)]

(1) Département Universitaire De Médecine Générale-Université De Bretagne Occidental, Brest, France
(2) Spurbo, Brest, France

Context: La schizophrénie et la bipolarité font parties des troubles psychiatriques sévères (TPS) et concernent respectivement 0,4% et 2% de la population générale. L'espérance de vie de ces patients est réduite d'environ 13 ans en comparaison au reste de la population générale. Les pathologies cancéreuses représentent la deuxième cause de mortalité. Cependant, ils bénéficient plus rarement des programmes de dépistages organisés des cancers.

Objectives: Cette étude avait pour objectif de comprendre les représentations et les expériences des médecins généralistes concernant les patients présentant des TPS, ainsi que leurs effets sur la mise en œuvre des dépistages organisés.

Methods: Etude qualitative inspirée de la théorisation ancrée, menée à l'aide d'entretiens semi-dirigés auprès de médecins généralistes libéraux assurant le suivi de patients présentant une schizophrénie ou un trouble bipolaire. Les entretiens ont été enregistrés, transcrits et analysés selon une approche thématique inductive.

Results: Vingt-cinq entretiens ont été réalisés entre octobre 2023 et février 2024. Les médecins interrogés ont évoqué les difficultés rencontrées pour établir une alliance thérapeutique solide avec ces patients. Ils ont pu exprimer leurs représentations des TPS, ainsi que les obstacles spécifiques liés aux dépistages organisés. Enfin, l'étude a mis en évidence plusieurs élèments— tels que l'anticipation d'un refus ou la crainte d'une prise en charge complexe en cas de dépistage positif — qui pouvaient conduire à ne pas proposer systématiquement les dépistages organisés à tous les patients et de fait provoquer une sorte de sélection des patients à dépister.

Discussion: Les résultats de cette étude pourraient expliquer les difficultés d'accès au dépistage organisé rencontrées par ces patients. En revanche, ces inégalités d'accès ne semblent pas suffire à expliquer la différence de mortalité liée aux pathologies cancéreuses par rapport à la population générale. Les résultats confirme la nécessité d'un accompagnement personnalisé de ces patients. Evaluer l'impact d'une visite médicale de prévention systématique dès l'instauration de la prise en charge psychiatrique pourrait être particulièrement pertinent.

Conclusion: Cette étude a mis en lumière les représentations que les médecins généralistes avaient des patients présentant des TPS, ainsi que les conséquences possibles de ces représentations sur le dépistage organisé, pouvant conduire à une sélection des patients à dépister.

ID 109- Osteoporosis prevention in perimenopausal women; Screening and lifestyle prevention advice in primary care.

Silvia SÁNCHEZ CASCO, Pedro Alejandro GONZALES FLORES, Javier ESCAMILLA CANO, Daniel HUARTE NAFRIA, Amadeu DIAZ PRATS, Judith RIBAS REBULL, Montserrat PEDRA BENAIGUES

Spanish Society Of Family Medicine, Barcelona, Espagne

Context: Introducció: Una burocràcia excessiva en l'atenció primària pot provocar insatisfacció entre pacients i professionals sanitaris, reduint l'eficiència i la qualitat de l'atenció. Aquest estudi avalua l'impacte d'una intervenció de desburocratització en l'atenció primària.

Objectives: L'objectiu principal de l'estudi és avaluar l'impacte d'una intervenció de desburocratització en l'atenció primària en l'eficiència i la qualitat de l'atenció. Objectius específics: - Millorar l'eficiència de l'atenció, mesurada pel nombre de pacients vistos per hora. - Reduir el temps dedicat a tasques administratives. - Avaluar l'eficàcia d'assignar un coordinador, un metge i personal administratiu per resoldre les visites burocràtiques.

Methods: - Es va implementar un programa de desburocratització en 8 centres d'atenció primària, incloent: - Un metge coordinador diari que revisa horaris i resol visites burocràtiques (per exemple, resultats d'analítiques, receptes electròniques, cites duplicades). - Simplificació dels processos administratius. - Implementació de tecnologies de la informació i la comunicació (TIC). - Formació del personal en gestió del temps i priorització de tasques.

Results: Les dades obtingudes al llarg d'un mes es van comparar amb les dades obtingudes el mes anterior, treballant amb els mateixos professionals per evitar la variabilitat interprofessional. La intervenció va reduir el temps administratiu en un 30% i va augmentar l'eficiència de l'atenció en un 20% (mesurat pels pacients vistos per hora). El metge coordinador va resoldre una mitjana de 25 visites burocràtiques diàries, permetent als metges centrar-se en l'atenció clínica.

Discussion: Els resultats positius de l'estudi es poden atribuir a diversos factors: - Assignació d'un metge coordinador. - Assignar un personal administratiu competent - Ús de les tecnologies de la informació i la comunicació

Conclusion: La desburocratització en l'atenció primària és una estratègia eficaç per millorar l'eficiència i la qualitat de l'atenció. Assignar un metge coordinador amb suport administratiu ha estat crucial per implementar i mantenir el programa de desburocratització.

ID 56- Outcome of Early Insulin Administration on Anxiety Associated Newly Diagnosed Type 2 Diabetes Mellitus Patients: A Case Control Study

Venkatram NAVANEETHA KRISHNAN, Thanushree VENKATRAM

Knoll Medical Practice, London, Royaume-Uni

Context: Many of our patients have commenced GLP1 analogue injections for weight loss via private providers. As per NICE, GP must provide follow up care for 12 months after completion of treatment regime. We believe this increases in practice workload in future due to clinical monitoring and investigations in NHS practices

Methods: Aim: 1.Document number of patients are in weight loss injection from private providers. As per NICE recommendation 2. To check BMI recorded at least 12 months prior to start of the medications 3. To check any blood parameters are available within last 12 months 4. To formulate a pathway for future monitoring within surgery

Originality: The private letters received are checked and the medication is coded in patient records as hospital only prescription. This led to total of 190 patients are taking the weight loss injections. 50 are males and 140 are females

Lessons learned and future implications: 47 patients are treated in private sector. 3 diabetic patients are having injections via surgery. 18 are males and 32 are females. The age range is 24 years to 82 years. BMI recorded within 12 months prior to start of treatment is for 32 patients. 18 patients have no BMI recorded in last 12 months. There were few patients who are less than BMI of 30 are in these injection regime

Discussion: The coding of private letters has helped us to understand the perception of our patients willing to use the weight loss injections and it created a subset. Unfortunately, many of our studied patients have no recorded blood tests within last twelve months for liver, renal function, FBC and HbA1C as prerequisite for commencing GLP1 analogue injections for obesity management.

Conclusion: These patients are approaching NHS General practices for evaluation of adverse events as many private providers do not have proper mechanism for clinical monitoring and most of the patients are self paying for their treatment. It is important to maintain safety of our patients, so we have collabrated the use of technology by online self-reporting for monitoring the adverse events.This leads to better care in follow up of these patients.

(1) Arfae, Strasbourg, France
(2) Faformec, Rouen, France

Context: According to the French Public Health Code, every doctor undertakes to provide patients with conscientious, dedicated care based on scientific evidence, calling on the assistance of competent third parties where necessary. The practice of acupuncture in France is regulated and reserved for medical professionals, doctors and midwives. There are still misconceptions and a lack of knowledge about the validated indications for acupuncture. In a patient-centred approach, scientific literature shows that acupuncture can be a therapeutic option for many indications in general medicine

Methods: Analysis of the activities of a general practitioner who practises acupuncture and, based on feedback, reflection on the place of acupuncture in the therapeutic arsenal. Example of the management of migraine patients.

Originality: In certain cases, acupuncture can offer general practitioners a non-drug-based therapeutic response that is relevant, effective and safe.

Lessons learned and future implications: Acupuncture is an additional therapeutic option in general medical practices. It is

recommended by national and international professional guidelines for certain indications.

Discussion: Liberty, equality, fraternity! How can we offer access to care, including acupuncture, in a coordinated pathway? How can we strengthen exchanges between the various healthcare stakeholders?

Conclusion: Dispelling misconceptions Optimising access to healthcare as a whole without excluding a relevant approach. The validated indications for acupuncture should be better known to general practitioners.

Corresponding author: Camille Kintz-Chassard, dr.camille.kintz.chassard@gmail.com

ID 359- Overview of electric breast pumps prescriptions in France between 2014 and 2024 based on national health insurance open data.

Mayukh BHATTACHARYYA, Venkatram NAVANEETHA, Sokhun Solyndar Khun KHUN, Aneeq AHMED SHAIKH

Sangam Surgery E 12, London, Royaume-Uni

Context: Antimicrobial resistance (AMR) is a natural phenomenon that arises as microorganisms adapt and evolve, human activity also accelerates the process when antimicrobials are used inappropriately. The UK government has developed guidance regarding antimicrobial prescribing and stewardship (APS). As part of the APS competency framework, healthcare professionals are urged to perform antimicrobial prescribing audits and use the results to inform prescribing practices and improve patient care

Methods: Consultations at Sangam Surgery from October 13th- 31st 2025 was accessed via EMIS web. Basic information regarding patient demographics, presenting complaints (cough or sore throat), and consultation type (face-to-face or telephone) was recorded. Further information required to evaluate prescribing practices against NICE's URTI antimicrobial guidelines and the RCPG TARGET audit toolkits was also recorded. All data processing was performed on Microsoft Excel.

Originality: We aim to review prescribing practices of Senior doctors at our practice and one of the authors who was not involved in clinical care reviewed and analysed the data of patients presenting with acute coughs, and sore throats. Each set includes a graphic of the decision-making process for antimicrobial prescribing, followed by tables outlining the antibiotics of choice for different age groups.

Lessons learned and future implications: 19/65 of them not prescribed anything, 11 of them were prescribed back-up/delayed antibiotics, 35 of them were prescribed immediate antibiotics 34 /46 with appropriate antibiotic, dose, and duration. 46 of them were appropriately managed in regard to antimicrobials. 4/15 of them were not prescribed anything, 1 of them were prescribed back-up/delayed antibiotics, 10 of them were prescribed immediate antibiotics

Discussion: Use of NICE URTI prescribing guidance by all doctors in the practice . Choice of antibiotic, dose, and course length should always take into consideration the patient's demographics Documentation of clinical examinations and recording of fever, cough, tonsillar exudate, and cervical lymphadenopathy should be present in the notes Clinicians should discuss the Natural history and average length of their suspected infection b. Appropriate antibiotic use and the consequences of antimicrobial resistance

Conclusion: Advice given to patients and should include fluids, temperature control, and pain management and safety-netting documentation Encourage use of "Treating Your Respiratory Tract Infection" leaflet available via the RCGP TARGET website

Corresponding author: Mayukh Bhattacharyya, mayukh.bhattacharyya3@nhs.net

ID 250- Overview of parental knowledge on newborn's health in general practice

Victoria ELLIS, Carl DEANEY, Kelly DEAKINS

No, Lincolnshire, Royaume-Uni

Context: Ulcerative colitis (UC) increasingly requires shared-care delivery across primary& secondary services, yet rural health systems

face additional barriers including sparse specialist access, inconsistent monitoring infrastructure, and variation in capability. WONCA priorities emphasise continuity, equity, person-centredness, and strengthening the role of primary care in chronic-disease management—areas highly relevant to UC. This project integrated epidemiology, patient-journey insights, and healthcare-professional (HCP) learning needs to design pragmatic treat-to-target (T2T) maintenance& flare pathways for rural general practice.

Objectives: To combine real-world epidemiological evaluation, analysis of patient experiences, &assessment of HCP learning needs to co-produce structured UC pathways supporting personalised, equitable care in rural primary care.

Methods: Three workstreams were undertaken. 1. Epidemiology: A retrospective mixed-methods review of 64 adults with UC examined demographics, multimorbidity, disease-activity coding, biomarker utilisation, prescribing patterns, &referral behaviour. Qualitative free-text records underwent analysis to identify unmet needs/ barriers to care. 2. Patient Journey: Longitudinal review characterised relapse patterns, corticosteroid exposure, psychological burden, delays in biomarker testing, and difficulty accessing remote gastroenterology services—issues disproportionately affecting rural populations. 3. HCP Learning Needs: A digital questionnaire evaluated confidence, knowledge gaps, and preferred educational formats. Quantitative data were summarised descriptively; free-text underwent inductive analysis. Triangulation of the three data sources informed pathway development through multidisciplinary workshops aligned to NICE NG130, BSG guidance, &IBD-UK standards.

Results: The epidemiological review highlighted inconsistent disease-activity documentation, low utilisation of faecal calprotectin, and limited visibility of postoperative states. Patient-journey analysis revealed delays in recognising deterioration, inadequate safety-netting,& significant uncertainty about accessing specialist input. HCPs reported strong confidence identifying symptoms but limited confidence monitoring remission or managing flares; priority learning needs included differentiating inflammatory from functional symptoms, interpreting biomarkers,& safe steroid use.

Discussion: Integrating these findings enabled the co-design of two linked pathways: • A T2T maintenance pathway incorporating systematic biomarker-guided monitoring, structured coding,& optimisation of 5-ASA. • A flare pathway including early biomarker testing, rapid GP review, escalation criteria,& clear safety-netting information for patients.

Conclusion: A coordinated, mixed-methods programme integrating epidemiology, patient experience, and workforce development can strengthen UC management in rural primary care. The resulting pathways support WONCA priorities by improving continuity, reducing inequity, and enabling person-centred, proactive care across the chronic disease trajectory.

ID 115- Overview of the care and monitoring of people living with HIV by their general practitioners.

Alexis OELE

Dutch College Of General Practitioners, Utrecht, Pays-Bas

Context: The Dutch College of GPs (NHG) has been developing accredited e-learnings since 2007, based on NHG guidelines, to support implementation in daily practice. These e-learnings were originally designed for desktops/laptops and take up to two hours to complete. A 2022 survey among users indicated a need for shorter, mobile/tablet-friendly e-learnings, especially among younger GPs.

Objectives: To develop shorter e-learnings suitable for all devices.

Methods: In 2023, NHG launched a pilot to develop short e-learnings lasting no more than 30 minutes and suitable for all devices,

including smartphones.During development, we found these modules are most suitable for small, straightforward topics. Based on this insight, we created 10 e-learnings on subjects such as measles, scabies, head injury, herpes zoster, emergency care, and psoriasis. User experiences were evaluated through an online questionnaire.

Results: Evaluation occurred on two levels: - Content and process: We assessed feasibility and topic suitability during development. - User experience: Initial feedback from users was highly positive, particularly regarding the convenience of mobile access.

Discussion: Further quantitative evaluation—such as comparing usage rates of short versus traditional e-learnings—is planned. We are interested in the opinion from our colleagues abroad.

Conclusion: We are happy to share that developing concise, mobile-friendly e-learnings for GPs proved both feasible and valuable. By enabling learning on any device, we act for more liberty in professional development, ensuring equality of access for all practitioners regardless of location or schedule. Building on these first experiences, we will continue to expand and evaluate this format and invite international colleagues to join us in creating accessible, high-quality education for all.

(2) University Hospital Bratislava, Bratislava, Slovaquie
(3) Comenius University, Bratislava, Slovaquie

Context: Recommendations of international societies as well as the Standard Diagnostic and Therapeutic Procedures for Arterial Hypertension in Slovakia explicitly recommend measuring blood pressure in both upper extremities. A value of pressure difference higher than 10 mmHg is considered prognostically unfavorable in determation of cardiovascular risk. The symptomatic upper extremity peripheral artery disease is poorly studied compared with the lower extremity.

Methods: We describe the case of an 87-year-old woman, The case is an example of the long-standing ignoring of the recommendation regarding measuring blood pressure in both arms.

Originality: Patient with arterial hypertension, dementia, and adenocarcinoma of the uterus was repeatedly hospitalized for collapses in the last 10 years. The patient was a hairdresser. Her work was also her hobby and she practically until nowdays does hairstyles for her friends and neighbors. The pain in the right limb, which she reported during the last years both in the outpatient clinic and during numerous hospitalizations, was therefore quite logically attributed to right omarthrosis. During last hospitalization in the long-term care department was it found that the pressure difference between the right and left arm was 40 mmHg. Color duplex sonography and CT angiography were performed. The examinations confirmed critical stenotization of the right subclavian artery with the presence of subclavian steal syndrome. Subsequently the vascular team attempted to patency the stenosed right subclavian artery, but the calcified lesion resisted. The patient was discharged to the nursing house.

Lessons learned and future implications: In the discharge report, the general practitioner was alerted to inter arm pressure difference, which he must take into account in the management of arterial hypertension. A follow-up examination is planned with consideration of further intervention

Discussion: Health insurance companies in Slovakia reimburse preventive examinations every two years (blood donors every year). A self-evident part of the preventive examination should be measurement in both arms. Similarly, during the first visit to the department or hospital, in case of difficulties - dizziness, headaches and shoulder pain, or collapses.

Conclusion: This patient's story reminds us that the recommendation to blood pressure

measure in both arms is worthy of our attention in the interest of our patients.

ID 834- Parental perception of Use of steroid in atopic eczema – how to improve health literacy

Birkan BAYRAK, Oguz YESILLIOGLU, Nilgun OZCAKAR

Department Of Family Medicine, Faculty Of Medicine, Dokuz Eylul University, izmir, turkey, Izmir, Türkiye

Context: Basal cell carcinoma (BCC) is the most common skin cancer, typically arising in sun-exposed areas. It rarely metastasizes but may cause substantial tissue destruction through local invasion. Family physicians play a key role in recognizing non-healing skin lesions early and referring patients in a timely manner instead of prolonging unnecessary topical treatments.

Methods: E.N., a 73-year-old male, presented to family medicine with a 4–5-year history of a non-healing wound on the nasal dorsum that intermittently crusted and never fully resolved, requesting "an antibiotic cream prescription." Examination revealed a shiny nodular lesion on the nasal dorsum with a central ulcer/necrosis and prominent peripheral telangiectasias. Suspecting malignancy, the patient was referred to plastic surgery. Incisional biopsy confirmed basal cell carcinoma, followed by surgical excision and regular wound care.

Originality: This case is noteworthy in demonstrating that a long-standing lesion in a sun-exposed area, previously managed with multiple topical therapies, should not be repeatedly approached as a "simple infection" in primary care. Instead, a malignancy-oriented evaluation and timely referral can accelerate diagnosis and treatment.

Lessons learned and future implications: In primary care, all chronic, crusted, ulcerated, or unexplained bleeding skin lesions should prompt consideration of BCC and other skin cancers in the differential diagnosis. Family medicine training curricula should include practical education, algorithms, and encouragement of dermoscopy use for recognizing suspicious skin lesions.

Discussion: BCC is more common in older adults, individuals with chronic sun exposure and fair skin, and often presents on the face, particularly the nasal dorsum, as nodular, pearly, telangiectatic lesions. In this case, the 4–5-year non-healing course and resistance to repeated topical antibiotics were warning signs of an unfavorable healing pattern.

Conclusion: Family physicians should keep BCC in mind in long-standing, treatment-resistant nasal lesions and remember that timely referral to an appropriate specialty can prevent severe cosmetic and functional tissue loss.

(2) Nivel, Netherlands Institute For Health Services Research, Utrecht, Utrecht, Pays-Bas
(3) Department Of Epidemiology & Data Science Amsterdam Umc; Vrije Universiteit Amsterdam, Boelelaan 1117, Amsterdam, The Netherlands, Amsterdam, Pays-Bas
(4) Amsterdam Umc, Location Vrije Universiteit Amsterdam, Department Of Medicine For Older People, Boelelaan 1117, Amsterdam, The Netherlands, Amsterdam, Pays-Bas

Context: Mortality prediction models may support medical decision-making in older individuals. However, these models often involve manual scoring, are hindered by methodological issues, and their performance in persons with dementia is unknown.

Objectives: This study aims to leverage machine learning techniques in a large routine care database to automate identification of those with high mortality risks.

Methods: We utilized routine primary care data from a large nationally representative cohort of 355,958 community-dwelling older adults in

XXX. We developed three manually defined models, an automated machine learning model and a model including time series to predict 1- and 5-year mortality based on the electronic health record. A split-sample design was used evaluate discrimination and calibration, while using method specific internal validation procedures. Model performance was specifically assessed among individuals with dementia.

Results: The best models for both 1- and 5-year mortality were the time-series models with AUC-ROCs of respectively 0.861 and 0.846. Performance in people with dementia was lower with AUC-ROCs of 0.727 and 0.748. Calibration was good but slightly overestimated the risks for individuals with dementia. Although the time-series models performed best, there was no significant performance difference compared to the manually defined models.

Discussion: We developed accurate, interpretable, and potentially easily implementable models for mortality prediction based on routine primary care data in older adults. The model could help primary care physicians automatically identifying individuals at risk and facilitating timely advanced care planning, but external validation remains needed. Caution is needed when applying the model to persons with dementia.

Conclusion: This study demonstrates the feasibility of developing accurate, interpretable, and potentially implementable mortality prediction models using routinely collected primary care data. Our findings show that (electronic) primary health care records contain important predictive information, especially regarding diagnostic codes and contact information, and that they can contribute to automating individual risk assessments. However, the captured information varies among subgroups such as those with dementia. Following research should focus on the robustness of the models through external validation and the implications for practice.

ID 1155- Paresthetic Notalgia: A Case Report

Marine GRIGORYAN

Health For Armenia, Armavir, Arménie

Context: The project aimed to improve the care and continuous monitoring of patients with hypertension, increase their motivation, foster a responsible attitude toward health, and create a long-term monitoring system in two rural villages of XXX (V1 and V2).

Methods: Medical records in V1 revealed 45.4% of hypertensive patients had not visited the Center in three years. In V2, hypertensives were not registered in the Health Information System and did not receive necessary monitoring or treatment. The population lacked sufficient awareness about early signs and consequences, and many only visited a doctor when symptoms and complications arose. The family physician collaborated with nurses and directors of the health centers. Active identification, registration, and periodic monitoring of patients was implemented. Patients were invited to the respective Center, blood pressure measured, patient education provided, data recorded, and medications adjusted. Obstacles included lack of motivation among patients and lack of trust towards doctors. In V2 the existing records did not reflect reality.

Originality: According to WHO data, more than 7.5 million deaths occur globally yearly due to hypertension. A similar problem exists in almost all regions of XXX. This project ensured the development of a system for proper follow-up of hypertensive patients.

Lessons learned and future implications: Hypertension management requires not only pharmacologic management but also continuous communication/coordination, teamwork, and a systematic approach for data recording and analysis. Attention and individualized care make patients more motivated and responsible. For sustainability, patient visits will be organized every three months to prevent complications; awareness activities will be carried out; and data will be recorded for continuous monitoring. The

experience will be shared with other healthcare facilities for overall improvement.

Discussion: In V1, over 4 months, out of 50 previously uncontrolled patients, 23 visited the center, received consultations, medication adjustments, and follow-up monitoring, with all achieving control. In V2, over 3 months, 142 patients were screened, 56 hypertensives were identified (from a baseline of zero), received appropriate counseling and treatment.

Conclusion: Patients' attitudes were positively impacted, their trust increased, and health improved through continued collaboration. Community interest in healthy lifestyle increased, people began monitoring their diet, reduced salt intake, and regularly measure their blood pressure.

ID 1766- Participation in organized cancer screening among patients receiving opioid substitution treatment

Birkan BAYRAK, Halil SEHITLIOGULLARI, Nilgun OZCAKAR

Department Of Family Medicine, Faculty Of Medicine, Dokuz Eylul University, izmir, turkey, Izmir, Türkiye

Context: Diabetes mellitus is a common chronic disease, and early diagnosis is essential to prevent cardiovascular and microvascular complications. Family medicine practices follow high-risk individuals longitudinally and occupy a key position in diabetes screening. This case illustrates the consequences of omitting HbA1c and fasting plasma glucose (FPG) screening for years in a patient with multiple cardiovascular risk factors.

Methods: I.E., a 57-year-old man, presented to his family physician on 07.10.2025 for routine prescription renewal. As no biochemical tests had been performed for a long time, HbA1c and FPG were ordered, revealing HbA1c 14% and FPG 495 mg/dL; the patient was referred to the emergency department. He was hospitalized with insulin-requiring diabetes mellitus, acute kidney injury, and hyponatremia, and discharged after treatment. Retrospective review of electronic records showed that during the previous 5–6 years, he had been repeatedly seen in cardiology and other outpatient clinics with atherosclerotic heart disease, hypertension, hyperlipidemia, heart failure, and COPD, and had undergone four coronary interventions. No further diabetes screening had been performed after an HbA1c value of 5.9% in 2017.

Originality: This case demonstrates systematic neglect of diabetes screening in both primary and secondary care despite high cardiovascular risk and frequent healthcare encounters.

Lessons learned and future implications: Annual HbA1c/FPG screening should be standard practice for patients with risk factors such as coronary artery disease, hypertension, hyperlipidemia, and obesity. Electronic reminders and prompts within chronic disease follow-up forms stating "at least one HbA1c or FPG per year" may reduce delayed diagnoses and reinforce continuity and holistic care in primary care.

Discussion: Despite guideline recommendations for high-risk groups, workload and problem-oriented visits may lead clinicians to overlook screening, so diabetes may first be diagnosed in the setting of severe hyperglycemia.

Conclusion: Failure to use simple and accessible tests in a systematic way can delay diabetes diagnosis for years; strengthening screening processes may help reduce complications and the burden on healthcare systems.

ID 1106- Participative sciences in health : an active research project for improving women’s healthcare pathway

Charles TESSER

Ufsc, Florianópolis, Brésil

Context: Various complementary and alternative medicines (CAM) are allowed in the Brazilian Unified Health System (SUS). The Health Ministry, based on local experience, has financed a course of auriculotherapy - non-

invasive, with skin adherent plant seeds - for primary care (PC) professionals, since 2016.

Methods: The course is free and blended. The distance learning portion of the course (75 hours) is self-instructional, and in five modules: introduction; ear reflexology; auriculotherapy according to Traditional Chinese Medicine; auriculotherapy in science; clinical use in PC, and it ends with a 5-hour in-person practical lesson. Results from a 2023 research showed that 56.31% of the course's graduates practiced auriculotherapy after the course. The acceptance of auriculotherapy among users is high/very high (73.6%) and the effectiveness of the technique perceived by professionals is very high/high (79.72%).

Originality: The course is innovative in providing contextualized rapid training in PC clinical practice. 25 thousand professionals were trained, working in approximately 50% of the Brazilian municipalities. Auriculotherapy became the most performed CAM in the SUS. There is no similar case to compare.

Lessons learned and future implications: 1) Supported local initiatives can produce results on a large scale; 2) Professionals are open to learning CAM. 3) Some CAM, such as auriculotherapy, may enter professional training and on-the-job training needs to be disseminated.

Discussion: Do CAM have evidence of effectiveness and safety? Regarding auriculotherapy, good effectiveness is suggested by scientific evidence, although their quality is not good. This must be confronted with its great security, low cost, character of complementary therapy, additional security of auriculotherapy due to easy access, the longitudinality and biomedical expertise present, the great potential of its effect in most of the low gravity cases (greater potential for improvement due to self-regulation), the positive experience of the practitioners and great acceptance from users. This confrontation allows recommendations favoring the use of auriculotherapy in PC.

Conclusion: The course is a successful case of continued education, which made auriculotherapy the most performed CAM in SUS. This safe, cheap and easy-to-learn technique increases plurality and can reduce the iatrogenicity of care. The course could be translated and offered outside of Brazil.

(2) Department Of Endocrinology, Hedi Chaker Hospital, Sfax, Tunisie

Context: Obstructive sleep apnea–hypopnea syndrome (OSAHS) is a common respiratory disorder frequently associated with obesity and increased cardiometabolic morbidity.While continuous positive airway pressure (CPAP) is the standard treatment, nutritional assessment and management are still insufficiently integrated into routine clinical practice.

Objectives: To evaluate the nutritional status of obese patients with OSAHS and compare their clinical and polygraphic characteristics across two obesity levels.

Methods: We conducted a cross-sectional, descriptive, and analytical study in April 2024 at the Pulmonology and Endocrinology Departments of Hedi Chaker University Hospital, Sfax, including 40 adults with overweight or obesity (BMI ≥25 kg/m²) and confirmed OSAHS, who underwent a full dietary evaluation. Patients were grouped by BMI (group 1:<40kg/m²; group 2: ≥40 kg/m²). Clinical, polygraphic, anthropometric, bioimpedance, and dietary data were collected. Statistical analysis used SPSS 25, with $p < 0.05$ considered significant.

Results: The population was predominantly female (75%) with a median age of 56 years. Cardiometabolic comorbidities were frequent: hypertension (57.5%), diabetes (32.5%), and dyslipidemia (32.5%). All patients reported typical OSAHS symptoms. The median AHI was

22.55, and the median BMI was 37.7 kg/m², with 37.5% having morbid obesity. Mean daily energy intake was 2177.5 kcal, with 55.5% carbohydrates, 33.4% lipids, and 11% proteins; median fiber intake was 14.5 g/day, while calcium (402.4 mg/day) and iron (7.065 mg/day) intakes were below the recommended levels. Group 2 reported more insomnia (66.7% vs 32%, p = 0.033) and exertional dyspnea (86.7% vs 52%, p = 0.027), while polygraphic parameters showed no significant differences.

Discussion: In our study, OSAHS predominantly affected women ,with low exposure to tobacco and alcohol, reflecting Tunisia's sociocultural context. Nutritional assessment revealed severe obesity with excessive lipid and simple carbohydrate intake, and insufficient fiber and micronutrient consumption, dietary patterns that may contribute to OSAHS onset or progression. Morbid obesity was associated with higher rates of dyspnea and insomnia, but was not linked to increased AHI severity, consistent with previously reported inconsistencies in the relationship between BMI and polygraphic severity.

Conclusion: Obese Tunisian patients with OSAHS showed poor dietary quality and morbid obesity was associated with greater dyspnea and insomnia, highlighting the need for systematic screening and structured nutritional management.

Context: Diabetic nephropathy constitutes one of the foremost causes of end-stage renal disease. Health literacy plays a fundamental role in enabling effective self-care.

Objectives: To analyze the impact of a diabetic nephropathy educational video among individuals with diabetes and limited health literacy.

Methods: The study was conducted at a university-based diabetes outpatient clinic. Individuals with diabetes aged 18 years or older who attended the clinic during a two-week period in 2025 were invited to participate. A sociodemographic questionnaire was administered, followed by the application of the Health Literacy Assessment Test (HLAT). Participants then viewed a validated diabetic nephropathy educational video, after which the HLAT was reapplied without administrator interference. Questions 17 and 18 were excluded from scoring. Participants were classified as Level 1 (functionally illiterate) or Level 2 (functionally literate) according to their pre-test responses. Level 1 corresponded to questions 1, 3, 5, 7, 15 and 16 of the HLAT, while Level 2 corresponded to questions 2, 8, 10, 12, 13 and 14. Sociodemographic variables and tests scores were analyzed.

Results: Among the 21 individuals evaluated, 52% were women, with ages ranging from 27 to 79 years; among men, ages ranged from 42 to 77 years. Regarding years of study, 13 participants (62%) had incomplete primary schooling, 8 of whom were women. Additionally, 33% of the total sample had completed secondary schooling. Within the group with incomplete primary schooling, 31% (n = 4) were classified as Level 1, and 69% (n = 9) as Level 2. Those at level 1 had 1 to 3 correct answers and those at level 2 had 2 to 6 additional correct answers in the post-test.

Discussion: In country XXX (2024), among individuals with incomplete primary schooling, 51% achieved Level 1 and 19% reached Level 2 literacy. Level 1 participants were of particular interest for evaluating post-test changes, as HLAT performance at this level more effectively identifies limited health literacy.

Conclusion: Functional literacy classification positively influenced post-test performance among individuals with incomplete primary

schooling. Identifying limited health literacy and implementing strategies such as educational videos enhanced participants' understanding of disease processes, thereby supporting improvements in care provided to patients under follow-up.

ID 1267- Participatory Approaches in Primary Care: Challenges and Solutions

Erica Tania DAVILLO

Department Of Family And Community Medicine Perpetual Help Medical Center Binan Laguna Philippines / Philippine Academy Of Family Physicians / Armed Forces Of The Philippines / Harvard Medical School / Philippine Medical Association / Philippine College Of Occupational Medicine, Valenzuela, Philippines

Context: Neurofibromatosis (NF) is genetically inherited autosomal dominant disorder with incidence of 1 in 3,000 live births. Two types are recognized: NF1 and NF2, with NF1 being the most common. Solitary giant neurofibromas are rare and present significant surgical challenges due to extensive infiltration and high vascularization, often resembling normal tissue. These complexities are further compounded when patients present with nutritional risk, requiring holistic management.

Methods: A 50-year-old female patient diagnosed with NF1 and giant neurofibroma of the right lower posterior leg underwent total excision biopsy. Prior to surgery, comprehensive laboratory and imaging studies were conducted. Nutritional screening and assessment guided creation of tailored nutrition care plan, including daily food intake monitoring, oral nutrition supplements, multivitamins, and trace elements. Family members were actively engaged in preparing the patient physically and emotionally, ensuring adherence to the care plan and strengthening psychosocial resilience.

Originality: This case is distinctive for its integration of biomedical management with nutrition-focused interventions and family-centered psychosocial support. While surgical excision of giant neurofibromas has been documented, the deliberate prioritization of correcting undernutrition and mobilizing family involvement as active partners represents a novel multidisciplinary approach. It highlights equity in care by addressing both biological and psychosocial determinants of health.

Lessons learned and future implications: The case underscores nutrition as cornerstone of surgical readiness and emphasizes the role of family engagement in enhancing resilience. Future directions include advocating structured nutrition protocols in surgical pathways, strengthening community-based nutrition education, and embedding psychosocial support into perioperative care. These strategies align with 30th WONCA's theme liberty, equity, and fraternity.

Discussion: The successful outcome of this case illustrates how liberty in health achieved when patients are empowered through adequate nutrition, equity is advanced when multidisciplinary care addresses vulnerabilities, and fraternity is embodied when families and healthcare providers collaborate. It demonstrates that surgical success is not solely technical but deeply dependent on holistic preparation.

Conclusion: This case exemplifies how biomedical, nutritional, and psychosocial integration can transform outcomes in rare NF1 presentations. It advocates for liberty through patient empowerment, equity through comprehensive care, and fraternity through family and community solidarity, principles that resonate with 30th WONCA Eurooe Conference theme and global primary care values.

ID 1868- Patient advocacy in diagnosing an occult isolated posterior malleolus fracture: A case report

Hasmik AVETISYAN

Health For Armenia, Kapan, Arménie

Context: In this country, the mortality rate from diabetes is the highest in the region, with 50.9 cases per 100,000 population annually. In this Polyclinic, serving 38,000 patients, medical

staff's attention was focused on managing already diagnosed cases, with no measures for early detection and prevention. Previous years' data showed poor screening rates and low population awareness. The project aimed to increase early detection, enhance public awareness, and strengthen involvement and organization of the medical staff.

Methods: The response involved identifying and noting high-risk groups amongst 35-68 year-olds, introducing a mobilization method through calls by nurses to invite patients for screenings, and providing healthy lifestyle counseling. Obstacles included renovation of the polyclinic (which created accessibility issues, impacting screening numbers), people's fear of getting tested, or not considering it necessary. These were overcome by providing screening and counseling sessions in accessible rooms.

Originality: Quality Improvement and team-based care are very new concepts in this country. This project broke from the previous passive provider-dependent approach, ensured increased coverage and improved teamwork. Staff became involved in medical examinations as well as informational and organizational phases.

Lessons learned and future implications: The success of any prevention initiative depends on accessibility and trust. A personalized approach increases participation rates and creates a stronger connection. Community-based mobilization, active phone calls, and awareness-raising activities can become effective tools for the early detection of other diseases. For sustainability, the Polyclinic will establish a permanent screening schedule continuous training of healthcare workers, and ongoing community awareness activities.

Discussion: Screening rates increased from 23% in 2023-24 to 38% in 2024-25, despite two months with low numbers due to building construction. The screenings identified 20 cases of type 2 diabetes, and 18 cases of prediabetes, with some referred to endocrinology, while others were treated by their family doctor, based on state guidelines. Many patients noted that if it were not for this initiative, they would not have been screened, creating new levels of trust in primary health care in the community.

Conclusion: Data collection, adherence to planned schedule, and monitoring of results contributed to success. This community-based approach demonstrated that active population engagement can increase participation rates in screening.

(4) Family Medicine Resident, Aldenaueva De Ebro, Espagne
(5) Psychologyst, Aldeanueva De Ebro, Espagne

Context: A 14-month-old previously healthy girl living in a rural area was brought to a primary care facility. Her caregivers reported several months of progressive pallor, abdominal distension, irritability, constipation, night sweats and mild weight loss. They denied dog ownership or direct contact with dogs, although they lived in an environment where vector exposure was possible. Due to limited specialist availability and delayed consultation, the symptoms were initially attributed to recurrent viral illnesses.

Methods: Physical examination revealed marked pallor and non-tender hepatosplenomegaly. Initial laboratory testing yielded only a normal biochemical profile because the haemogram sample had coagulated. These reassuring results led the caregivers to believe that no further investigations were required. However, the discordance between the clinical findings and the incomplete laboratory information prompted repetition of the haemogram. The repeat analysis showed pancytopenia with a

leucoerythroblastic smear, leading to urgent referral for specialised assessment. Bone marrow aspirate demonstrated intracellular amastigotes, and polymerase chain reaction identified Leishmania infantum. The patient received liposomal amphotericin B with favourable clinical evolution, requiring an additional dose to address persistent splenomegaly.

Originality: Visceral leishmaniasis is considered uncommon in Europe, yet endemic transmission persists in certain Mediterranean regions, including areas of XXX. Importantly, infection can occur without direct canine exposure, illustrating the role of asymptomatic reservoirs and vector-mediated transmission. This case highlights how partial reassurance from incomplete testing and delays inherent to rural healthcare may obscure early recognition of severe disease.

Lessons learned and future implications: Key lessons include correlating physical examination with diagnostic decisions, repeating essential tests when clinical and analytical findings diverge, and considering epidemiological patterns when evaluating cytopenias and organomegaly. The case reinforces the importance of maintaining a high index of suspicion for visceral leishmaniasis in paediatric patients presenting with non-specific but persistent symptoms.

Discussion: Primary care plays a crucial role in detecting rare but clinically significant infections. Early identification of visceral leishmaniasis requires awareness of regional endemicity, recognition of non-specific presentations and a high index of suspicion when initial investigations are incomplete.

Conclusion: This case highlights the essential role of primary care in identifying rare but significant infections and demonstrates how structured evaluation and repeated testing can overcome diagnostic limitations in rural healthcare.

Camille KINTZ-CHASSARD [(1)], Marc MARTIN [(2)]

(1) Arfae, Ebersheim, France
(2) Faformec, Rouen, France

Context: Selon le code de la santé publique, chaque médecin s'engage à assurer personnellement au patient des soins consciencieux, dévoués et fondés sur les données acquises de la science, en faisant appel, s'il y a lieu, à l'aide de tiers compétents. La pratique de l'acupuncture en France est réglementée et réservée aux professions médicales, médecins, sages-femmes. Il existe encore des idées reçues et une méconnaissance des indications validées de l'acupuncture. Dans une approche centrée sur le patient, les données de la littérature scientifique montrent que l'acupuncture peut constituer une option thérapeutique dans de nombreuses indications en médecine générale.

Methods: Analyse de l'exercice d'un médecin généraliste pratiquant l'acupuncture et à partir du retour d'expériences, réflexion sur la place de l'acupuncture dans l'arsenal thérapeutique. Exemple de la prise en charge du patient migraineux.

Originality: La pratique de l'acupuncture peut offrir au médecin généraliste, dans certaines indications, une réponse thérapeutique non médicamenteuse, pertinente, efficace et sécure.

Lessons learned and future implications: L'acupuncture constitue une option thérapeutique supplémentaire dans les cabinets de médecine générale. Elle bénéficie de recommandations professionnelles nationales et internationales dans certaines indications.

Discussion: Liberté, égalité, fraternité ! Comment offrir un accès aux soins, y compris à l'acupuncture, dans un parcours coordonné ? Comment renforcer les échanges entre les différents acteurs de soins ?

Conclusion: Chasser les idées reçues. Optimiser l'accès aux soins dans leur globalité sans

exclure une approche pertinente. Les indications validées de l'acupuncture devraient être mieux connues des médecins généralistes.

(4) Izmir University Of Economics, Faculty Of Medicin, Izmir, Türkiye
(5) kutahya Health And Sience Univercity, Kutahya, Türkiye

Context: Workplace exercise programs are structured physical activity sessions implemented during the workday to promote musculoskeletal health, reduce sedentary behavior, and improve overall well-being. As modern work environments increasingly involve prolonged sitting and repetitive tasks, these programs have emerged as an accessible strategy to improve workers' physical and mental health.

Objectives: To summarize the benefits, implementation strategies, and impact of workplace exercise programs on employee health, productivity, and organizational outcomes.

Teaching method and workshop: Short lecture:20 minutes A narrative review of recent literature on workplace exercise interventions, focusing on musculoskeletal outcomes, mental health indicators, absenteeism, presenteeism, and employee satisfaction All group workplace exercases-20 min

Expected outcomes: Workplace exercise programs consistently demonstrate reductions in musculoskeletal pain—especially cervical, lumbar, and shoulder discomfort—and improvements in posture, flexibility, and functional capacity. Evidence also shows positive effects on stress

Conclusion: Workplace exercise programs are a low-cost, high-impact intervention that contribute to healthier work environments and improved employee performance. Integrating short, accessible physical activity routines into the workday can play a key role in promoting occupational health and preventing lifestyle-related conditions. Keywords: workplace exercise, occupational health, musculoskeletal pain, physical activity, productivity, health promotion.

ID 876- Pediatric Chest Pain: A Literature Review for Primary Care

Lin-Ya HUANG, Jason Jiunshiou LEE

Taipei City Hospital Yang Ming Branch, Taipei, Taïwan

Context: To address escalating care demands in a rapidly super-aged society and persistent post-pandemic hospital capacity constraints, XXX launched a government-led Hospital-at-Home (HaH) pilot program in July 2024.

Methods: The program enabled functionally dependent patients with urinary tract infection, pneumonia, or soft-tissue infection to receive intravenous antibiotics at home rather than in hospital. Our community-based public hospital enrolled 206 patients during the first 15 months of implementation, through which we identified practical issues involving eligibility criteria, antibiotic decision-making, and patient autonomy.

Originality: Among the 206 patients (mean age 80.19 years; 85 male, 121 female), 109 had urinary tract infection, 64 had pneumonia, and 33 had soft-tissue infection. A total of 37.37% were long-term care facility residents, and 36.4% were referred from the emergency department. The recovery rate was high (90.77%), while 7.77% were readmitted and 1.46% died. The mean duration of intravenous treatment was 6.87 days (SD = 2.31). Clinicians showed a preference for once-daily antibiotic regimens. In the subgroup of UTI cases, frequently prescribed agents included Amikacin (33.3%), Ertapenem (21.21%), and Ceftriaxone (21.21%).

Lessons learned and future implications: UTIs dominated admissions, a pattern inconsistent with national epidemiology. This may reflect restrictive pneumonia eligibility criteria within the pilot program; expanding these criteria could improve equitable access and overall program efficiency. Antibiotic choices were shaped not only by dosing convenience—critical in the context of limited nursing manpower—but also by pathogen profiles, resistance trends, and patient-specific risk factors. These insights underscore the need to align clinical pathways with the operational realities of home-based acute care.

Discussion: In practice, HaH functioned as more than a substitute for hospitalization. It reduced avoidable transfers for homebound patients, aligned with patient and family preferences for treatment in familiar settings, and lowered the risk of hospital-acquired infections. Delivering acute care at home also offered clinicians a clearer understanding of patients' daily environments and mobility constraints, thereby supporting more individualized care.

Conclusion: Our reflections suggest that HaH represents not only an alternative clinical pathway but a model that restores autonomy, preserves familiarity, and supports aging-in-place in meaningful and dignified ways which respects the rhythms of patients' daily lives.

ID 212- Perceptions and Attitudes of XXXXXX General Practitioners Towards Their Potential Role in Medical Assistance in Dying

Ana FAGGIOLI

Usf Águas Livres, Lisbon, Portugal

Context: Chest pain is a common presenting complaint among children and adolescents and accounts for a significant number of visits to Primary Care and Emergency departments. Despite its alarming nature for patients and families, pediatric chest pain is most often benign, frequently resulting in school absences, activity limitations, and heightened anxiety. A structured and informed approach in Primary Care can reduce unnecessary healthcare utilization and improve family reassurance.

Objectives: This literature review aims to summarize the current evidence on pediatric chest pain, focusing on epidemiology, common etiologies, and the role of the Family Doctor in clinical evaluation, diagnosis, and management.

Methods: A literature review was conducted using UpToDate and PubMed, focusing on publications from 2011 and 2012. The MeSH terms "chest pain" and "children" were applied to identify relevant studies addressing causes, frequency, and diagnostic approaches.

Results: In pediatric populations, chest pain is overwhelmingly benign, with only about 10% of cases associated with underlying organic disease. Musculoskeletal causes are the most common, while cardiac etiologies are rare even in chronic presentations. Chronic symptoms may recur every two weeks and persist for years without cardiac involvement. In the majority of cases, a thorough history and targeted physical examination provide sufficient diagnostic clarity. When the physical exam is normal or consistent with musculoskeletal origin, further diagnostic testing is generally unnecessary.

Discussion: Although the symptom often raises concern for serious disease—particularly cardiac pathology—the evidence indicates that most cases can be safely evaluated and managed in Primary Care. A holistic approach that includes family context, psychosocial contributors, and reassurance is central to reducing anxiety and preventing unnecessary referrals or investigations.

Conclusion: Pediatric chest pain is rarely cardiac in origin and can be effectively assessed by Primary Care clinicians through thorough history-taking and physical examination. Early recognition of benign patterns and appropriate reassurance support improved quality of life for patients and families while preventing overuse of healthcare services. Keywords: Chest Pain, Child, Adolescent

ID 1019- Perceptions of Hurtful and Comforting Words Related to Mental Health Among Primary Care Patients in Korea

Karolina KŁODA [(1)], Aleksander BIESIADA [(2)], Mateusz BABICKI [(3)]

(1) Polish Society Of Family Medicine, Szczecin, Pologne
(2) Polish Society Of Family Medicine, Gdańsk
(3) Department Of Family Medicine, Faculty Of Medicine, Wrocław

Context: Obesity and metabolic dysfunction–associated steatotic liver disease (MASLD) represent two of the most rapidly growing global health challenges, with significant implications for primary care. Family physicians are uniquely positioned to identify individuals at risk, initiate early interventions, and coordinate long-term management; however, many report limited confidence in diagnosing MASLD, interpreting non-invasive liver assessment tools, or integrating evidence-based obesity treatment strategies into routine practice. To address this gap, we developed a comprehensive education program aimed at enhancing family physicians' knowledge, diagnostic skills, and clinical decision-making related to obesity and MASLD.

Objectives: As Polish Society of Family Medicine we recognized the need to develop education strategies for family physicians based on current international guidelines and focused on translating emerging evidence into practical, patient-centered approaches.

Teaching method and workshop: We have designed online courses, performed webinars and prepared adequate materials. These included updated diagnostic criteria for obesity as well as MASLD and the MASLD–MASH spectrum, use of non-invasive tests such as FIB-4, liver elastography, and bioc

Expected outcomes: Improvement of participants role security and therapeutic committment through training. Not only in regard to peer to peer education but also to increase confidence in diagnosing obesity and MASLD, interpreting fibrosis risk scores, prescribing anti-obes

Conclusion: This education program equips family physicians with the competencies needed to recognize, prevent, and manage obesity-related liver disease more effectively. By strengthening primary care capacity, the initiative has the potential to reduce the burden of obesity, MASLD, improve patient outcomes, and promote earlier, more equitable access to evidence-based treatment.

ID 2258- Performance in the management of respiratory disease in PHC: an analysis of the organizational characteristics of health units in Portugal

Lidewij WIND, Marloes GERRITS, Karolien BREKEL

Leidsche Rijn Julius Healthcare Centers, Utrecht, Pays-Bas

Context: In the Netherlands, access to care for people with mental health problems is under pressure. Waiting times for patients are too long, psychological complaints are medicalized too easily, and there is insufficient collaboration between different levels of care. National parties have therefore established an Integral Care Agreement with commitments to provide care that fits the patient's needs in the most suitable setting, recovery-supporting practices with an emphasis on postitive health instead of illness, an integrated approach to psychological problems, and improved cooperation between general practitioners, mental health services, and social domain. Recovery-supporting care in general practice focuses on health rather than illness. This means moving away from the conventional medical disease model and DSM-based diagnostic thinking and instead creating space for the patient's story and for what he or she needs to recover.

Objectives: The recovery-supporting network intake, developed at UMC Utrecht by Prof. Dr. Floortje Scheepers, is a powerful method that can be effectively used in general practice to gain a complete picture of the situation and the unique story of the patient and their context.

Step by step, you work together with the patient to develop a tailored recovery plan, specifying which actor can contribute to support the patient. The result is increased patient autonomy, more collaboration and support from the patient's environment, greater involvement of the social domain, and referral to specialized mental health care only when truly necessary.

Teaching method and workshop: In this workshop, we will discuss the strengths of the network intake in everyday general practice. We will explain how the method works, and you will have the opportunity to practice using it.With the goal of being able to a pply this new approach in you

Expected outcomes: You will learn how to conduct a network intake with a patient

Conclusion: Working with the network intake is a powerful instrument with which you can help and guide the patient with mental complaints from strength and positive health instead of illness

ID 304- Periodic health examinations by general practitioners: waste of time or life-saving?

Gulnaz MOHAMOUD, Maureen KAMAU

Aga Khan University, Nairobi, Kenya

Context: Life expectancy has increased over the last century among older people, particularly those over 60 years. Aging is associated with increased disability, multiple chronic conditions and increased use of health services managed with polypharmacy. There are few studies on the knowledge and attitudes of patients regarding polypharmacy in XXX, hence it is unclear about the attitudes and what older people know about polypharmacy.

Objectives: The study aimed at obtaining an understanding of older people's knowledge, attitudes and beliefs about polypharmacy.

Methods: A qualitative study using in-depth interviews of 15 patients aged 60 years and older taking more than five medications per day. The study was conducted at the Family Medicine Clinic of the XXX University Hospital in XXX. Data were analysed using NVivo 12 software.

Results: Most participants had a good understanding of their underlying health conditions but could not recall the specific names of the medications they were taking. Participants had diverse attitudes toward polypharmacy, with both positive and negative perceptions. Although adverse side effects were being reported, participants remained positive because they believed these medicines were beneficial. Religion, faith and living healthy lifestyles were perceived to contribute to their positive attitude toward polypharmacy. Stigma and the cost of medications were reported as barriers.

Discussion: This study carried out in a private tertiary care institution, provided valuable insights into the complexities of polypharmacy in older people. It highlighted the importance of patient education, fostering strong patient-provider relationships, de-stigmatization of medical conditions and the need for improving medication affordability and accessibility.

Conclusion: Addressing the factors associated with polypharmacy can contribute to an effective and improved quality of life for older people managing polypharmacy. Further research could explore the knowledge, attitudes and beliefs regarding polypharmacy in older people attending public institutions in rural XXX

(4) Izmir University Of Economic, Izmir, Türkiye

Context: Loneliness, social isolation, and loss of meaning in life are increasingly recognized as drivers of chronic disease. Many patients present to family physicians with symptoms rooted in their social context, lack of purpose, and limited support networks. Drawing on Viktor Frankl's Man's Search for Meaning, this workshop highlights how purpose, belonging, and motivation influence health outcomes. Social prescribing, integrated with lifestyle medicine, provides a practical clinical approach to address these determinants. Link workers are essential in this process: they bridge healthcare and the community, personalize support, and maintain patient engagement, reducing GP workload and enhancing adherence.

Objectives: Participants will be able to: 1. Explain the synergy between social prescribing and lifestyle medicine in chronic disease management. 2. Recognize loneliness and loss of meaning as clinical issues. 3. Apply the ASSESS model to initiate social prescribing conversations. 4. Develop action plans integrating lifestyle advice, community resources, and potential referral pathways. 5. Identify strategies to overcome implementation barriers in primary care.

Teaching method and workshop: 10 min – Introduction & Setting the Scene Short presentation illustrating how social prescribing and lifestyle medicine complement each other. A clinical case (e.g., diabetes, isolation, poor diet) demonstrates how meaning and motivation shape outcomes. 2

Expected outcomes: Participants gain practical tools for integrating social prescribing and lifestyle medicine, understand the importance of meaning and connection in patient health, and learn effective collaboration with link workers.

Conclusion: By combining Frankl's meaning-centred approach with link worker support, family physicians can address loneliness, disconnection, and lifestyle challenges while improving long-term health outcomes.

ID 413- Persistent Headaches: When Obstructive Hydrocephalus Hides in Plain Sight

Vlad DALA [(1)], Radu SERBAN [(2)]

(1) The Heart Institute "niculae Stancioiu", Cluj-Napoca, Roumanie
(2) Pediatric Clinic I, Cluj-Napoca, Roumanie

Context: Pica syndrome is an eating disorder in which indigestible substances are repeatedly consumed, in this case soil. The number of hospitalizations due to the consumption of indigestible substances is increasing. Pica syndrome frequently occurs during pregnancy or in association with certain nutritional deficiencies.

Methods: A 2-year-old patient was referred to the pediatrics department of the Pediatric Clinic after experiencing abdominal pain and vomiting. The main reason for seeking medical attention was the ingestion of soil, as reported by the parents. The disease had begun insidiously several weeks earlier. The case was managed according to hospital protocol. Investigations revealed microcytic, hypochromic, iron-deficiency anemia, with no parasites present in the stool. An empty abdominal X-ray revealed radio-opaque material in the colon and rectum, as well as rectal ampulla distension. These results are suggestive of the ingestion of indigestible objects. Following interdisciplinary consultations in pediatric surgery and psychology, a diagnosis of constipation was made and an association with autism spectrum disorder was ruled out. Treatment consisted of enemas and oral administration of iron hydroxide-polymaltose complex. The patient responded well to treatment, with no notable complications.

Originality: Iron deficiency is commonly associated with Pica syndrome. In this case, the presence of gingivostomatitis was an early sign of eating disorder. The case was managed by a multidisciplinary team consisting of a pediatric gastroenterologist, pediatric surgeon, and psychologist.

Lessons learned and future implications: Diagnosing this condition requires a high

degree of suspicion on the part of the clinician. Parents need to be involved in supervising recreational activities and educating the child about behaviors that are acceptable or inappropriate for their age. X-rays are absolutely essential for evaluating patients with Pica syndrome.Despite autism being excluded, children still need comprehensive developmental assessments.

Discussion: This case of pica involving soil ingestion highlights diagnostic challenges and shares similarities with other non-nutritive eating behaviors across disorders presentations. Complications can have serious health consequences, such as intestinal obstruction or toxic effects of the substances.

Conclusion: A thorough investigation is recommended in such cases of eating disorder. Early identification and immediate correction of micronutrient deficiencies. The involvement of a multidisciplinary team can lead to favorable outcomes in the treatment of these cases.

ID 2131- Persistent hoarseness as an initial presentation of laryngeal cancer: A case report

María Isabel GUIRADO, Cynthia ANTEQUERA, Lorena MORALES

Servicio Andaluz De Salud, Almunecar, Espagne

Context: 56 years-old female patient with hipertension and hipothiroidism. Later on, we also discovered she's a usual alcohol drinker. Sent by his doctor for abdominal ultrasound, she refers symptoms of anroxia, asthenia, refluxes and billy vomiting for the lasta six months with hypertransaminasemia. No fever or infectious symptoms.

Methods: Ultrasound iin Primary Care: hepatomegaly and signs of chronic hepatopathy, moderate ascitis and splenomegaly that suggest portal hypertension.

Originality: The results of the ultrasound with the symptons and blood test results, we decided to send the patient to the emergency services in order to confirm the results and considerer hospital admission. The patient stayed for two months at the hospital where, she also had a liver biopsy and ended up being study in hematology service due to leukocytosis with neutrophilia, after an immunophenotype they found monocystosis at the expense of classical monocytes that suggests chronic myelomonocytic leukemia.

Lessons learned and future implications: Obviously, it was not in primary health care where all the estudies and the final dignose of the patient was done, but we did the ultrasound and found symptons of portal hypertension, that allowed us to submit the patient inmediatly to the hospital.

Discussion: So the ultrasound in our day to day practice is very useful resource that can help to detect patients that needs an urgent attention

Conclusion: If we couldn't have done an ultrasound in primary care, the diagnose of portal hypertension could have been delayed for months, so having acces to imaging studies as ultrasound as well as training family doctors in its use, is very valuable tool not only for the patient, but for the healthcare system.

ID 1294- Persistent Itching After Scabies Treatment: Avoiding Diagnostic Delay Through Sexual History-Taking: Case Report

Gulnaz MOHAMOUD, Florence MBATIA

Aga Khan University, Nairobi, Kenya

Context: Acute uncomplicated urinary tract infections (UTIs) are common, however, treatment is not optimal. Few studies on antibiotic use for specific diagnoses have been done in XXX. Information is sparce about prescribing patterns in the region.

Objectives: Outpatient management of urinary tract infections by medical officers in XXX.

Methods: The Aga Khan University hospital has 16 outpatient clinics in XXX run by medical-officers. A baseline assessment of evaluation

and treatment of suspected UTI was performed from medical records. A medical-officer from each clinic was recruited with eight randomised to control vs. feedback groups. Both groups were given a multimodal educational session (CME) including locally adapted UTI guidelines and emphasis on problems identified in the baseline assessment. Each record was scored using a scoring system that was developed for the study according to adequacy of history, physical examination, clinical diagnosis matching recorded data, diagnostic workup and treatment. Three audits were done for both groups: baseline (audit 1), post-CME (audit 2), and a final audit, which was after feedback for the feedback group (audit 3). Primary analysis assessed overall guideline adherence in feedback group versus the CME only group.

Results: Overall scores in both groups showed significant improvement after the CME in comparison to baseline and for each group, the scores in most domains also improved. However, audit 3 showed persistence of the gains attained after the CME but no additional benefit from the feedback. Some deficiencies included lack of workup of possible STI and excess use of non-UTI laboratory tests such as Complete Blood Count, stool culture and H. pylori Ag. After the CME, the use of nitrofurantoin rose from only 4% to 8% and cephalosporin use increased from 49 to 67%, accompanied by a drop in quinolone use.

Discussion: This study is one of the few in XXX to study the effect of A&F on physician adherence to UTI guidelines for doctors trained at the medical officer level.

Conclusion: This study has demonstrated the challenges in persuading physicians to use nitrofurantoin, the drug of choice for UTI treatment. The CME led to modest improvements in patient care in the categories of history taking, treatment and investigations.

ID 2038- Persistent pruritus in primary care: when a common symptom signals serious disease

Aleksandra TANAKA [1] , Alasdair PURVES [1], Elinor THOMAS [1], Bazargani MOSAB [2], Rebecca PAYNE [2]

(1) Cardiff University, Cardiff, Royaume-Uni
(2) Bangor University, Bangor, Royaume-Uni

Context: Drones are increasingly recognised for their potential to strengthen healthcare logistics, particularly in rural regions where long distances and challenging conditions delay diagnostics and care. In XXXXX XXXXX, 85% of patients registered with a general practice live rurally and rely on GPs as their first point of contact. Approximately 95% of clinical pathways depend on pathology services, yet sample transport can be limited with couriers typically visiting practices only once daily contributing to delays in timely diagnostics. Drone transport from GP-led community hospitals to laboratories could modernise pathology networks, reduce delays, and improve care for remote communities.

Objectives: (i) Model drone routes for pathology sample transport in the XXXXX XXXXXXXXXX XXXXXXXXXX XXXXXX XXXXX (XXXXX). (ii) Evaluate potential impacts on costs, transit times, and sustainability compared with current fleets.

Methods: GP-led community hospitals and pathology laboratories were mapped, including sample volumes and courier schedules. Drone routes were identified, and three scenarios were modelled: (i) business-as-usual van-only collection, (ii) partial drone adoption, and (iii) complete drone adoption. Outcomes included transit times, costs, and environmental impacts.

Results: Drone adoption is expected to substantially reduce transit times, particularly under full deployment, with significant CO2 savings from replacing diesel vans. Partial adoption offers more moderate improvements with smaller cost increases. Sensitivity analyses (e.g., weather conditions) highlight trade-offs: predicted benefits increase with rurality, but costs and potentially necessary high flight frequences may limit operational feasibility.

Discussion: Mapped drone routes suggest a feasible network for XXXXX. Drones offer substantial improvements to the efficiency and sustainability of pathology sample collection. Full adoption maximises time and emissions benefits but incurs higher costs. Partial deployment display more moderate gains with lower operational burden. Implementation would also provide opportunities for workforce redesign, enabling courier capacity to be redirected toward urgent or complex tasks. Engagement with communities, regulators, and clinicians will be essential to ensure acceptability, operational safety, and long-term scalability of any future drone-enabled service.

Conclusion: These findings highlight the feasibility and potential value of drones in rural primary care logistics, building a foundation to guide future pilot studies and service planning.

ID 1742- Pharyngeal barotrauma induced by suppressed sneezing with subcutaneous emphysema: a case report

Hanny YESHUA, Shira FERTIG HARARI

Family Medicine Departement Clalit Health Services Tel-Aviv District, Tel Aviv, Israël

Context: A 70-year-old woman, otherwise feeling well and appearing clinically stable, presented with persistent difficulty measuring blood pressure in her left arm in the last days. She also noted mild sensory changes in the same arm over several weeks but denied pain, weakness, or systemic symptoms. Her overall health seemed unchanged, making the inability to obtain a blood pressure reading her primary concern. This atypical presentation raised suspicion for underlying vascular pathology despite her reassuring clinical appearance. A broad workup was done, and a surprising diagnosis was made.

Methods: A detailed physical and neurologic examination was performed, revealing subtle asymmetry in the left radial pulse. Blood tests, including CRP and ESR, were normal, and ECG showed no acute cardiac findings. Differential diagnoses included both common vascular conditions such as atherosclerotic subclavian stenosis, subclavian steal syndrome and thoracic outlet syndrome as well as “can’t-miss” diagnoses such as large-vessel arteritis and early aortic dissection. Planned investigations included duplex ultrasonography and CT angiography. A central challenge was determining whether this workup could safely proceed in an ambulatory setting or required urgent evaluation in the emergency department due to the potential severity of underlying causes.

Originality: The case underscores the value of integrating careful bedside assessment with advanced imaging to detect uncommon vascular pathology in patients who feel entirely well.

Lessons learned and future implications: This case highlights that even benign-seeming complaints, such as difficulty obtaining a blood pressure reading in one arm, may indicate significant vascular disease. Subtle findings like unilateral blood pressure discrepancies, weak peripheral pulses, or sensory changes deserve thorough evaluation even in well-appearing patients.

Discussion: The primary dilemma involved choosing between ambulatory workup and emergency evaluation. While the patient appeared well, the risk of missing serious disease required careful triage and vigilance.

Conclusion: Unilateral blood pressure measurement difficulties warrant a broad differential diagnosis and timely vascular imaging to exclude conditions such as arteritis, subclavian stenosis, or aortic dissection, ensuring safe and effective management. Keywords:Blood Pressure Determination, Pulses, Giant Cell Arteritis

ID 1691- Physical Examination and Clinical Ultrasound: Keys to Diagnosing Occult Abdominal Masses in Primary Care

Samar ZAKI, Shazia MUHAMMAD WALI, Iffat AHMED

Aga Khan University, Karachi, Pakistan

Context: MRKH syndrome, or Müllerian agenesis, is a rare congenital disorder affecting 1 in 4,500–5,000 females, characterized by absence or underdevelopment of the uterus and upper two-thirds of the vagina, with normal 46,XX karyotype and secondary sexual characteristics. It is a leading cause of primary amenorrhea and poses diagnostic challenges in primary care. Early recognition and referral are essential to address reproductive, sexual, and psychological health needs.

Methods: A 20-year-old female presented to Family Medicine clinic with primary amenorrhea and normal secondary sexual development. Examination was unremarkable. Investigations revealed vitamin D deficiency; CBC, electrolytes, liver function, vitamin B12, TSH, and karyotype (46,XX) were normal. Pelvic ultrasound suggested absent uterus; MRI confirmed MRKH type 1 with uterovaginal aplasia, normal ovaries, and rudimentary Müllerian remnants. She was referred for

gynecologic evaluation, reproductive counseling, and psychological support. Strengths included early recognition and imaging; limitation was lack of long-term follow-up.

Originality: MRKH syndrome is rarely reported from XXX, especially in primary care. This case highlights the family physician's role in early identification and referral, the utility of MRI for detailed anatomical assessment, and the integration of reproductive and psychological care. Unlike many reports, this patient was asymptomatic aside from primary amenorrhea, with detailed documentation of ovarian morphology and Müllerian remnants.

Lessons learned and future implications: Primary care providers can facilitate timely diagnosis and multidisciplinary management, improving patient outcomes. Awareness and structured evaluation of adolescent females with primary amenorrhea can prevent diagnostic delays, allow early counseling, and support interventions for sexual and reproductive health.

Discussion: MRI remains the gold standard for anatomical assessment and management planning. Psychological support is crucial given the emotional impact of MRKH diagnosis. Multidisciplinary care, including gynecology, fertility counseling, and psychosexual therapy, is essential.

Conclusion: MRKH syndrome should be considered in adolescent females presenting with primary amenorrhea despite normal pubertal development. Early, structured evaluation, including MRI, enables accurate diagnosis, identification of associated anomalies, and timely multidisciplinary management. Integrating gynecologic care, fertility counseling, and psychological support enhances patient well-being, empowers informed decision-making, and ensures a holistic approach to sexual and reproductive health. Raising awareness in primary care can improve detection, optimize care pathways, and guide future practice in adolescent health.

Context: An effective surveillance program of drugs and addiction requires timely detection of emerging consumption patterns and new psychoactive substances. The time lag between conventional reporting systems and population-level perception creates a gap that can be more effectively addressed through sentinel networks.

Objectives: To advance the development of a drug-use sentinel network in Spain by building on our previously published study, focusing specifically on operational structure, implementation strategies, and the integration of digital tools and new technologies to enhance real-time surveillance.

Methods: A qualitative study was conducted between February and May 2025. A total of 13 regional, national and international experts in public health, drug policy, prevention, epidemiology, and digital technologies participated in three focus groups and four in-depth interviews. Data were analyzed thematically using ATLAS.ti, with triangulation of researcher data with adherence to SRQR guidelines to ensure rigor.

Results: Six categories and 16 subcategories were identified for the design of a sentinel network on drug use: (1) Definition and criteria for activating sentinel alerts; (2) Selection of key informants; (3) Communication of relevant signals and alerts; (4) Management and temporality of alerts; (5) National coordination of the sentinel network; and (6) Enabling factors for sustainability.

Discussion: The categories identified in the study reflect the complexity of designing a functional sentinel network for monitoring

drug use. The definition of alert criteria and the selection of key informants highlight the need for clarity and consistency to ensure reliable early detection. Effective communication pathways and clear temporal management of alerts are essential to prevent delays and reduce variability between settings. The emphasis on national coordination demonstrates the importance of a unified structure capable of integrating heterogeneous local contributions. Finally, the enabling factors identified—such as training, digital tools, and mechanisms to maintain engagement—underscore that sustainability depends not only on design, but on long-term operational support.

Conclusion: This work outlines the operational foundations for an effective drug-use sentinel system, emphasising clear alert management, robust coordination and digital support. Implementing these elements could improve real-time detection capacity and reinforce national surveillance infrastructures.

(1) Sangam Surgery, London, Royaume-Uni
(2) Newhamgpcoop, London, Royaume-Uni

Context: Children commonly present in primary care with varying degree of atopic eczema. Topical steroid and Emollients are regularly prescribed. We have also noted treatment failure in our clinical practice. This could be due to poor adherence with therapy. Lack of knowledge about the treatment of use of topical steroid, fear of real or imaginary side effects, under prescribing are the main causes of treatment failure.

Methods: We aim to audit the prescribing habits of 12 doctors randomly selected and independently assessed by one of the authors who was not involved in the treatment plan. We recorded the type of treatment offered. One patient was excluded from the study due to hospital shared care management. 61 patients under the age of 16, selected from practice database. 21/60 had weakly potent TCSs remaining had moderately potent steroid were used then All parents were invited to fill up dermatology quality of index via electronic messaging system to improve parents understanding and improve treatment adeherence

Originality: Original work under taken at Sangam Surgery. London UK

Lessons learned and future implications: All primary care physicians prescribed steroid/antimicrobial combinations than the constituent steroid alone. Parents reported lack of knowledge of the strength of topical steroid Dose used were twice a day. 60% Parents felt antibiotics would better that steroid.

Discussion: Practice based learning Parents and their carers must receive adequate information and training in how and when to use topical therapies in conjunction with written care plans or using electronic messaging system. The major cause of treatment failures in atopic dermatitis are multifactorials in this cohort. We found that Knowledge from social media had profound effect on use of Topical steroid. Many parents were afraid of side-effects from steroid use.

Conclusion: Parents were also gathered knowledge from social media. We have developed using NICE guidelines to educate the parents. Dermatology Quality of Index could address lack of knowledge about treatment, in particular the use of topical steroid therapy

Gulnaz MOHAMOUD [(1)], Bob MASH [(2)]

(1) Aga Khan University, Nairobi, Kenya
(2) Stellenbosch University, Cape Town, Afrique du Sud

Context: Background: Quality service delivery in primary care requires motivated and competent health professionals. In the XXX private sector, General Practitioners (GPs) with no postgraduate training in family medicine offer primary care. There is a paucity of evidence on the ability of primary care providers to deliver comprehensive care and no such evidence is available for GPs practising in the private sector in XXX.

Objectives: To evaluate GPs' training and experience in the skills required for comprehensive primary care.

Methods: A cross-sectional descriptive survey in 13 primary care clinics in the private sector. A questionnaire, originally designed for a national survey of primary care doctors in South Africa, was adapted. The selection of 78 clinical skills was based on the primary-care subset of clinical skills required in training of family physicians. Study collected self-reported data on performance of clinical skills by 25 GPs. Data were analysed in SPSS.

Results: GPs were mostly aged <40 years, with ≤10 years of experience, and there was an equal sex distribution. GPs reported moderate performance with adult health, communication and consultation, and clinical administration; and weak performance with emergencies, child health, surgery, ear nose and throat (ENT) and eyes, women's health, and orthopaedics. The GPs lacked training in specific skills such as proctoscopies, contraceptive devices, skin procedures, intra-articular injections, red reflex tests, and use of genograms.

Discussion: Majority of the GPs were young and not considering a career in family medicine. GPs performed poorly in some of the essential and basic skills required in primary care. A redesign of the health system's approach to gatekeeping and care pathways could encourage patients to obtain more cost-effective and accessible services at the primary care clinics. An important factor to consider would be incentives, such as fee-for-service, to motivate GPs to perform some of the procedures.

Conclusion: Comprehensiveness could be improved by deploying family physicians to the clinics, continuing professional development and postgraduate training in Family Medicine.A change in the scope of practice would also need to be supported by the organisation's infrastructure, equipment, supply chain, workforce, funding, and health information systems.

Context: This workshop introduces the concept of endocrine-disrupting chemicals (EDCs)—compounds that closely resemble our hormones but pose significant risks to human health. These ubiquitous chemicals are found in everyday products such as plastics, cosmetics and food packaging. While often overlooked on ingredient lists, EDCs and other toxics have far-reaching health consequences, contributing to conditions such as cancer, diabetes or obesity, amongst others, as well as affecting wildlife and disrupting ecosystems. This workshop emphasizes the importance of transparency in ingredient lists, calling for better public awareness and regulatory measures to mitigate the harmful effects of these hidden poisons. Understanding the true meaning behind everyday products' ingredient lists is crucial to protect public health and avoid paying the hidden costs of EDC exposure.

Objectives: To identify EDCs and other toxics components. To understand their effects in human and public health To foster informed choices to minimize the exposure and the impact on planetary health.

Teaching method and workshop: In a highly interactive setting with different stations, participants will uncover the ubiquity of EDCs and other toxic chemicals, through a dynamic escape-room structure. Working in groups, attendees will work together to solve puzzles, answer question g

Expected outcomes: Attendees will learn to identify EDCs and other toxic components, their health effects, and strategies for reducing exposure.

Conclusion: As primary care doctors, we must not forget about our communities health as a whole. We promise this workshop will inevitably change the way you live, think, and make choices. Are you ready to unveil the “ugly truth”? Come and join us!

(3) Acibadem University, Istanbul, Türkiye

Context: Diabetes mellitus presents a spectrum ranging from classical type 1 (T1DM) and type 2 diabetes (T2DM) to hybrid and atypical forms, including latent autoimmune diabetes in adults (LADA) and maturity-onset diabetes of the young (MODY). Accurate classification in primary care is challenging due to overlapping phenotypes, variable clinical presentations, and limitations of conventional diagnostic tools. Misclassification may lead to suboptimal treatment, delayed intervention, and increased risk of complications.

Objectives: Delegates will gain a better understanding of the following: Epidemiology and global burden of types of diabetes Pathophysiology of T2DM , T1DM and other types Diagnosis pitfalls and dilemmas Emerging role of CGM Early identification & Prevention – ‘a panacea’ for health systems

Methods: A narrative review was conducted using current literature from PubMed, MEDLINE, and primary care guidelines. Emphasis was placed on diagnostic criteria, biomarkers, and clinical features distinguishing T1DM, T2DM, LADA, and MODY. Case vignettes and algorithmic approaches were synthesized to illustrate decision-making pathways for ambiguous presentations.

Results: T1DM: Typically presents acutely in children or young adults, with hyperglycemia, ketonemia, and positive autoantibodies (GAD65, IA-2, ZnT8). T2DM: Common in adults with obesity, insulin resistance, and gradual onset; often associated with metabolic syndrome features. Intermediate forms (LADA, MODY): Display mixed phenotypes, slower progression of beta-cell failure, and variable autoantibody or genetic markers. Diagnostic tools: C-peptide measurement, autoantibody panels, and genetic testing improve classification but are not universally available in primary care. Algorithms combining age, BMI, clinical features, and laboratory markers improve diagnostic accuracy.

Discussion: Primary care providers often face dilemmas when diabetes does not fit classical definitions. Early recognition of atypical forms is essential to guide therapy—insulin initiation in T1DM or LADA, oral agents in T2DM, and targeted therapies in MODY. Clinical vigilance, combined with selective use of biochemical and immunological tests, can optimize outcomes. Challenges include cost, access to specialized testing, and the dynamic nature of diabetes progression.

Conclusion: Accurate classification of diabetes in primary care requires an integrated approach, balancing clinical assessment with targeted investigations. Awareness of intermediate and atypical forms, alongside practical algorithms, enhances diagnostic precision and ensures appropriate treatment initiation, ultimately improving patient outcomes.

(1) Université De Montpellier, Montpellier, France
(2) Chu Montpellier, Montpellier, France

Context: Several recent studies show that medical students are a population at risk in terms of mental health. In the 2018 government report by Dr. Donata Marra on the quality of life of healthcare students, it is recommended to "develop a genuine faculty policy that promotes student well-being and personal success." Thus, in 2024, the University Department of General Medicine of Montpellier-Nîmes redesigned the welcome day for first-year family medicine residents. The day was organized as a "scavenger hunt", allowing residents to discover emblematic locations within the Montpellier-Nîmes Faculty of Medicine and participate in various activities.

Objectives: The primary objective of this study was to understand the experience and assess the satisfaction of first-year family medicine residents who participated in an inovative welcome day. The secondary objective was to explore ways to improve this day.

Methods: A qualitative study using semi-structured individual interviews of first-year residents was conducted until data saturation. Interviews were analyzed by thematic approach. A descriptive quantitative study using a questionnaire was sent online to the same residents.

Results: Twelve interviews were conducted between December 2024 and February 2025. The results show that the first-year residents found the day enjoyable because they were able to have fun, share convivial moments, feel valued, and strengthen their sense of belonging to the faculty. It was also perceived as useful and supportive, fostering: the creation of connections, institutional reassurance, and a more serene start to their residency, both academically and professionally. The questionnaire responses were collected between December 20, 2024, and February 2, 2025. The questionnaire achieved a 68.61% participation rate. Statistics show that first-year residents appreciated the event and would like to participate again.

Discussion: This study highlighted the positive impact of such an welcome day on the mental health of general practice residents. Indeed, the literature confirms the presence of several protective factors for mental health that this day helped to activate, while also mitigating certain risk factors.

Conclusion: This pilot study is the first study to highlight the relevance of this type of mental health intervention within the residency program and encourages its development in other medical schools and among other student populations.

Context: Two-third of XXX cardiovascular disease (CVD) risk management is delivered in primary care practices via integrated care programs. Although these programs calculate individual risk for cardiovascular patients, risk stratification to identify patients for prioritized recall is currently not implemented. Given the anticipated staffing shortages and the substantial heterogeneity in primary care patients at risk of CVD, there is a need for optimizing this approach and promoting proactive organization of care. We therefore developed a multilevel complex intervention (PROSPERA) and explored barriers and facilitators of the pilot version in an early phase of implementation. The PROSPERA program comprises: 1) population-level risk stratification, 2) individual-level clinical

decision support tools and 3) remote patient monitoring.

Objectives: To explore anticipated and experienced barriers and facilitators by healthcare professionals when using the PROSPERA program in primary care.

Methods: We conducted 4 focus groups and 6 interviews with 9 general practitioners and practice nurses focusing on barriers and facilitators in current cardiovascular risk management and anticipated and experienced barriers and facilitators when using the PROSPERA program. After verbatim transcribing, interviews were coded inductively. Constructs of the Theoretical Domains Framework (TDF) were used for thematic analysis.

Results: Barriers and facilitators on three healthcare professionals' behaviours (providing proactive care, using clinical decision support tools and discussing outcomes) were found in 11 TDF-domains. Main barriers related to a lack of guidelines and know-how, pessimism on breaking habits, altered professional roles and limitations in technological infrastructure. Main facilitators related to beliefs about the value of proactive selection, the need for structural change, and optimism about clinical decision support tools contributing to improved comprehension, motivation and activation of patients.

Discussion: The PROSPERA pilot study adds to knowledge on barriers and facilitators in behaviour change of health care professionals when working with a complex intervention in primary care. To support further adoption of the PROSPERA program in clinical practice, healthcare professionals need further education and training, as well as support by restructuring the environment.

Conclusion: The insights of this study will be used for developing implementation strategies for a cluster randomized clinical trial. Results of the trial are expected in 2028.

Context: Creative health is an approach that recognises the positive impact of creativity and creative activities on our health and wellbeing. These activities span a wide spectrum, including the performing and visual arts, design and craft, literature, culture, and digital or electronic arts. Interest in the role of creativity in supporting both individual and community wellbeing has grown significantly in recent years. Evidence shows that taking part in creative activities can reduce mental distress, strengthen social connections, enhance quality of life, and support personal growth and empowerment. Creative health embodies the spirit of liberté, égalité, fraternité; fostering liberty of self-expression and empowerment. It promotes equality by making creative tools for wellbeing accessible to all, and strengthens solidatrity by building social cohesion and community support through shared creative experiences.

Objectives: The workshop objectives are that participants will: 1. Gain an understanding of the concept of creative health 2. Gain an understanding of how arts and creativity can impact health and wellbeing ourselves and our patients.

Teaching method and workshop: This workshop will use a variety of teaching methods ● an introductory slide-based presentation by co-authors ● demonstration of creative health in action e.g. GP poetry read-outs ● pair discussions and small group breakouts to discus

Expected outcomes: After attending, participants will be able to: 1. Apply the concepts of creative health to their clinical

setting, 2. Apply the concepts of creative health in their own lives

Conclusion: This workshop aims to equip participants with skills and confidence to apply creative health in their own setting, for themselves, their teams and patients. It will embody the ideals of liberté, égalité, fraternité, offering participants the freedom to express themselves creatively, promotoing equal access to well-being through the arts, and fostering solidarity through collaborative creative activities.

Amit GIBORI, Hanny YESHUA, Yael GILERMAN

Family Medicine Departement Clalit Health Services Tel-Aviv District, Tel Aviv, Israël

Context: Chronic Obstructive Pulmonary Disease (COPD) is a leading cause of morbidity and mortality worldwide and is frequently managed in primary care. Family physicians play a central role in early diagnosis, treatment initiation, inhaler education, and long-term follow-up. Despite clear evidence-based guidelines, gaps remain in optimal pharmacologic management, proper inhaler technique, and effective communication that supports patient adherence. This one-hour interactive workshop is designed to strengthen practical COPD management skills and provide family physicians with hands-on tools they can immediately apply in clinical practice.

Objectives: The primary objective of this workshop is to enhance the knowledge, confidence, and clinical skills of family physicians managing COPD. The session will focus on guideline-based treatment selection, correct inhaler technique, and motivational interviewing strategies to improve patient adherence and outcomes.

Teaching method and workshop: The workshop will be delivered through three rotating interactive stations, each approximately 15 minutes, followed by a brief summary: Station 1 - GOLD Guidelines & Evidence-Based Pharmacologic Treatment (15 min) - Review of the GOLD framework for diagno

Expected outcomes: By the end of this workshop, participants will: - Gain a clear understanding of current GOLD-based treatment strategies - Improve their ability to teach and assess proper inhaler technique - Strengthen communication skills using motivational interviewing

Conclusion: This practical, skills-based symposium equips family physicians with essential tools to improve COPD management in primary care. By combining guideline knowledge, hands-on inhaler training, and effective communication strategies, the workshop aims to support better patient outcomes and more confident clinical decision-making

ID 1305- Polycythemia vera presenting with aquagenic pruritus in primary care: a case report

Charles CAUET, Louis JABOURECK

District Of General Practice, Lille, France

Context: Complementary and alternative medicine (CAM) is increasingly used in Western countries. While the WHO encourages a regulated integration of CAM into health systems, general practitioners (GPs) remain cautious. Existing literature describes users' profiles, but little is known about their subjective experience. This study investigates how patients perceive and integrate CAM alongside conventional primary care.

Objectives: To explore the lived experiences, motivations and representations of patients who use CAM, and to identify the conditions enabling its safe and meaningful integration into patient pathways.

Methods: A qualitative study inspired by grounded theory was conducted between 2023 and 2025. Six semi-structured interviews were

recorded, fully transcribed, anonymised and validated by participants. Data were analysed using open, axial and selective coding with methodological triangulation among three researchers. The conceptual findings are synthesized in an explanatory model centred on trust, empirical reasoning, autonomy and biomedical anchoring.

Results: Patients assess CAM effectiveness through an empirical reasoning, relying on sensations and experiential evidence rather than scientific proof. They value "natural" treatments and express varying degrees of mistrust toward pharmaceuticals or perceived inconsistencies in conventional care. The therapeutic relationship is central: trust, availability, holistic attention and continuity of care reinforce adherence. CAM is embedded in a search for overall well-being, sometimes linked to cultural, spiritual or family dynamics. Participants emphasise the importance of the practitioner's biomedical training, seen as legitimising and reassuring. Some tensions appear regarding vaccination, scepticism toward the biomedical model or critical perceptions of pharmaceutical industries, all represented in the central analytic framework of the study

Discussion: Patients' recourse to CAM reflects a desire for meaning, personal coherence, and recognition in the therapeutic encounter. CAM practices serve not only as therapeutic techniques but also as symbolic resources shaping identity, autonomy and the patient–provider relationship.

Conclusion: CAM represents a complementary relational and symbolic dimension of care. Integrating it safely within primary care requires an open, structured and scientifically grounded approach by GPs, ensuring patient safety while strengthening the therapeutic alliance.

ID 967- Porphyria cutanea tarda in primary care: a case report

Jean-Claude LENERS

Gp Geriatrics Palliative Medicine Nursing Home For People With Dementia, Ettelbruck, Luxembourg

Context: As the number of patients with dementia is increasing, better awareness on how to treat them best is important.

Methods: I participated in a 60 ECTS, web-based learning in Karolinska Institutet Stockholm for 2 years.. It includes : cognitive and emotional functions of the brain; behavioural and psychological symptoms of dementia; the process for a suspicion of dementia; treatment, rehabilitation methods and palliative care. You have access to the tremendous library and to all journals related to dementia. As the physicians applying are from various countries and different medical working organizations, it allows a larger view on different care systems for people with dementia over Europe and farther. Strength of the course is the great flexibility in time to take part and the regular interactivity in the web online sessions ; limitations are a good fluent English needed , the necessary time-consuming amount for active participation and the high fees.

Originality: The innovative aspect is that this course can be done from home and allows you whenever to study, to write, but some hours are fixed for online exchanges. This master's degree is run every year since more than 8 years. The examination consists of evaluation during the different courses (individual or group works assigned and noted) and all participants must report on one specific topic related to their work for people with dementia and this has to be presented orally in the institution. After graduation, all GPs receive the title : "Silvia Doctor" and you are encouraged to continue in your country to promote the best medical treatment and care options.

Lessons learned and future implications: The fruitful contact with colleagues from other countries and the exchange in experiences is stimulating . Myself am dealing now mainly with dementia and palliation and we have established medico-ethical consultations for the end of life.

Discussion: Other countries have similar certifications and as GPs are visiting doctors in nursing homes for people with dementia, this can be an added value to become the medical coordinator.

Conclusion: I have still now contact with colleagues and we see us often in international congresses on this important and increasing topic.

Samar ZAKI, Nida IQBAL, Sania NAWAZ, Noorjhan MEMON, Sarah MANSOOR, Rabel KHAWAJA, Shaikh Jehanzaib SAEED

Aga Khan University, Karachi, Pakistan

Context: University students face substantial physical and mental health challenges linked to academic pressure, lifestyle changes, and communal living. These factors create diverse needs requiring timely preventive and curative care. Data from multidisciplinary universities in XXX remain limited. Understanding utilization patterns within structured student health services offering integrated care is essential for developing effective, student-centered systems.

Objectives: To examine three-year trends in Student Health Services (SHS) utilization at XXX University and identify priority areas for targeted interventions, preventive strategies, and resource planning to better meet students' diverse health needs.

Methods: A retrospective analysis of SHS records from January 2023 to November 2025 was conducted. Extracted data included visit volume, presenting symptoms, diagnoses, referrals, urgent care and Emergency Room (ER) utilization, and inpatient admissions. Analyses were stratified by academic program and year of study.

Results: A total of 19,115 student visits were recorded over three years (2023: 5,769; 2024: 7,410; 2025: 5,936). School of Nursing and Midwifery (SONAM) and Medical College students accounted for the majority of visits (45.4% and 44.6%), while Institute of educational development (IED) and Faculty of Arts & Sciences (FAS) contributed 2.4% and 7.4%, respectively. The most common concerns were upper respiratory infections, skin conditions, musculoskeletal issues, gastrointestinal complaints, and gynecological problems. Urgent care and ER visits totaled 1,869, largely from SONAM (42.6%) and MBBS (40%) students, with fever, respiratory and gastrointestinal illnesses, musculoskeletal pain, and headaches being the main reasons. There were 178 inpatient admissions or day-care procedures, and many students required counseling or psychiatric referrals, reflecting a rising mental health burden.

Discussion: The findings show varied healthcare utilization across programs, with high demand among nursing and medical students. Frequent infectious, musculoskeletal, and gynecological issues highlight physical health needs, while numerous mental health referrals indicate emotional and psychological pressures. These patterns underscore the need for preventive care, early identification of at-risk students, and better integration of physical and mental health services.

Conclusion: This three-year analysis highlights substantial and diverse health service use at XXX University, underscoring the need for robust, student-centered health systems. These findings can inform policy, optimize resource allocation, and support targeted interventions that strengthen student well-being and resilience.

(3) Department Of Clinical Pharmacology, School Of Medicine, Kyungpook National University, Kyungpook

National University Hospital, Daegu, Corée (République de)

Context: Proprotein Convertase Subtilisin/Kexin type 9 inhibitors (PCSK9i) such as alirocumab and evolocumab are increasingly incorporated into primary care lipid-lowering strategies. Recent reports, however, suggest potential short-term disturbances in glucose homeostasis. Evidence characterizing this risk in routine primary care settings is limited.

Objectives: This study assessed the short-term risk of hyperglycemic disorders following PCSK9i exposure and developed a time-series Long Short-Term Memory (LSTM) model to predict hyperglycemia using routinely collected clinical data.

Methods: A self-controlled case series (SCCS) design was applied to Observational Medical Outcomes Partnership – Common Data Model (OMOP-CDM) data from XXX Hospital. Incidence rate ratios (IRRs) were estimated for hyperglycemic disorders during PCSK9i exposure, with subgroup analyses for alirocumab and evolocumab and additional adjustment for concomitant hyperglycemia-inducing medications. Predictive performance of single-layer and two-layer LSTM models integrating longitudinal laboratory values and medication histories was compared with Random Forest and Logistic Regression models. SHAP analysis identified key predictors influencing LSTM outputs.

Results: PCSK9i exposure was associated with an increased short-term risk of hyperglycemic disorders (IRR 1.69, 95% CI 1.43–1.99). Evolocumab showed a significant association (IRR 1.75), while alirocumab showed a nonsignificant trend. The greatest risk occurred 121–150 days after exposure (IRR 2.38). The association remained after adjusting for hyperglycemia-inducing medications. The LSTM models achieved excellent predictive performance (AUROC 0.995 for single-layer; 0.998 for two-layer), outperforming Random Forest (0.969) and Logistic Regression (0.720). SHAP analysis indicated higher BMI, lower lipoprotein(a) and hemoglobin, and elevated creatinine and leukocyte counts as important contributors.

Discussion: Findings suggest that PCSK9i use in primary care may carry a short-term hyperglycemia risk, with agent-specific and time-dependent patterns that warrant clinical attention. The strong discriminatory performance of LSTM models highlights the value of temporal features in real-world risk prediction. These insights may support earlier identification of at-risk patients and guide primary care–oriented monitoring strategies.

Conclusion: PCSK9i exposure is associated with a short-term increase in hyperglycemic disorders, and LSTM models provide robust predictive performance with clinically meaningful risk indicators.

Daniela BASTO, Mariana FERREIRA, Sílvia COSTA, Beatriz ALBUQUERQUE, Andre FERNANDES

Usf Manuel Rocha Peixoto, Uls De Braga, Braga, Portugal

Context: Esophageal candidiasis (EC) is an opportunistic infection that typically occurs in immunocompromised individuals. We report the case of a 50-year-old immunocompetent man who developed EC to highlight the importance of recognizing it in otherwise healthy patients and identifying risk factors.

Methods: A 50-year-old man, with no significant medical history, presented with several weeks of chest pain during meals, postprandial fullness, and later, a foreign-body throat sensation. He had been taking a daily proton-pump inhibitor (PPI), and an increase in the dose to twice daily was suggested without improvement. An endoscopy performed one year earlier had been normal. Due to persistent symptoms, a repeat upper endoscopy with biopsy was performed, revealing multiple white plaques on the esophageal mucosa, consistent with EC, confirmed by histology. The patient was treated with fluconazole, leading to complete symptom resolution, and an evaluation for underlying immunosuppressive disorders was unremarkable.

Originality: This case describes EC in a healthy 50-year-old man, emphasizing other risk factors to this condition, other than immunosuppression.

Lessons learned and future implications: EC can occur in immunocompetent individuals, and a detailed clinical history can identify risk factors and raise suspicion. This diagnosis should be considered when risk factors are present and symptoms persist despite treatment.

Discussion: Candida species are responsible for opportunistic infections, and EC is typically associated with immunosuppression, as HIV infection, malignancy, or immunosuppressive therapy. In immunocompetent individuals, it is uncommon and can be associated with long-term acid-suppressive therapy, recent antibiotic use, or topical corticosteroids. Typical symptoms include retrosternal pain or odynophagia. Diagnosis can be made through endoscopic visualization of white plaques and confirmed histologically. Systemic antifungal therapy is the standard treatment, usually resulting in complete clinical recovery. In this case, no systemic immunodeficiency was identified, and the long-term PPI use was considered the most plausible risk factor.

Conclusion: It is important to be aware of the clinical presentation of EC and consider medication-induced alterations in mucosal defenses as potential contributors to fungal infections, even in immunocompetent individuals.

ID 2257- Practical implementation of lifestyle medicine in primary care consultations

Daniela BASTO, Mariana FERREIRA, Sílvia COSTA, Beatriz ALBUQUERQUE, André FERNANDES

Usf Manuel Rocha Peixoto, Uls De Braga, Braga, Portugal

Context: Myasthenia gravis (MG) is an autoimmune disorder characterized by impaired neuromuscular transmission, resulting in fluctuating muscle weakness and fatigability. We present a case of a middle-aged man diagnosed with thymoma-associated MG, highlighting the diagnostic challenges faced.

Methods: A 52-year-old man presented with progressive upper limb weakness, hand rigidity, and intermittent slurred speech. Despite the complaints, neurological and speech examinations were normal, as well as a cranial CT and upper-limb electromyography (EMG). Over several months, his symptoms persisted, with fatigability during sustained or overhead activities, prompting referral to Neurology. Meanwhile, he developed urgency urinary incontinence and was started on trospium chloride. Days later, he experienced worsening of symptoms, requiring hospitalization with evaluation that confirmed thymoma-associated MG.

Originality: This case describes an infrequent MG presentation, with limb-predominant episodic symptoms and initial normal investigations, leading to diagnostic uncertainty. It also reflects the impact of medication in exacerbating MG.

Lessons learned and future implications: MG may present with subtle symptoms and normal investigations, but fatigability should prompt consideration of neuromuscular disorders. Beware of medications that can exacerbate MG is crucial to prevent iatrogenic symptoms.

Discussion: MG is an uncommon disorder, typically affecting ocular or bulbar muscles. Limb involvement may also occur, affecting the upper limbs more than the lower limbs. In the early stages, symptoms may be episodic, but they worsen over time. Several medications can exacerbate MG symptoms and should be avoided. In this case, symptoms progressed over months, and despite the initial tests performed being normal, a neuromuscular disorder was suspected, and a Neurology referral was made. The introduction of trospium chloride, an antimuscarinic drug, contributed to a clinical worsening, leading to hospitalization and enabling the diagnosis

Conclusion: Family Doctors play a key role in the early recognition of many disorders. In this case, although a neurological condition was suspected, delays in specialist evaluation prolonged the diagnostic process. Additionally,

it highlights the importance of recognizing medications that can exacerbate myasthenic symptoms, ensuring safer and more effective management of patients with suspected or confirmed myasthenia gravis.

(1) Gp In Transgender Healthcare, Cambridge, Royaume-Uni
(2) Réseau De Santé Trans, Paris, France
(3) Viro Praxis, Hannover, Allemagne

Context: In UK 92% of patient population are registered at primary care practices. Primary Care is key to deliver assessment, treatment, continuing care, person centred care and preventive medicine to the general population. Primary Care is at the forefront to address health inequalities. NHS services is free and GPs are often the first point of contact for most people accessing health care irrespective of race, colour, sexual orientation, gender identity and economic background. Undocumented people are also able to register with a GP in the UK. In Germany 90% of the population are insured through health insurance companies. Access to Primary Care is available and every patient has a free choice of doctor. There has been a strong trend in the last few years towards Primary care with multidisciplinary (MDT} cooperation. In France primary care is mostly based on the Convention Nationale, with the specific objectives of improving coordination and quality of care, maintaining and improving access to care, respecting the choice of patients. Primary care coverage is universal and undocumented immigrants are covered through the State Medical Aid. Primary care workforce in France is self-employed with a growing tendency towards a comprehensive MDT team.

Objectives: There are different models of care where primary care worldwide has been providing gender care services in a friendly, safe, confidential, non- judgemental and accessible space both in person and online. The provision of care in a MDT setting is key to provide an excellent service with good clinical governance. The model of care has shifted from a psychiatric model, focussing on providing a comprehensive care. In the UK, Germany and France the wider primary care network plays a crucial role in supporting transgender people by providing ongoing hormone therapy prescriptions, routine general medical care, preventive health interventions such as cancer screening, and end-of-life care. An integrated IT system enables health care professionals to capture data to measure health inequalities and thus improving patients care.

Teaching method and workshop: roundtable discussion

Expected outcomes: Our workshop aims to share best practices to improve healthcare to trans people in a primary care setting.

Conclusion: Primary Care has the expertise to deliver healthcare to transgender population

Primary Care, Ávila, Ávila, Espagne

Context: Colorectal cancer (CRC) remains a leading cause of cancer-related morbidity and mortality worldwide. Early detection through screening significantly improves prognosis, yet adherence to preventive strategies remains suboptimal in many populations. Primary care plays a pivotal role in identifying alarm symptoms and initiating timely diagnostic pathways.

Methods: A 52-year-old male with a history of hypercholesterolemia and controlled hypertension presented to primary care with hematochezia, rectal bleeding, and altered bowel habits for eight months. He reported a 5 kg weight loss over two months and had previously declined CRC screening. Physical

examination was unremarkable except for blood on digital rectal examination. Laboratory tests revealed microcytic, hypochromic anemia; CEA 2.56 ng/mL and CA 19-9 19.21 U/mL. Urgent colonoscopy demonstrated an irregular rectal mass 3 cm from the anal verge; biopsy confirmed enteric-type adenocarcinoma. Staging CT revealed locally advanced disease. Neoadjuvant chemoradiotherapy was administered, followed by total mesorectal excision and terminal colostomy. Pathology: pT3 pN0 M0. Adjuvant capecitabine was initiated. Two years later, hepatic progression occurred, followed by pulmonary metastases surgically resected. The patient remains disease-free on surveillance.

Originality: Early detection through screening remains the most effective intervention. However, this case teaches that coordinated, multidisciplinary care can still offer meaningful survival and quality of life in advanced CRC.

Lessons learned and future implications: It emphasizes the need for persistent patient education in primary care to overcome screening refusal.

Discussion: This case illustrates the clinical consequences of delayed CRC screening. Despite presenting with classic alarm symptoms, the patient's initial refusal of preventive screening led to diagnosis at an advanced stage, requiring multimodal therapy and subsequent management of metastatic disease. Primary care providers are essential in reinforcing screening adherence and recognizing early warning signs such as hematochezia, unexplained anemia, and weight loss.

Conclusion: CRC screening is a cornerstone of early detection and improved survival. Primary care must emphasize patient education and adherence to screening protocols to prevent late-stage diagnoses and reduce the need for aggressive interventions. This case underscores the critical role of vigilance in primary care and the impact of timely preventive strategies on long-term outcomes.

(2) Amsterdam Umc, Amsterdam, Pays-Bas

Context: The health system not always aligns with the intrinsic drive of GPs to provide good patient care. For transformation to a future health system that better aligns, collective action is needed. Taking the liberty to initiate bottom-up change may provide a health system that allows for better patient care and being proud of one's profession. How GPs contribute to system change is not widely understood.

Objectives: This study examines GPs' perceptions on how they contribute to collective change in the health system. With a better understanding of the environment in which GPs contribute to change, we might be better equipped to aid (future) GPs in contributing to health system change.

Methods: Using purposeful sampling, we conducted individual interviews with thirteen GPs who contributed to change in the health system. Using the Rich Picture method, GPs first drew a situation in which they contributed to change in the health system. The use of a Rich Picture allowed for deeper reflection. Next, they elaborated on the environment where their contributions to change took place. We used an inductive and deductive thematic analysis informed by Cultural Historical Activity Theory, looking at the health system as closely linked environments that GPs work in.

Results: Most GPs became involved in changes in the health system because of tensions between the closely linked environments, that limited them in providing good patient care or being proud of their profession. Individual initiatives evolved into collective actions for structural change by making tensions debatable and urgent. Often someone helped them recognize the possibility of questioning

long-standing practises and taking action. Current GP training in the Netherlands was perceived to be less important for becoming change agents.

Discussion: This research shows how GPs initiate health system change by questioning long standing practices and co-constructing a new practice. GP training could do more to prepare (future) GPs for contributing to health system change.

Conclusion: Enabling GPs to contribute to health system change allows for improved patient care and proud professionals. Postgraduate training and continuing professional development that stimulate questioning current practices and make GPs' potential for change visible, may enable GPs.

ID 1793- Predictors for Early Detection of Dementia, the Importance of Testing and Early Identification of Mild Cognitive Impairment in the Practice of the Selected Physician

Hyang Ki CHO

Seoul National University Hospital, Seoul, Corée (République de)

Context: This is regarding an unsure, very ambiguous, yet not totally unlikely child abuse case that I confronted as a 2nd year family medicine resident. It was a very difficult case for me to take any definitive action, and I wanted to share this case with fellow primary care physicians and hear from them what they would have done.

Methods: I reviewed the clinical encounters, medical records, and growth and developmental history of a 27-month-old boy who presented with severe malnutrition and Salmonella sepsis. The case was analyzed in terms of mandated reporting, caregiver capacity, and potential consequences on rapport. I also reviewed patient's previous medical visits, emergency department records, and the circumstances surrounding the patient's mother's recent death to assess the likelihood of neglect versus contextual vulnerability.

Originality: This case highlights a rarely discussed dilemma in primary care: how to approach highly ambiguous yet concerning signs of possible child neglect when caregiver instability, recent family trauma, and limited social support complicate mandated reporting. Unlike typical child abuse cases with clear physical injury, this case involves chronic malnutrition, repeated missed follow-up, and contextual vulnerability after the mother's unexpected death, all factors that blur the boundary between neglect and inadequate caregiving capacity. A primary care perspective on such borderline cases is underrepresented in current literature, which focuses largely on emergency evaluations.

Lessons learned and future implications: The case highlights the need for clearer guidelines to support primary care physicians facing ambiguous child abuse cases. This case emphasizes the importance of early multidisciplinary collaboration, reliable social support pathways, and systems that prevent high-risk families from being lost to follow-up.

Discussion: Ambiguous suspected child abuse poses unique challenges in primary care, where the risk of damaging rapport must be weighed against the responsibility to report. Sharing similar cases may help primary care physicians refine responses to these ethically complex scenarios.

Conclusion: Making clear guidelines for ambiguous child abuse cases in primary care settings would be worthwhile.

ID 2140- Preliminary evaluation of biotinidase deficiency screening results in Igdir province: an ongoing retrospective analysis

Roxana CHIRUTA, Andreea NITA

Snmf Romania, Iasi, Roumanie

Context: Refusal of a medical act is one of the most complex ethical dilemmas in

contemporary practice, positioned at the intersection of patient rights, physician autonomy, and the moral obligations embedded in the therapeutic relationship. In family medicine—where continuity, trust, and long-term engagement define care—situations requiring a justified "no" may generate significant ethical tension. Increasing social, legal, and administrative pressure on clinicians further complicates these situations, making it essential to clarify the ethical boundaries of refusal to protect professional integrity and maintain high-quality medical care.

Objectives: To analyse the conditions under which refusal of a medical act is ethically justified in family medicine, to differentiate ethical refusal from abusive or discriminatory denial, and to propose a practical decision-making framework to support clinicians facing such dilemmas.

Methods: A narrative analysis of national and international literature was conducted, including WONCA statements, the Romanian College of Physicians' Code of Ethics, and key World Medical Association declarations. Three illustrative case scenarios from everyday family medicine practice were examined: requests for non-evidence-based prescriptions, patient demands conflicting with the clinician's moral or religious convictions, and expectations for interventions beyond the physician's competence or legal remit. These cases helped identify recurrent ethical criteria relevant to refusal.

Results: The analysis suggests that ethical refusal may be justified when the requested act contradicts scientific evidence or accepted standards of practice, poses a credible risk of harm to the patient or others, exceeds the physician's competence or legal authority, or conflicts with the physician's deeply held moral convictions, provided a reasonable alternative ensuring continuity of care is available.

Discussion: Ethical refusal emerges as a form of professional responsibility, ensuring that clinical decisions remain aligned with evidence, patient safety, and the physician's moral integrity. Maintaining transparent communication and offering reasonable alternatives allows physicians to preserve trust while upholding the ethical standards of family medicine.

Conclusion: Ethical refusal, when exercised within legal and ethical boundaries, represents a legitimate expression of professional judgment and respect for both patient welfare and the integrity of medical practice. A simplified ethical decision-making model is proposed to guide family physicians when a justified "no" constitutes the most responsible clinical response.

ID 342- Prenatal screening for Down syndrome : A review of current practices in the European Union

Meredith DONALDSON, Carl DEANEY

Marsh Medical Practice, Louth, Royaume-Uni

Context: People living with diabetes and chronic kidney disease (CKD) face a substantially elevated risk of atherosclerotic cardiovascular disease (ASCVD), yet uptake of lipid-lowering therapy (LLT) remains suboptimal across UK primary care.1 In the UK, high-risk primary prevention patients are defined as those with a QRISK3 score ≥10%, indicating a predicted 10-year cardiovascular risk ≥10% and representing the NICE-recommended threshold for offering statin therapy for primary prevention.2 Contemporary clinical guidance strongly supports proactive LLT initiation in diabetes and CKD. However, persistent treatment gaps, especially in rural and socioeconomically deprived areas, limit the effectiveness of ASCVD prevention efforts.3

Objectives: To assess the impact of integrating routine lipid testing into health checks, new-patient reviews, and long-term condition (LTC) reviews to improve LLT uptake among patients with diabetes, CKD, or QRISK ≥10%, and to compare performance against Primary Care Network (PCN) and national averages.

Methods: This quality-improvement initiative was conducted in a rural, deprived primary care practice. Lipid testing was incorporated into

health checks, new-patient assessments, and LTC reviews. Following testing, patients were reviewed by a clinician to optimise LLT, glycaemic control (HbA1c), estimated glomerular filtration rate (eGFR), and albumin–creatinine ratio (ACR) where indicated. Performance was evaluated using CVD PREVENT (June 2025), focusing on patients without diagnosed CVD but with QRISK ≥10%, diabetes, or CKD who received LLT.

Results: Practice LLT uptake: 76.62% PCN average: 57.44% National average: 56.98%

Discussion: Our practice substantially exceeded both local and national benchmarks.

Conclusion: Integrating routine lipid testing into LTC and new-patient reviews markedly increased LLT uptake within a high-risk population, despite the challenges of a rural, deprived setting. This model demonstrates a practical, scalable approach for family doctors aiming to close prevention gaps in ASCVD. The findings align with recent evidence emphasising the importance of proactive lipid optimisation in diabetes and CKD.1,2,3

ID 2089- Prescribing Change: The Physician's Guide to Effective Advocacy

Roxana CHIRUTA, Andreea NITA

Snmf Romania, Iasi, Roumanie

Context: Inflammaging—defined as chronic, low-grade systemic inflammation associated with aging—is a major underlying driver of multimorbidity, metabolic dysfunction, frailty, and early cognitive decline. Despite its increasing recognition in gerontology and immunology, there is no simple, clinically applicable method for assessing inflammaging in family medicine. Given the central role of primary care in prevention and management of chronic disease, a pragmatic screening tool is needed to identify patients at risk of accelerated biological aging and to guide timely lifestyle-based interventions.

Objectives: To develop and pilot-test a feasible, patient-friendly Inflammaging Risk Score (IRS) designed for routine use in family medicine consultations.

Methods: A cross-sectional feasibility study was conducted in a family medicine practice in Romania. Adults aged 35–75 years were assessed using the IRS, a 10-item composite score integrating anthropometric indicators (BMI, waist circumference), lifestyle factors (dietary quality, sleep duration, physical activity, smoking), stress, digestive symptoms (proxy for gut dysbiosis), and available laboratory markers (Vitamin D and CRP). Each domain was scored 0–2 (low/moderate/high risk). Primary outcomes were feasibility (completion time, ease of use), patient acceptability, and identification of predominant modifiable risk patterns.

Results: Fifty patients were included. IRS completion required 5–7 minutes, with 93% patient acceptability and full completion for all non-laboratory domains. The most frequent high-risk domains were: dietary inflammatory patterns, abdominal obesity, poor sleep, and digestive dysbiosis symptoms. Patients with ≥4 high-risk domains demonstrated higher prevalence of multimorbidity, including hypertension, dyslipidemia, and prediabetes.

Discussion: Both patients and clinicians reported that the IRS supported personalised discussions and increased awareness of modifiable risk factors. IRS may support structured preventive counselling, early stratification of multimorbidity risk, and implementation of personalised, lifestyle-based anti-inflammaging interventions in family medicine practice.

Conclusion: The Inflammaging Risk Score is a feasible, rapid, and clinically intuitive tool for identifying modifiable drivers of chronic inflammation and accelerated biological aging in primary care.

(3) 18/1812019, Motril, Espagne

Context: A 38-year-old male cyclist with a history of paranoid schizophrenia treated with Aripiprazole, obesity, and obstructive sleep apnea treated with CPAP, visited Primary Care Clinic in October 2024 for annual check-up, where a glycosylated hemoglobin (HbA1c) of 9.4% was detected.

Methods: Patient was then diagnosed with Type 2 Diabetes. Social environment and previous dedication to sports were explored and was encouraged to resume exercise given his strong motivation and family support. Treatment was initiated with semaglutide as there are articles (Ganeshalingam et al., Sass et al., or Manepalli et al.), where it´s been observed to improve glycemic control in patients with schizophrenia and antipsychotics without worsening psychiatric symptoms and improving adherence to treatment. Within 3 months patient resumed cycling and had considerably modified his habits. However, due to a lack of supply, semaglutide 1mg/ml subcutaneous once a week was replaced by semaglutide 14mg oral daily dosis, to which patient did not adhere. Nevertheless, tirzepatide was prescribed. Thanks to family support and after considering the economic burden it entailed, as this medication in not covered by Social Security, a significant improvement of HbA1c 5.4% by June 2025 was achieved. Medication was maintained until semaglutide SC could be restarted, upholding excellent control of his diabetes.

Originality: This case of successful metabolic control was achieved thanks to the combination of pharmacological and psychosocial factors, opting for a holistic approach and seen our patient as a whole, implicating much more than simply medication. Our purpose is to emphasize the importance of including all parts of our patients´ lives during follow up for a better and complete outcome.

Lessons learned and future implications: As Luciano et al. suggest, continued psychosocial support and exercise promote treatment adherence, helping both glycemic control and mental health in patients with these health problems.

Discussion: In Primary Care lack of time sometimes leads to prioritize pharmacological treatment, overlooking socioeconomic factors. However, in patients with mental illnesses, these factors can make a vast difference in treatment adherence and effectiveness.

Conclusion: The combination of pharmacological and psychosocial factors allows for glycemic control in complex patients, demonstrating, once again, that a comprehensive approach is key in the management of chronic illness.

(3) 18/1812019, Motril, Espagne

Context: An 86-year-old woman with a history of arterial hypertension, dyslipidemia, heart failure, glaucoma, anxiety-depressive disorder, and blindness (visual acuity in the right eye 0.05% and left eye 30%). She previously underwent cataract surgery. Current treatment includes sacubitril/valsartan, nebivolol, furosemide, and atorvastatin. No toxic habits. She presents to the primary care consultation due to visual hallucinations—seeing trees and flowers on the walls of her living room for the past two days.

Methods: The patient was conscious, oriented, without amnesic failures, and with coherent and fluent speech. Physical and neurological examination was unremarkable except for

reduced visual acuity. She had not started new treatments, nor had she suffered trauma or other neurological focality. Blood tests, serologies, urinalysis, toxicology screening, dementia tests, and a cranial CT scan were performed, all with unremarkable results. An ophthalmology consultation was requested, where fundus examination and macular optical coherence tomography were performed, with no relevant findings. The most likely diagnosis was Charles Bonnet syndrome.

Originality: Charles Bonnet syndrome (CBS) is a phenomenon characterized by vivid, complex visual hallucinations—well-defined, realistic images of objects or people—that occur when the patient is awake and mostly with eyes open, in individuals with visual impairment and no neurological deficits, as described by Rojas LC, Gurnani B et al. The most widely accepted current theory suggests that visual sensory deafferentation leads to disinhibition of cortical regions involved in vision, which results in spontaneous activation and produces hallucinations.

Lessons learned and future implications: This syndrome may go unnoticed and can be misdiagnosed as early dementia or psychosis. Cognitive dysfunction, social isolation, and sensory deprivation are the main causes of this syndrome, although other diseases and toxins may also be involved.

Discussion: CBS is widely underdiagnosed, and multidisciplinary involvement from different specialists is necessary.

Conclusion: Patients with this syndrome may experience fear. Psychological treatment and/or pharmacotherapy such as antipsychotics is recommended. In a patient presenting with hallucinations, a thorough examination and broad differential diagnosis must be performed to rule out any underlying neurological disorder.

ID 2030- Prevalence and severity of anxiety, stress, and depression among adults with long COVID in Barcelona: a cross-sectional study

Wan-Yi SHEN

Family Medicine Department, China Medical University Hospital, Taichung, Taïwan

Context: Malaria is rarely encountered in Taiwan, making early recognition challenging for primary care physicians. Travelers returning from endemic regions without prophylaxis remain at risk for severe Plasmodium falciparum infection. This case illustrates the importance of systematic travel history–taking and identification of red-flag symptoms in primary care.

Methods: A 66-year-old healthy man presented to primary care with five days of anorexia, fever, gastrointestinal discomfort, dark urine, and malaise after returning from the Congo. He had not taken malaria prophylaxis. Examination revealed jaundice, icteric sclera, and lower limb edema. Laboratory testing showed thrombocytopenia, acute kidney injury, hepatic dysfunction, metabolic acidosis, and coagulopathy. A malaria smear confirmed P. falciparum parasitemia. As his condition deteriorated with oliguria and respiratory distress, he was promptly referred for intensive care, artesunate therapy, and continuous renal replacement therapy. Strengths: Early recognition of severity and timely referral. Limitations: Lack of initial point-of-care testing and incomplete pre-travel counseling opportunities.

Originality: Severe falciparum malaria is rare in non-endemic regions like Taiwan, and few reports highlight its initial presentation in primary care settings. Unlike typical fever presentations, this case underscores multi-organ involvement occurring rapidly in a traveler without prophylaxis. The case adds to limited Asian literature on imported malaria requiring intensive care.

Lessons learned and future implications: This case reinforces the importance of routinely asking about travel history, recognizing red flags such as jaundice, dark urine,

thrombocytopenia, and early organ dysfunction, and providing pre-travel malaria prophylaxis counseling. Primary care protocols could better integrate travel screening and risk stratification for febrile patients.

Discussion: Febrile returning travelers require a broad differential diagnosis. Severe malaria can mimic common viral or gastrointestinal illnesses but rapidly progresses to life-threatening complications. Early suspicion, diagnostic testing, and urgent referral are essential in primary care.

Conclusion: This case highlights the critical role of family physicians in early recognition of severe malaria and the importance of preventive travel counseling. Timely referral and appropriate management can prevent mortality in imported malaria cases.

Hyang Ki CHO [(1)], Jiwon YU [(2)], Sang Min PARK [(2)]

(1) Seoul National University Hospital, Seoul, Corée (République de)
(2) Seoul National University College Of Medicine, Seoul, Corée (République de)

Context: As primary care physicians, we advise patients to quit smoking. However, BMI gain often follows smoking cessation, and managing the potential negative impacts of BMI gain also falls within our clinical responsibilities. Meanwhile, Alzheimer's dementia and vascular dementia are growing disease entities that are major concerns among elderly patients. It has not been clarified whether BMI changes following smoking cessation influence the risks of Alzheimer's or vascular dementia. Therefore, we conducted a retrospective cohort study to investigate this association.

Objectives: To clarify the association between BMI changes following smoking cessation and the risks of Alzheimer's dementia and vascular dementia

Methods: We performed a retrospective cohort study using a nationwide health screening database that included 224,588 adults aged 40 years or older who underwent health screenings between 2009 and 2012. Smoking behaviors were self-reported, and BMI changes were calculated over time. Our primary outcomes were overall dementia, Alzheimer's dementia, and vascular dementia, which were tracked until the end of 2019. Primary outcomes were defined using the International Classification of Diseases codes along with outpatient clinic and hospital admission records.

Results: Never smokers showed a significantly lower risk of dementia compared to continual smokers (aHR 0.85, 95% CI 0.73-0.97). Compared to quitters with minimal BMI change (net BMI change < 1.0), quitters with BMI gain (BMI change ≥ +1.0) showed a reduced Alzheimer's dementia risk (aHR 0.52, 95% CI 0.29-0.93). Further stratifying BMI gain (+1.0, +2.0, +3.0 or more) did not change this trend of reduced dementia risk.

Discussion: BMI changes did not significantly alter the general beneficial impacts of smoking cessation on dementia risks. Also, when compared among quitters, BMI gain was associated with further decreasing dementia risks, and this pattern remained consistent even with substantial BMI gain (≥+3.0). This aligns with previous literature that has demonstrated protective effects of late life BMI gain against dementia.

Conclusion: Primary care physicians should confidently advise patients that smoking cessation reduces dementia risk, and that BMI gain may even provide further benefits, especially for individuals aged 65 years or older.

ID 1385- Prévalence du prédiabète en médecine de première ligne en Tunisie : résultats de l'étude nationale TUN-PREDIAB

Dania ALMOKHTAR

University Hospital Southamptom, Southampton, Royaume-Uni

Context: Patients receiving biological therapies or JAK inhibitors for rheumatological conditions have an increased risk of herpes zoster. UK guidance (September 2023) recommended shingles vaccination for severely immunosuppressed adults aged ≥50. National uptake between September 2024 and February 2025 remained low, with 21.5% receiving one dose and 13.1% completing both doses.

Objectives: This audit aimed to evaluate local compliance with shingles vaccination among immunosuppressed patients aged ≥50 on biologics or JAK inhibitors and compare uptake with national data, identifying gaps and targeting quality improvement initiatives.

Methods: Single rheumatology centre review of hospital and primary care electronic records was conducted for patients aged 51-69 years who had been prescribed biological therapies or JAK inhibitors for at least the previous 6 months. Patients were excluded if age ≥70y or if primary care vaccination records were not available.

Results: 70 patients were included. Diagnoses were RA (n=30), axial SPA(n=29), psoriatic arthritis (n=10), and undifferentiated inflammatory arthritis (n=1). Treatments were adalimumab (n=25), etanercept (n=11), baricitinib (n=7), tocilizumab (n=5) upadacitinib (n=4), certolizumab (n=3), secukinumab (n=3), infliximab (n=3), golimumab (n=2), ixekizumab (n=2), rituximab (n=2), abatacept (n=1), bimekizumab (n=1) and guselkumab (n=1). 34/70 (48%) patients received at least one vaccine. 24/70 (34%) patients had written documentation of advice to have the vaccine in a clinic letter, of whom 19/24 (79%) received a vaccine. 46/70 (65%) patients had no advice documented in clinic, of whom 16/46 (34%) received a vaccine. One patient was told by her GP practice that she was not eligible for vaccination despite a rheumatology clinic letter recommending vaccination.

Discussion: Shingles vaccination uptake in this cohort of rheumatology patients aged 51–69 receiving biologics or JAK inhibitors was nearly 50%. Although suboptimal, this exceeds the national average for severely immunosuppressed patients (21% for one dose). Documented clinic-to-GP recommendations were strongly associated with higher uptake (79% vs 34%). Higher rates locally may reflect routine vaccination counselling within clinics.

Conclusion: Further work is needed to understand barriers to vaccination and to enhance uptake, particularly in light of the expanded eligibility criteria. Targeted education for patients, primary care, and secondary care teams is likely to support sustained improvement.

Context: Camellia oil is traditionally regarded as a health-promoting dietary oil in Asian populations, particularly for its potential benefits to metabolic balance and gastrointestinal function. Its fatty acid profile is similar to olive oil, which has been shown to improve lipid metabolism and support weight regulation. However, scientific evidence regarding the clinical effects of camellia oil remains limited.

Objectives: This study aimed to investigate the impact of long-term camellia oil consumption on body mass index (BMI) in adults.

Methods: This prospective self-controlled study initially enrolled 36 participants aged 20 to 75 years who agreed to consume camellia oil daily as part of their regular diet. Subjects were instructed to use camellia oil for cooking while maintaining their usual dietary patterns and lifestyle, without adopting other weight-loss interventions. After six months, two participants were excluded due to incomplete follow-up, leaving 34 individuals for final

analysis. BMI was measured at baseline and at the end of the six-month intervention. A paired t-test was used to compare changes in BMI before and after camellia oil consumption. The study was approved by the Institutional Review Board of Tungs' Taichung MetroHarbor Hospital (IRB No. 113039), and all procedures complied with the principles of the Declaration of Helsinki.

Results: The mean baseline BMI of the 34 participants was 24.25 ± 6.15 kg/m². After 6 months of continuous camellia oil consumption, BMI decreased to 23.15 ± 4.15 kg/m², reflecting an average reduction of 1.10 kg/m²; however, this change did not reach statistical significance (p = 0.075). Although a downward trend was observed, no serious adverse events were reported, and overall adherence to the dietary protocol was satisfactory.

Discussion: Six months of camellia oil consumption was associated with a slight reduction in BMI; however, this change did not reach statistical significance (p = 0.075). Furthermore, the flavour of camellia oil might affect appetite, which, in turn, influences weight.

Conclusion: While a downward trend was observed, the effect remains inconclusive and should be interpreted cautiously. Larger, well-designed randomized controlled trials are required to determine whether camellia oil exerts a clinically meaningful impact on body weight regulation.

(4) Division Of Renal Medicine, Tungs' Taichung Metro Harbor Hospital, Taichung City, Taïwan

Context: Camellia oil is commonly regarded as a functional dietary oil with potential cardiovascular and metabolic benefits. While it is frequently used for health promotion in Asian populations, clinical evidence regarding its effects on serum lipid levels remains limited.

Objectives: This study aimed to evaluate the impact of six months of regular camellia oil consumption on lipid profile parameters in adult participants.

Methods: This prospective self-controlled study enrolled 36 adults who agreed to use camellia oil for daily meal preparation while maintaining their usual dietary habits and lifestyle. Two participants were excluded due to incomplete data, leaving 34 subjects for final analysis. Fasting blood samples were collected at baseline and after six months to measure triglycerides (TG), total cholesterol, high-density lipoprotein (HDL), and low-density lipoprotein (LDL). Paired t-tests were applied to compare pre- and post-intervention lipid values. The study protocol was approved by the Institutional Review Board of Tungs' Taichung MetroHarbor Hospital (IRB No. 113039), and all procedures were conducted in accordance with the Declaration of Helsinki.

Results: This prospective self-controlled study enrolled 36 adults who agreed to use camellia oil for daily meal preparation while maintaining their usual dietary habits and lifestyle. Two participants were excluded due to incomplete data, leaving 34 subjects for final analysis. Fasting blood samples were collected at baseline and after six months to measure triglycerides (TG), total cholesterol, high-density lipoprotein (HDL), and low-density lipoprotein (LDL). Paired t-tests were applied to compare pre- and post-intervention lipid values. The study protocol was approved by the Institutional Review Board of Tungs' Taichung MetroHarbor Hospital (IRB No. 113039), and all procedures were conducted in accordance with the Declaration of Helsinki.

Discussion: Six months of camellia oil consumption did not result in statistically significant alterations in serum lipid parameters among adult participants. Although minor fluctuations in triglycerides and cholesterol

levels were observed, the overall metabolic impact on lipid profile appears limited. Further randomiszd controlled trials with larger sample sizes are needed to determine whether camellia oil exerts meaningful clinical effects on lipid metabolism.

Conclusion: It might be possible that the effect of camellia oil was not as practical as the oriental people thought.

Context: Cardiovascular disease (CVD) remains a leading cause of morbidity and mortality among older adults. Although the benefits of physical activity are well established in younger populations, evidence in adults aged ≥75 years is limited, particularly in real-world primary care settings. Understanding whether physical activity continues to provide cardiovascular protection in very old adults is highly relevant to family medicine and healthy ageing.

Objectives: To examine the association between weekly physical activity—measured using metabolic equivalents (METs)—and the risk of incident CVD in adults aged ≥75 years, accounting for death as a competing risk.

Methods: We conducted a nationwide cohort study using the Korean National Health Insurance Service database. A total of 869,524 adults aged ≥75 years who completed health screening between 2012 and 2015 were included after excluding those with previous myocardial infarction, stroke, or missing data. Weekly METs were calculated from standardized questionnaires and categorized into quartiles (Q1=lowest, Q4=highest). The primary outcome was incident CVD (myocardial infarction or stroke). Subdistribution hazard ratios (sHRs) were obtained using competing risk regression models adjusted for demographic, socioeconomic, lifestyle, and clinical factors.

Results: Over 5.6 million person-years, 126,686 CVD events occurred. CVD incidence decreased from 20.44 per 1,000 person-years in Q1 to 17.26 in Q4. Higher weekly METs were associated with progressively lower CVD risk (sHR for Q4 vs Q1: 0.84; 95% CI, 0.83–0.85; P for trend <0.001). Regular exercise also reduced CVD risk (sHR 0.86; 95% CI, 0.85–0.88). Cumulative incidence curves showed early and persistent separation across METs quartiles (Gray's test <0.0001). Subgroup analyses demonstrated consistent associations across sex and comorbidities, with attenuation only among adults aged ≥85 years.

Discussion: Physical activity demonstrated a clear, graded, and clinically meaningful reduction in CVD risk among very old adults. The persistence of benefit up to age 85 highlights the importance of maintaining activity even in advanced age. These findings support primary care interventions promoting safe, sustainable physical activity among older patients

Conclusion: Higher physical activity levels were independently associated with lower CVD risk in adults aged ≥75 years. Physical activity remains a key protective factor in healthy ageing and should be actively encouraged in primary care practice

ID 2168- Preventable drug interactions in primary care: An evaluation through three representative cases

Michael TAROUX, Katia MAZALOVIC, Claire ZABAWA, Julien MORISSON, Eleanor PAZART, Raphael GALEA, Maeva ABDALLAH, Valentin VERMEE

Département De Médecine Générale, Dijon, France

Context: Cardiovascular risk (CVR) assessment in primary care relies on scoring tools that primarily consider biomedical factors and rarely incorporate individual socioeconomic

characteristics, even though such associations have been clearly demonstrated.

Objectives: This study aimed to describe the level of CVR in primary prevention using three validated tools in French primary care patients and to analyze the association between socioeconomic characteristics and CVR level.

Methods: A cross-sectional study was conducted in two French primary care centers in the XXX region. We included adults aged 40–69 years without previous cardiovascular events from January to February 2022. Sociodemographic data, socioeconomic indicators (education level, employment status, French Universal Healthcare Scheme coverage, EPICES score), CVR factors, and clinical/biological parameters were collected using medical records. Ten-year CVR was estimated by SCORE2, Framingham, and Globorisk scores. The socioeconomic characteristics of patients with and without calculable CVR were compared. Then, we analyzed the socioeconomic characteristics of patients classified at a high CVR with at least one score.

Results: Among 578 patients screened, 478 were included. CVR was uncalculable for 20%, mostly due to missing biological data. These patients were younger, more frequently professionally active and had a lower educational level. Overall, 1.9% (Globorisk), 6.7% (SCORE2) and 17.1% (Framingham) were classified in the highest CVR category. High-risk patients were more often male, older, retired, and with lower education.

Discussion: This original project provides pragmatic data for everyday primary care practice. Despite the departmental nature of the study, the large sample size, the collection of data using medical records, and the concomitant use of several scores reinforce the validity of the results. Education level emerged as the main socioeconomic indicator associated with both high CVR and absence of risk assessment. Patients with unfavorable socioeconomic profiles require specific attention, beyond the risk estimated by these tools. Efforts are needed to optimize the identification and individual benefit of treatments in precarious populations.

Conclusion: Integrating socioeconomic parameters into risk assessment tools could improve the targeting of preventive interventions in primary care and promote care equity.

ID 1184- Preventing Memory Loss: Putting Prevention Into Action in Primary Care

Leticia RODRIGUES FIGUEIREDO SILVA, Rafael KAFURI BONACOSSA, Lorraine REGO SANTIAGO

Rio De Janeiro State University (uerj), Rio De Janeiro, Brésil

Context: Community Health Workers (CHWs) are key contributors to strengthening primary care and expanding access to preventative medicine. In Brazil, CHWs are central to the Family Health Strategy, delivering health education to communities, partaking in vaccination campaigns, and facilitating longitudinal patient follow-up. To understand the impact of CHWs on primary care worldwide, a synthesis of Brazilian and international findings is needed. Keywords: Community Health Workers; Preventive Medicine; Vaccination; Cancer Screening; Primary Health Care

Objectives: The primary objective of this work was to evaluate how CHWs influence: Vaccination coverage, cancer screening uptake and avoidable hospital admissions for chronic diseases. The secondary objective was to identify mechanisms through which community-based work increases engagement with primary care services.

Methods: An integrative review was conducted across PubMed, Scopus, and LILACS. Search terms included descriptors related to “Community Health Workers”, “Vaccination”, “Cancer Screening”, and “Preventive Medicine”. Filters applied: full-text availability, publications from the last 10 years, English or Portuguese. A total of 606 records were retrieved. After duplicate removal and

abstract/full-text screening, 29 studies were included.

Results: Of the 29 studies included, 17 reported increased vaccination rates associated with CHWs interventions. These workers acted as trusted sources of information—reducing vaccine hesitancy—and, in several contexts, served as vaccinators, reaching remote and vulnerable populations. 8 studies demonstrated improvements in cancer screening uptake linked to CHWs outreach and navigation. 5 studies highlighted reductions in avoidable hospitalisations and improvements in chronic disease management, reinforcing the role of CHWs in preventive care and early clinical intervention.

Discussion: CHWs improve preventive care by bringing people closer to the health system. In Brazil, many CHWs live in the same communities they serve, strengthening trust and helping them understand local needs. This proximity helps reach isolated or vulnerable groups and shows how community-based work can strengthen public health.

Conclusion: CHWs significantly improve preventive care outcomes by increasing vaccination and screening uptake, and reducing avoidable complications. Across international and Brazilian contexts, trust-building, relational continuity and local community ties emerges as key factors behind these improvements.

ID 580- Primary care dilemmas : How to diagnose diabetes types 1, 2 and everything in between

Arnila MELINA [(1)] , Mohd. Fikra Tri WIJAYA [(2)]

(1) University Of Muhammadiyah North Sumatra, Medan, Indonésie
(2) University Of Riau, Pekanbaru, Indonésie

Context: Wound care is a fundamental component of general practice and family medicine, particularly in low-resource settings where clinicians frequently manage chronic wounds, diabetic ulcers, burns, traumatic injuries, and post-operative complications. In countries such as Indonesia, the high cost and limited availability of advanced dressings create barriers to optimal wound care. This highlights the need for practical, affordable, and evidence-based alternatives. Honey, a traditional remedy with renewed scientific support, has demonstrated strong antimicrobial, anti-inflammatory, and tissue-regenerative effects, making it a suitable candidate for routine use in primary care wound management.

Methods: This practice-based reflection integrates clinical experience from Indonesian primary care settings (2024–2025) with evidence from peer-reviewed studies published between 2018 and 2025. Honey dressings were applied after cleansing with saline and covered with non-adherent gauze, with dressing changes every 24–48 hours. Honey was selected due to its accessibility, low cost, cultural acceptance. Strengths observed included accelerated healing, reduced infection rates, improved patient satisfaction, and suitability for home-based care. Limitations included variability in honey quality and limited availability of standardized medical-grade honey.

Originality: This experience provides a rarely reported perspective by showing how honey dressings are applied in real-world primary care and community settings. Unlike most studies centered on hospital wound units, this reflection highlights honey's practicality, low cost, cultural acceptance, and strong patient adherence in family medicine. It demonstrates its effectiveness for home-based care and offers a realistic, affordable model for wound management in resource-limited environments.

Lessons learned and future implications: Honey accelerated healing by 20–40%, reduced infection rates including MRSA, decreased treatment costs by up to 60%, and improved patient compliance due to ease of use and cultural familiarity.

Discussion: Honey's osmotic effect promotes autolytic debridement, while hydrogen peroxide production provides sustained antimicrobial activity. Anti-inflammatory properties reduce edema and pain, and its

bioactive components enhance granulation and epithelialization. These therapeutic properties, combined with affordability and accessibility, make honey highly compatible with primary care workflows.

Conclusion: Honey-based dressings are safe, accessible, economical, and clinically effective for primary care wound management. Their integration into routine family medicine practice can improve outcomes, reduce costs, and support holistic, patient-centered care in resource-limited settings.

ID 1066- Primary care remote consultation guidance across oecd countries: a scoping review

Elinor THOMAS [(1)] , Aleksandra TANAKA [(1)], Rebecca PAYNE [(2)]

(1) Cardiff University, Bangor, Royaume-Uni
(2) Bangor University, Bangor, Royaume-Uni

Context: Access to primary care in rural communities presents logistical and environmental challenges. Patients living far from healthcare facilities often rely on out-of-hours teleconsultations, but if medication such as antibiotics is needed, they may need to travel long distances to collect prescriptions. This creates barriers to timely care and contributes to avoidable travel-related carbon emissions. REMEDY project has introduced automated medication collection lockers and vending machines as alternative access points for urgently required out-of-hours medication. These systems may reduce travel and lower the environmental footprint of medication access. This study examines the carbon emissions associated with obtaining urgent medication after a tele-consult in rural Wales, comparing traditional hospital collection with the use of REMEDY lockers in Dolgellau/Holyhead.

Objectives: To quantify and compare carbon emissions associated with out-of-hours medication access following a tele-consultation via (1) hospital-based dispensing and (2) automated REMEDY collection lockers.

Methods: We will conduct a quantitative modelling study using retrospective data from patients who received an out-of-hours tele-consult resulting in urgent prescribing. The study population includes residents in rural areas served by the Dolgellau and Holyhead REMEDY systems who contacted the 111 service between December 2025 and May 2026. Home postcodes will be extracted from Adastra records. Travel distances for hospital collection versus the nearest locker will be calculated, and carbon emissions estimated using UK Government GHG Conversion Factors. Locker manufacturing emissions will be sourced from the supplier, and operational energy use measured via smart plug. These will be converted to per-use CO_2e values and added to total emissions estimates. The primary outcome is CO_2 emissions per medication access event.

Results: We anticipate lower travel distances, and therefore reduced CO_2 emissions, for patients using local REMEDY lockers compared with hospital collection. Locker operation emissions are expected to be minimal relative to travel savings, though final results will depend on usage patterns.

Discussion: Automated prescription lockers may reduce the environmental impact of medication access in rural communities while improving convenience and easing pressure on out-of-hours services.

Conclusion: By quantifying these effects, the study will provide evidence to support NHS Wales' decarbonisation strategy and guide wider adoption of innovations toward net-zero healthcare.

ID 1053- Primary Care Responses to Vaccine Refusal: Insights from a Qualitative Study Among Family Physicians

Dovydas TREPOKAS [(1)] , Eglė KIRIELIENĖ [(2)]

(1) Family Medicine, Lithuanian University Of Health Sciences, Kaunas, Lituanie
(2) Family Medicine Department, Šiaulių Rajono Savivaldybės Sveikatos Centras, Kuršėnai, Lituanie

Context: A patient with a two-year history of smoking and occupational exposure to metal dust with no chronic conditions experienced recurrent respiratory symptoms over ten months. This case illustrates the diagnostic and management challenges associated with recurrent bronchitis.

Methods: On 15 January 2025, the patient complained of fever (39.5 °C) and a cough that progressed from dry to productive, with greenish sputum. C-reactive protein (CRP) was 22.47 mg/L. Imaging revealed focal infiltrates in the right lung. A primary diagnosis of pneumonia was made, and a first course of Amoxiclav was prescribed. The patient's condition improved; however, cough and sputum persisted. Therefore, additional antibiotic therapy was initiated — Amoxiclav, Cefuroxime, Levofloxacin, and Clarithromycin — over the span of 9 months, despite normal chest X-ray, CBC, and CRP values below 10.2 mg/L, and negative tests for Chlamydia and Mycoplasma pneumoniae (performed nine months later). Pulmonology consultations concluded that the patient had acute bronchitis, most likely of viral origin. Spirometry results were normal, and sputum cultures were negative. Treatment with inhaled salbutamol and budesonide was prescribed, followed by physiotherapy and halotherapy. The patient's condition improved after antibiotics were discontinued at the beginning of October 2025.

Originality: This case describes the repeated use of antibiotics in a patient with bronchitis that was likely viral. It also highlights recent lifestyle changes, such as starting smoking and occupational exposure to metal dust, which may contribute to bronchitis but are often overlooked in routine clinical assessments.

Lessons learned and future implications: Early pathogen testing, referral to a specialist, combined with strict adherence to rational antibiotic prescription principles, could have avoided unnecessary antibiotic use. The patient's treatment should prioritize lifestyle changes, such as quitting smoking, changing the work environment, and, whenever possible, identifying the causative pathogen to reduce the risk of recurrence.

Discussion: Irrational antibiotic therapy contributes to antimicrobial resistance and may delay implementation of effective non-pharmacological treatments. Recognition of environmental exposures and lifestyle factors is crucial for targeted preventive strategies.

Conclusion: This case shows that recurrent bronchitis in at-risk individuals, such as smokers with occupational dust exposure, are often viral rather than bacterial. Early diagnostic testing and compliance with national antibiotic guidelines are key to avoiding unnecessary antibiotic use.

ID 2124- Primary membranous glomerulonephritis presenting with nephrotic syndrome in a young woman: a case report

María Isabel GUIRADO, Cynthia ANTEQUERA, Lorena MORALES

Servicio Andaluz De Salud, Almunecar

Context: 46 years-old patient, from Senegal, 10 years living in Spain. Consults for asthenia, nausea and epigastralgia for three months. Not high fever or infective symptoms.

Methods: Blood test with a bicytopenia. Anemia with Hemoglobine 4,1 and plaquets 52000.

Originality: We sent to the hospital for transfusion and further studies. Hematology took care of the patient suspecting a severnot autoimmunne severe hemolysis with non filiated cause.They ran a marrow bone biopsy with erythrocyte inclusions thath could also be parasitaries The patient escaped form hospital because he couldn't miss work

Lessons learned and future implications: We contact the patient, he went back to the hospital to finish studies, but rejected to stay there because of his personal situation. He still had some blood tests and an body-Scan to do. At the hospital he had the scan done, but we agreed to run the rest of the estudies in an outpatient manner.

Discussion: Some patients just cannot afford to be ill, their personal situation doesn't allowed, what to do them with those patient? We, family doctors, play a keyrole here, trying to keep in touch and trying to do a follow-up of the patient.

Conclusion: some people has difficult backgrounds, so we have to make sure we can help them the best we can not leave the patient behind and give thme the best attention according to their circumstancies.

(5) University Hospital Besancon, Besancon, France

Context: This workshop is designed for general practitioners navigating the increasingly complex landscape of respiratory virus immunisation in primary care settings. With multiple vaccines now available for influenza, COVID-19, and RSV, (and hMPV in the pipeline) each with distinct timing requirements, target populations, and administration guidelines, GPs face practical challenges in determining who should receive which vaccines and when.

Objectives: Update knowledge on current immunisation recommendations for acute respiratory viruses, including co-administration guidelines. Navigate special populations and contraindications.

Teaching method and workshop: Introduction (5 minutes) - Interactive poll & question Current Immunisation Landscape (15 minutes) - Key Respiratory Vaccines Priority Populations (15 minutes) - High Risk groups Practical Administration guidelines (10 minutes) - Co-administration - Timin

Expected outcomes: This workshop provides GPs with practical, evidence-based guidance to improve respiratory virus immunisation rates in their practice while building confidence in addressing patient concerns. Essential Resources: - National immunisation handbooks - WHO imm

Conclusion: Key Takeaway Messages: - Proactively identify and recall high-risk patients - Don't miss opportunities - vaccinate at any visit - Co-administration is safe and effective - Use presumptive communication strategies - Stay updated with national guidelines Action items: - Regularly audit your practice's immunisation rates and act on the results - Review your high-risk patient list - Update practice protocols - Train staff on vaccine communication

ID 540- Professional provider-customer interaction enhances their lives

María Isabel GUIRADO, Cynthia ANTEQUERA, Lorena MORALES

Servicio Andaluz De Salud, Almunecar, Espagne

Context: 71 years old german patient, living in our town for more than 15 years. He's not taken any medications and he has no clinical history. First time in the doctor in Spain. He has never smoked. He's having a headache that gets better with painkillers. As we talked and asked for any other sympthons in the patient, who has never been to the doctor before in our country, he tells us that he has been losing weight, about 8 kg in two months. He denies any urinary or digestive symptoms.

Methods: Blood test and X-ray results: An elevation in alfa1-alfa2-globulins, PCR and Ferritine levels with a decend of the global protein number, ferropenic anemia. Thoracic X-ray: showed an enlargement of the medistinic space. We asked for a Body-TC: Pulmonar mass that seemed neoplasic in LSD that affected the bronquial branches and also the pulmonary artery. Axilar and hiliar Lymphadenopathies Pulmonary, liver, occipital, hip and ribs metastases

Originality: The most difficult thing with this patient was the fact that he has been living a

normal life even when we gave him the diagnose and prognosis of his condition.

Lessons learned and future implications: The oncology service decided palliative radiotherapy and derivated the patient to paliative care unit. In our area, the palitive care unit is formed by a family doctor and nurse that covers a very large area, tha's why the follow-up and treatment of the pain and other symptons were done mostly by us, so we managed palliative symptoms and did the follow-up.

Discussion: The main key here is, how can we handle an apparently healthy patient that has never consulted before because he didn't have a condition that he knew about?

Conclusion: Sometimes the only thing we can do for aour patients is relieve thier symptoms

Corresponding author: María Isabel Guirado, guiradomaria.isabel@gmail.com

ID 1240- Profound Bilateral Hearing Loss in a Low-Risk Newborn: A Case Reflection from Primary Care

Swaleha TARIQ

Akuh, Karachi, Pakistan

Context: Sudden finger discoloration can raise concern for vascular, hematologic, or rheumatologic disorders. Achenbach's syndrome, a benign and self-limiting cause of acute digital ecchymosis, is often unfamiliar to clinicians—particularly in primary care.

Methods: Acute finger discoloration can be alarming and may suggest vascular, hematologic, or rheumatologic conditions. Achenbach's syndrome, a benign paroxysmal finger hematoma, is an uncommon but important diagnosis to recognize in primary care. We report a case of a middle-aged patient presenting with sudden purple discoloration of the right middle finger in a family medicine clinic. The case highlights evaluation, differential diagnosis, and management strategies relevant to primary care. Case Presentation A middle-aged woman presented with sudden onset of purple discoloration of the right middle finger, accompanied by mild pain. She denied trauma, cold exposure, or systemic symptoms. Examination revealed localized ecchymosis with normal pulses, capillary refill, and neurologic function. There were no other skin or nail changes. Considering the sudden discoloration, differential diagnoses included digital ischemia, Raynaud phenomenon, vasculitis, embolic events, traumatic hematoma, and coagulation disorders. Shared care with rheumatology was arranged to exclude systemic causes. Investigations were unremarkable, and the lesion resolved spontaneously within a few days.

Originality: It was the first time I had encounted such a patient, so sharing with other family physixcians will help in improving the quality care .

Lessons learned and future implications: I learnt a new differential diagnosis for discoloured finger and would apply that knowledge in future to improve patient care

Discussion: Achenbach's syndrome is characterized by sudden, painful, blue-purple discoloration of a finger due to spontaneous subcutaneous bleeding. It commonly affects middle-aged women and resolves spontaneously. Recognizing this benign condition in the family medicine setting is important to reassure patients, prevent unnecessary investigations, and reduce anxiety. Management is conservative, including rest, warm compresses, and analgesics. Shared care is warranted when systemic disease is suspected.

Conclusion: This case illustrates the role of family physicians in identifying benign digital hematomas. Awareness of Achenbach's syndrome enables timely reassurance, conservative management, and appropriate referral when necessary. Primary care clinicians can prevent over-investigation and provide effective patient-centered care for sudden finger discoloration.

(2) Primary Care Center Avenida De Aragón, Madrid, Espagne
(3) Primary Care Center Fronteras, Torrejón De Ardoz (c. Madrid), Espagne

Context: Acute neurological symptoms often present first in Primary Care, requiring decisions under uncertainty and with limited tools. This case illustrates how careful anamnesis and a focused neurological exam, coupled with an equity-driven referral strategy, enabled early management of a potentially severe central nervous system (CNS) condition.

Methods: A 24-year-old man attended Primary Care after waking with a sudden, severe headache, photophobia, nausea, myalgias, neck stiffness, and, critically, inability to move or feel both lower limbs (transient paresis). Focused examination confirmed inability to walk/stand and reduced lower limb strength. The constellation of red-flag symptoms suggested severe CNS pathology (e.g., meningitis, subarachnoid hemorrhage). Despite diagnostic uncertainty, the presence of danger signs prompted immediate and urgent referral to Emergency Services, prioritizing patient safety and equitable access to higher care. In hospital, neurological deficits partially normalized, but it was decided to perform a lumbar puncture. The results were decisive, showing lymphocytic pleocytosis. A diagnosis of acute lymphocytic meningitis was established.

Originality: The originality lies not in the final diagnosis, but in the process: managing a severe, yet transient, neurological deficit alongside meningeal signs in Primary Care. This case highlights that Primary Care's crucial role is detection (recognizing severity) over diagnosis, promoting a safety-first, equity-driven referral model often overlooked in the literature.

Lessons learned and future implications: The key lesson is that the most critical action was the timely recognition of danger signs and urgent referral, not diagnostic accuracy. Physicians must be cautious when severe, acute, and transient neurological signs appear. Future practice should reinforce training on recognizing low-incidence, high-risk constellations that mandate urgent referral. Post-discharge follow-up in Primary Care is essential for completing the etiological work-up (e.g., serologies, IGRA) while awaiting the neurology appointment.

Discussion: This case validates Primary Care's role as a critical filter in the health system. It demonstrates the superior value of clinical judgment and meticulous history-taking when advanced diagnostic tools are unavailable.

Conclusion: This case underscores Primary Care's responsibility to ensure rapid, fair access to emergency evaluation when red-flag symptoms arise. Accurate early detection was the key to achieving a safe clinical outcome, confirming Primary Care as the decisive gateway for managing time-sensitive CNS pathology.

Mellassine Maternal And Child Protection Center, Bechir Hamza Children's Hospital Of Tunis, Tunis, Tunisie

Context: Breast cancer is the most common malignancy among women worldwide and a leading cause of cancer-related death. Early detection in primary care improves outcomes,

highlighting the key role of frontline providers in screening.

Objectives: The aim of our study was to emphasize the pivotal role of primary care in breast cancer screening and to assess its impact on the early detection of breast malignancies.

Methods: We conducted a prospective interventional study involving 2,302 patients who presented to our institution over a three-year period, from October 2022 to October 2025. All patients who underwent breast imaging during this timeframe were included in the study.

Results: The average age of participants was 50 years (range 20–86), with a strong female predominance (9 males). Routine screening accounted for 65.7% of visits, while 34.3% presented with breast symptoms. All patients underwent clinical breast examination and structured interviews. Breast imaging (mammography ± ultrasound) was performed in 2,039 patients, including 1,632 with combined assessment. ACR classification showed mainly benign findings: 34.82% ACR1 and 39.64% ACR2. Probably benign lesions (ACR3) represented 19.05%, while suspicious lesions (ACR4 and ACR5) accounted for 5.47% and 0.68%, respectively. All male patients had bilateral gynecomastia. Core needle biopsy was indicated in 215 patients. Histopathology from 61 patients revealed invasive ductal carcinomas, 119 benign lesions, which were subsequently reassured.

Discussion: Our findings reinforce the strategic role of primary care in providing accessible breast cancer screening and enabling timely detection. However, experience from a regional investigation shows that limited patient awareness remains a major obstacle to adherence, highlighting the need for targeted educational initiatives. In our study, mammography proved effective in identifying suspicious lesions early, consistent with international evidence demonstrating up to a 63% reduction in mortality in settings with well-organized, high-quality screening programs. Global analyses from 2015 to 2021 also show greater declines in mortality in countries with regular, structured screening.

Conclusion: Primary care is pivotal to breast cancer screening owing to its accessibility and its crucial role in promoting awareness. Improved access to imaging is still needed to enhance early detection. Strengthening primary care involvement is therefore essential to optimizing screening efforts and reducing breast cancer mortality.

ID 531- Psychosocial Benefits of Cosmetic Procedures in Primary Care: A Systematic Review of Mental Health Outcomes

Nevena IVANOVA

Medical University Plovdiv Mhat Sveta Karidad Plovdic Burgas State University, Plovdiv, Bulgarie

Context: Cardiovascular disease remains a leading cause of preventable morbidity, particularly among vulnerable groups with limited access to preventive services. Real-world primary care settings often face barriers related to social, economic, and organizational factors. Vulnerable patients in this context include individuals with increased risk and restricted access to health services due to social, economic, or health-related factors.

Methods: This practice-based reflection is supported by a small quality improvement audit – an internal analysis of care quality within one urban general practice in Bulgaria, aiming at improvement. Twenty-eight patients with hypertension were followed over a three-month period (who/where/when). Interventions included shared decision-making, family involvement, proactive outreach, and simplified communication strategies (what/how/why). Educational activities with general practice residents reinforced humanistic and equitable care principles. Measurable outcomes were collected from routine clinical records. Strengths included direct applicability and real-world relevance; limitations involved small sample size, single-practice setting, and limited resources. Alternative approaches, such as digital engagement, were considered but not implemented due to feasibility constraints.

Originality: Patient and public involvement (PPI) in cardiovascular prevention appears rarely to have been implemented systematically in Bulgarian primary care, and published reports on PPI in this setting are limited. This experience demonstrates a novel application of PPI principles in a general practice context, integrating family engagement and resident training. Unlike most published PPI models, which are predominantly developed and implemented in hospital or research settings (tertiary care), this experience applies PPI principles in everyday real-world primary care practice.

Lessons learned and future implications: Engaging patients and families improved adherence and trust but required additional time and communication skills. Future practice could incorporate structured PPI tools and expand outreach to broader vulnerable groups. Caution is needed regarding sustainability and workload.

Discussion: This experience suggests that PPI can strengthen autonomy, equity, and humanistic relationships in everyday primary care while achieving measurable improvements in clinical engagement.

Conclusion: Implementing PPI in a real-world primary care setting improved follow-up attendance (58%→76%), medication adherence (62%), and screening uptake (+24%). This approach may support more equitable cardiovascular prevention among vulnerable populations.

ID 2021- Psychotic Depression Initially Presenting With Fatigue and Weakness in Primary Care: A Case Report

Anna BARAN, Robin OUSTLANDT, Jan BARAN

Mspu Corneille, Wattrelos, France

Context: Physical inactivity has become a major public health concern in the world due to its contribution to preventable morbidity. General practitioners (GPs) play a key role in promoting physical activity (PA), and evidence indicates that physically active GPs are more likely to counsel their patients on PA. Supporting GPs in improving their own PA levels may therefore strengthen preventive practices. However, little is known about the interventions designed to promote PA among GPs and about whether these interventions are evaluated.

Objectives: To identify interventions aimed at promoting physical activity among general practitioners and to assess whether their effects have been evaluated.

Methods: A systematic literature review was conducted following PRISMA recommendations. Eligible studies evaluated the effects of interventions promoting PA—directly or indirectly—among general practitioners. Only full-text articles were included. Two reviewers independently carried out study selection. Extracted data included study characteristics, intervention types, and outcomes. Methodological quality was assessed using the Medical Education Research Study Quality Instrument (MERSQI). A narrative synthesis was performed.

Results: Among the 3,375 references retrieved, five studies met inclusion criteria. Four were conducted in North America and one in Luxembourg. Interventions consisted either of structured training workshops targeting GPs or national PA promotion campaigns. Low to moderate quality evidence suggested that targeted interventions, particularly training workshops, were more likely to positively influence GPs' behaviour regarding PA counselling. No study assessed changes in the GPs' own physical activity levels, health status, or wellbeing. Evaluation methods and outcome measures varied widely, limiting comparability.

Discussion: The literature on interventions promoting PA among GPs is sparse and heterogeneous. Existing studies suggest a potential effect on counselling behaviours, but the absence of data on GPs' personal PA levels, and the low methodological quality of available studies, highlight important gaps. More robust evaluation strategies are needed, particularly those exploring behavioural, wellbeing, and organisational outcomes.

Conclusion: This review provides preliminary guidance for the development of a

participatory action research project currently underway within a Primary Care Territorial Community in XXX. The findings support the relevance of implementing a structured, targeted intervention and help inform the selection of appropriate evaluation criteria for future assessment.

ID 418- Qualitative study of medical reasoning in the management of patients of non-European origin

Eva María SANTIAGO SÁNCHEZ, María Lourdes MATEOS SÁNCHEZ, Evelin TRASTOY JIMENEZ, Ana CHUCHON ALVA, Estefanía Dolores GONZÁLEZ MARTIN

Primary Care, Ávila, Ávila, Espagne

Context: Subungual melanoma (SUM) is an uncommon form of cutaneous melanoma, accounting for approximately 0.7% to 3.5% of cases in the Caucasian population. This type of melanoma most frequently occurs on the thumb and the hallux. Its most common clinical presentation is the appearance of longitudinal melanonychia

Methods: A 65-year-old fair-skinned woman with no relevant medical history presented with a two-month history of longitudinal melanonychia on the right hallux. The lesion measured approximately 2 mm in width at its central portion and 3 mm at the base, and distal onycholysis was noted, together with an early Hutchinson's sign on the proximal nail fold. Given these findings, an urgent dermatology referral was requested, and a nail bed biopsy was performed. Histopathological examination confirmed acral lentiginous melanoma with a Breslow thickness of 0.7 mm. The patient is currently awaiting surgery for complete excision of the tumor with appropriate margins, and the tumor board is evaluating the need for a sentinel lymph node biopsy due to the aggressive nature of this histological subtype.

Originality: An unusual case due to the very early detection of a rare subungual melanoma, with an initial Hutchinson sign and low Breslow thickness. It differs from the literature because of its early presentation and the rapid coordination between primary care and dermatology.

Lessons learned and future implications: Early detection of suspicious melanonychia and prompt referral from primary care enable diagnosis of subungual melanoma at an early stage, improving the patient's prognosis.

Discussion: Subungual melanoma is an uncommon neoplasm with a poor prognosis, typically presenting as longitudinal melanonychia, sometimes accompanied by Hutchinson's sign. In this context, early recognition of these signs in primary care is crucial, as urgent referral enables earlier diagnosis and improves outcomes. As in our case, definitive diagnosis requires histopathological confirmation through a nail bed biopsy.

Conclusion: The treatment of melanoma depends on the stage of the disease and, in early phases, may range from local surgical excision to radical amputation of the phalanx. The staging workup includes imaging studies and sentinel lymph node biopsy, both essential for assessing potential local or distant spread. Keywords: Melanoma; Biopsy; Dermatology

ID 1814- Rapid primary-care screening for sleep apnoea with a chest-worn smartphone-based screening device and secure referral to sleep specialists

Anna BARAN, Ayed EIYA, Matthieu CALAFIORE, Isabelle CHARDONNET, Jan BARAN

Mspu Corneille, Wattrelos, France

Context: Traditional approaches to promoting physical activity (PA) often struggle to engage patients and healthcare teams in a lasting way. Yet creative, playful, or unexpected initiatives—sometimes involving the professionals themselves—can transform how PA is addressed in primary care. This workshop offers a participatory space where clinicians and health professionals can generate original, surprising, and feasible ideas to promote PA in their own settings.

Objectives: By the end of the workshop, participants will be able to: Generate unconventional and innovative strategies to promote PA among patients and healthcare professionals. Use simple creativity tools (brainwriting, creative constraints, rapid prototyping) applicable to primary care settings. Co-design, in small groups, a prototype of an innovative PA-promotion action tailored to their practice or local context. Identify key elements required to move from a creative idea to real-world implementation (stakeholders, resources, communication).

Teaching method and workshop: 10 minutes: Active icebreaker involving light movement and introdution. 10 minutes: Guided brainwriting using "What if…?" prompts. 20 minutes: Creativity cards introducing playful constraints (e.g., "no equipment," "in a waiting room," "with a patient c

Expected outcomes: Participants will leave with: -a set of innovative and practical ideas ready to be tested in their own practice or community; -a prototype of a PA-promotion action tailored to their context; -simple creativity tools they can reuse with colleagues; -renewe

Conclusion: This workshop will demonstrate that promoting physical activity in primary care can move beyond traditional counselling and become a creative, collective, and empowering process. By engaging participants in playful and imaginative problem-solving, it will encourage clinicians to rethink prevention, embrace innovation, and co-create actions that will resonate more effectively with patients and healthcare teams. The session will aim to spark new ideas, build confidence, and inspire participants to implement fresh, context-specific initiatives within their daily practice.

ID 254- Recognising Post-Artesunate Delayed Haemolysis

Philippe GUILLOU, Pierre MESSMER

Strasbourg University, Strasbourg, France

Context: In France, approximately 3,300 students enter general practice post-graduate program (residency) each year. They learn their future profession alongside university supervisors, who serve as role models—or counter-models. General practice residents seek supervisors with strong clinical reasoning skills, but the way they evaluate this reasoning remains unclear.

Objectives: To explore how general practice residents assess the clinical reasoning of their university supervisors, using a qualitative approach.

Methods: We conducted an interpretative phenomenological analysis of open-ended interviews, based on Pierre Vermersch's explicitation method. Participants were general practice residents from a faculty in the Grand Est region of France. Data collection took place from February to November 2024, with 9 interviews conducted until thematic saturation was reached.

Results: Participants identified five key criteria for evaluating their supervisors' clinical reasoning: Up-to-date medical knowledge and its application. Experience and ease of understanding clinical situations, alongside potential cognitive biases from routine. Organizational factors affecting clinical reasoning (e.g., time constraints, workload). Handling of uncertainty in decision-making. Emotional and pedagogical modeling in the supervisor-resident relationship. Residents appreciated supervisors' effortless comprehension of clinical situations but also noted cognitive biases and practice deviations from guidelines arising through experience . They valued open discussions about reasoning but feared negative reactions when challenging supervisors' views. Supervisors, in turn, sought residents' critical feedback to refine their practice.

Discussion: The hierarchical asymmetry in the supervisor-resident relationship may hinder constructive exchanges about clinical reasoning. Residents' observations highlight the need for mutual feedback to improve both teaching and practice.

Conclusion: Reducing hierarchical barriers could foster sincere, bidirectional discussions on clinical reasoning, benefiting both residents and supervisors. This approach may enhance the quality of general practice training.

ID 1374- Recurrent Herpes-Associated Erythema Multiforme: Diagnostic Challenges in Primary Care

Chia-Hsun LI, Yu-Ling HSU, Yu-Ting SU, Yi-Fen LI, Yu-Ling TSEN

Siansi Township Health Center, Changhua County, Taïwan

Context: Low-motivation smokers rarely seek cessation care despite higher risks for respiratory infections and reduced vaccine effectiveness. Every October, the government provides publicly funded influenza, COVID-19, and pneumococcal vaccines for high-risk groups. Using the Health Belief Model (HBM), we integrated vaccination visits with smoking cessation treatment to increase engagement.

Methods: The intervention was conducted in a rural public health center. Starting in October 2023, smoking history was assessed during vaccination visits using the standard vaccination evaluation form, reflecting a workflow change that integrated cessation screening into routine vaccination encounters. Smokers received counseling on the health effects of smoking and its impact on vaccine-induced immunity. Those who expressed willingness to quit were provided smoking cessation pharmacotherapy. The Wilcoxon signed-rank test was used to compare differences in smoking cessation treatment volume over the corresponding 30-week periods before and after the intervention.

Originality: Vaccination encounters can be opportunities for brief cessation interventions, yet evidence on integrating government-funded vaccination services with structured cessation treatment is limited. Our experience provides real-world evidence of feasibility in a rural setting.

Lessons learned and future implications: From October 2022 to April 2023, 268 cessation visits were recorded (mean 8.9/week). From October 2023 to April 2024, 463 visits were recorded (mean 15.4/week), a statistically significant 72.8% increase after the intervention. Integrating cessation into vaccination visits is feasible and effective, engaging smokers who may not seek care, especially in rural areas with limited access to cessation services. This model could be expanded across other public health vaccination programs. Future workflow improvements may include automated reminders within the vaccination evaluation system. Practical challenges included increased staff workload during peak vaccination periods.

Discussion: When individuals receive vaccinations in healthcare facilities, the concurrent inquiry about smoking history and provision of cessation advice correspond to the “cues to action” construct within the HBM. This approach may enhance other HBM constructs, including “perceived severity” and “perceived susceptibility” regarding smoking risks, as well as strengthen understanding of the “perceived benefits” of smoking cessation.

Conclusion: Integrating smoking cessation into vaccination visits significantly increased treatment utilization and engaged smokers who typically do not seek care. This HBM-based model is feasible, scalable, and promising for broader public health adoption.

ID 1813- Recurrent urinary tract infections in a pediatric patient: indications for further diagnostic evaluation in primary care

Xavier GOCKO, Pauline MATHOT, Catherine PLOTTON

Dmg Saint-Étienne, Saint-Étienne, France

Context: By 2025, lung cancer was the leading cause of cancer death worldwide. By 2021, only the USA, China and South Korea were offering organized screening for bronchopulmonary cancer using low-dose lung CT. In France, by 2025, a national research program is evaluating the criteria for organized screening (age, frequency, etc.). Participation in screening is based on a shared decision. The use of

decision-support tools promotes this process by reducing decision-making conflict.

Objectives: The main objective of this study was to describe the population included in screening, and the benefits and risks used in existing decision-support tools.

Methods: This review was recorded on Prospero. A systematic literature review was conducted according to PRISMA 2020 criteria by two researchers. The search was carried out on PubMed® and Google® (gray literature) between 2014 and 2024.

Results: Out of 700 articles identified, twenty decision-support tools were included. The majority came from the United States. Eligibility criteria for screening were mainly age between 55 and 80, smoker or former smoker of less than 15 years, with at least 30 pack years of smoking exposure. The quantitative benefit most used was: 3 deaths avoided out of 1000 people screened (18 versus 21) with annual screening for 3 years. The most frequently used limitation was the false-positive rate. The most common rate was 365 false positives per 1000 people after 3 years of screening, resulting in 25 invasive procedures, including 3 major complications.

Discussion: There was heterogeneity in the data presented in these tools in terms of benefits and risks. The presentation of a risk modifies its perception. Use of the Number Needed to Screen (304 in the NLST trial) was rare.

Conclusion: This review provides an overview of the different contents used in existing tools, which could serve as a basis for the development of a French tool.

ID 28- Red flags in back pain: early detection of multiple myeloma in primary care.

Chin Lin CHANG [(1)] , Yu Ting WEI [(2)], Yun Wen LI [(2)]

(1) Department of Occupational Medicine, China Medical University Hospital, Taichung, Taïwan
(2) Department of Family Medicine, China Medical University Hospital, Taichung, Taïwan

Context: Malignant pleural mesothelioma (MPM) is a rare, aggressive malignancy caused by asbestos exposure and often manifests decades after exposure. A 71-year-old retired shipyard worker first presented in 2022 with chronic cough and chest pain. His initial pleural effusion improved, but recurrence in 2024 prompted re-evaluation, raising concern for latent occupational disease.

Methods: Comprehensive imaging in 2024 revealed right-sided malignant pleural effusion, pleural nodules, and mediastinal lymphadenopathy, consistent with cT4 N0 M1a disease. Tumor markers were negative, and pleuroscopy confirmed epithelioid mesothelioma with no distant metastasis. The patient had worked 23 years in enclosed ship-hold spaces performing welding, sand-blasting, and painting with minimal respiratory protection, explaining his high-risk exposure. Strengths of management included persistent follow-up and timely recognition of occupational risk. A key limitation was intermittent surveillance between 2022 and 2024, potentially delaying earlier detection. All major diagnostic possibilities were considered, and confirmation through pathology provided clear clinical outcomes.

Originality: Unlike most mesothelioma reports emerging from tertiary oncology centers, this case originated in family medicine. It highlights how thorough occupational history at the primary-care level can lead to early suspicion despite nonspecific symptoms. The patient's 52-year latency and post-retirement diagnosis are longer than typically reported, emphasizing the need for lifelong vigilance. National post-employment health-surveillance subsidies further demonstrate how system-level support can enhance early occupational-disease detection.

Lessons learned and future implications: This case reinforces the need for routine exposure screening in patients with persistent respiratory complaints. Clinicians should exercise caution when symptoms recur after long asymptomatic intervals. Future practice can be improved by integrating structured occupational-history protocols and ensuring

regular follow-up for retired workers with known high-risk exposures.

Discussion: The case illustrates the diagnostic difficulty of MPM in primary care and shows how early recognition depends on linking subtle clinical findings with remote occupational exposures. Strengthening communication between primary care and surveillance programs can streamline earlier diagnosis.

Conclusion: This experience demonstrates the essential role of family medicine in identifying latent occupational malignancies and underscores the broader public-health impact of robust exposure-history assessment and post-retirement monitoring.

ID 1676- Redefining roles in primary care: evidence and tools for team transformation

Sarah MENESES [(1)] , Laëtitia GOSSELIN [(2)], Marie QUILLEY [(1)]

(1) Université Paris Cité, Département De Médecine Générale, Paris, France
(2) Université Paris Cité, Département De Médecine Générale ; Sorbonne Université, Inserm, Institut Pierre Louis D'épidémiologie Et De Santé Publique (iplesp), Paris, France

Context: Breastfeeding has proven health benefits for both mothers and children, as well as economic advantages. In France, 77% of mothers initiate breastfeeding after delivery, but the proportion declines rapidly within the first two months. After 10 weeks of paid postnatal leave, many mothers must balance their desire to breastfeed with their working lives. The use of electric breast pumps may help when returning to work, as well as in managing other challenges related to breastfeeding. Electric breast pumps are reimbursed when prescribed by a doctor or a midwife. In 2019, the prescription rules changed, shortening the initial prescription's duration for an electric breast pump.

Objectives: To describe trends in electric breast pump prescriptions between 2014 and 2024.

Methods: This epidemiological study is based on open data from the French health insurance system between 2014 and 2024. It includes comprehensive data on electric breast pump prescriptions, information on prescribers and users (region and age group), as well as reimbursement costs. These data were cross-referenced with demographic indicators on births, mothers, and medical density.

Results: This study shows an increase in reimbursements for electric breast pump rentals per child. Prescriptions by general practitioners rose rapidly after the 2019 change in prescribing rules accompanied by a decline in hospital prescriptions. There are significant regional disparities in the number of weekly rentals per child, with lower ratios in the Paris region and in overseas departments and regions. Despite an increase in the number of electric breast pumps rented and weeks of use, the overall cost has decreased since 2019.

Discussion: The transfer of hospital prescriptions to GPs, without any impact on midwives' prescriptions, highlights the growing role of GPs in promoting breastfeeding. Regions with more disadvantaged populations tend to use breast pumps less frequently, which is consistent with the literature, as socioeconomic disadvantage is described as a negative determinant of breastfeeding.

Conclusion: Electric breast pumps thus appear to be an increasingly common tool, both in mothers' habits and in medical practice, for promoting breastfeeding and prolonging its duration.

ID 1045- Red-Flag Headache Identified in Primary Care Leading to the Diagnosis of a Glomus Tumor: A Case Report

Lidia CARNIO, Raul Miguel ALLES, Lucia Helena Ludwig BRENTANO

Doctor, Porto Alegre, Brésil

Context: Acupuncture is an advanced technique promoting balance and self-regulation by acting on the spinal, brainstem, and diencephalic levels of the nervous

system.While integrated into Brazil's public health system since 2006, barriers remain. Limited availability of trained professionals and treatment spaces, combined with the standard requirement of eight sessions per patient, results in long waiting times that often extend from months to years.

Methods: To address this bottleneck, a group acupuncture approach was implemented, treating four women simultaneously in a shared space previously used for social activities rather than a standard clinical room. Patients lay on yoga mats while needling was performed, followed by two 20-minute stimulation rounds of different acupuncture points. This organization allowed for the completion of eight individual treatment equivalents within a single hour. The primary strength of this implementation was the significant reduction in time required compared to individual sessions, achieving measurable efficiency outcomes without compromising patient satisfaction.

Originality: This experience innovates by shifting the paradigm from the traditional one-on-one clinical model to a collective setting. Unlike standard literature which often focuses on individual efficacy, this case emphasizes logistical innovation: optimizing time and non-clinical space to increase throughput. The approach differs from standard care by reducing the total treatment time for four patients from four hours to just one, demonstrating a 75% reduction in time resource usage.

Lessons learned and future implications: A key lesson learned was that the group setting fostered a supportive environment; patients encouraged one another to attend subsequent sessions, thereby naturally reinforcing treatment adherence. Future implications suggest that this model is adaptable; based on the success over four months, there are immediate plans to extend this protocol to a male patient group.

Discussion: The results indicate that high patient satisfaction and therapeutic delivery can be maintained even when moving away from private, individual sessions. The simultaneous treatment model addresses the critical "supply and demand" disparity in public health by maximizing the utility of the practitioner's time.

Conclusion: By optimizing human and spatial resources, group acupuncture presents a viable, scalable solution to expand access and improve efficiency within public healthcare systems, effectively reducing waitlists while maintaining quality of care.

(2) Ganga Prem Hospice, Rishikesh, Inde
(3) Cambridge Global Health Partnerships, University Of Cambridge, Cambridge, Royaume-Uni
(4) Cancer Research Institute, Himalayan Institute Of Medical Sciences, Srhu, Dehradun, Inde

Context: This project highlights the importance of upskilling Allied Health Professionals (AHP’s) in two different countries (UK & India) to enhance community palliative care and reduce pressure on primary care teams. It is an international collaboration by a UK based global health partnership, aiming to improve the scope and utilisation of AHP roles within palliative care in India.

Methods: The abstract draws on preliminary observations from an August 2025 visit to the XXX hospice in India. The final reflection will incorporate findings from a more comprehensive dataset collected during a follow-up survey in February 2026. The outcome of the project is to design a structured training programme for Indian AHP’s visiting the UK in summer 2026. Key limitations include differing socio-cultural contexts and communication challenges. Indian data derive from a single site, while UK data represent national statistics.

Originality: No known studies have examined similar cross-cultural approaches to AHP development in palliative care.

Lessons learned and future implications: The UK team was struck by the central role families play in palliative care delivery in India, where healthcare workers empower family members and use existing social structures to deliver compassionate care. Care in the Indian setting was noted to be more sustainable and resource-efficient. Both teams recognised that national policy and funding structures profoundly shape hospice care. The Indian team gained awareness of early referral pathways for end-of-life patients and the benefits of early palliative intervention for people with non-malignant disease.

Discussion: Preliminary findings emphasise the value of international collaboration in shaping more holistic, sustainable, and culturally sensitive models of palliative care. AHP involvement in Indian palliative care remains at an early stage. Observations from both teams highlighted key similarities and differences in practice. Findings from the February 2026 visit are expected to identify opportunities for mutual learning and inform development of a targeted blended training programme to strengthen AHP capacity.

Conclusion: This project demonstrates that equitable global partnerships enable two-way learning, regardless of socio-economic contexts. Cross-cultural understanding facilitates interprofessional fraternity and shared purpose among healthcare workers working in a community palliative care. Future initiatives will strengthen this collaboration

through continued empowerment of AHP's to deliver high quality end-of-life care.

ID 1869- Regarding a case of HIV in adolescence: Aspects in which Primary Care contributes

Eunsu CHUNG

Seoul National University Hospital, Seoul, Corée (République de)

Context: Obesity is an established risk factor for severe influenza and is classified as a high-risk condition by national and global health authorities. However, previous studies show inconsistent evidence on whether obese individuals are more likely to receive influenza vaccination in Korea. With substantial shifts in vaccination policies and population behavior surrounding the COVID-19 pandemic, updated evidence is needed.

Objectives: To investigate whether obesity shows independent association with influenza vaccination among Korean adults, and to assess whether this association varies by survey year or sex.

Methods: We analyzed national representative data from KNHANES 2019–2023. Adults aged ≥20 years with available BMI and vaccination data were included. Obesity was categorized according to Korean BMI criteria: normal (<25.0 kg/m²), stage I (25.0–29.9 kg/m²), and stage II+ obesity (≥30.0 kg/m²). Vaccination status was self-reported as yes or no. Survey-weighted logistic regression assessed associations adjusting for age, sex, education, income, and region. Additional analyses included sex-stratification and year-specific models.

Results: A total of 16,242 adults from 2019-2021, and 10,560 from 2022-2023 were analyzed. Higher BMI groups showed slightly higher vaccination rates (e.g., 2019: normal 41.1% vs. stage I+ 44.0%, 2022: normal 40.0% vs. stage I+ 44.8%), but differences were not statistically significant. In adjusted models, none of the obesity stages showed significant association across the entire period. Most year-specific analyses also displayed no significant association before or after COVID-19. However, in 2022, individuals with stage I+ obesity showed significantly higher odds of vaccination (OR 1.14, 95% CI 1.02–1.27), but this association did not persist when divided into more detailed BMI stages.

Discussion: Obesity did not independently predict influenza vaccination. Demographic and socioeconomic factors such as age, sex, and income were stronger determinants. The temporary increase in 2022 may reflect heightened risk perception and public-health messaging during the early post-pandemic period.

Conclusion: Obesity does not appear to be a major determinant of vaccination among Korean adults. Improving vaccination coverage may require addressing socioeconomic and demographic barriers rather than focusing solely on weight status. Further research is required to identify subgroups within the obese population who may benefit from targeted vaccination strategies.

(2) Antimicrobial Materials Lab., Dynesoze Co., Ltd., R&d Center, Yongin, Corée (République de)

Context: Functional dyspepsia (FD) is characterized by one or more symptoms, including epigastric pain, burning, early satiety, and postprandial fullness, occurring in the absence of identifiable structural abnormalities on imaging or endoscopy. Symptomatic improvement with pharmacological treatment is often unsatisfactory due to the heterogeneous nature of the condition.

Objectives: This study evaluated the efficacy of a green tea seed and leaf extract complex (TSL) in alleviating symptoms of FD.

Methods: Eligible participants were adults aged 19–70 years who presented with at least one of the four FD symptoms defined by the ROME IV criteria and showed no structural abnormalities on upper gastrointestinal endoscopy. In a double-blind, randomized, placebo-controlled trial, 100 adults with FD were assigned to receive either TSL (n = 50) or placebo (n = 50) at a dose of 500 mg/day for 8 weeks.

Results: The primary endpoint was the change in total score on the Gastrointestinal Symptom Rating Scale (GSRS). The TSL group demonstrated a significantly greater improvement in total score compared with the placebo group (-5.73 ± 6.27 vs. -2.02 ± 7.09, P = 0.0148). Analysis of changes in individual GSRS symptom scores revealed that, at the 8-week follow-up, reflux (−1.02 ± 1.27, P < 0.0001) and abdominal pain (−1.12 ± 2.14, P = 0.0017) significantly decreased in the TSL group compared with baseline. No significant differences were observed between groups in the incidence of severe adverse events (AEs), and all AEs were deemed unrelated to the study materials.

Discussion: Previous research has indicated that catechins found in green tea leaves, particularly epigallocatechin-3-gallate (EGCG), exert anti-inflammatory and antioxidant effects by interacting with cell membrane receptors, modulating intracellular signaling pathways, and influencing nuclear transcription regulators. Collectively, these findings suggest that the improvement in FD symptoms observed in the present study may be attributed to the multiple anti-inflammatory mechanisms of green tea.

Conclusion: In conclusion, various gastrointestinal symptoms improved after 8 weeks of administration of 500 mg TSL in adults with FD, without severe AEs. Our findings indicate that TSL may be an effective and safe alternative for managing symptoms in adults with FD.

Context: Due to its portability and accessibility, point-of-care ultrasound (POCUS) has significant potential for application in primary care settings. POCUS offers a portable, radiation-free imaging modality that can support timely clinical decision-making.

Objectives: To review current evidence on the use of POCUS in community and home care settings, and to evaluate its applications, benefits, and limitations relevant to primary care practice.

Methods: A comprehensive literature search was conducted across six databases in April 2024. Studies involving the use of POCUS in home or community settings for diagnostic purposes, monitoring, procedures, or clinical management were included. A total of seven studies and five case series or reports met inclusion criteria.

Results: POCUS was applied across diverse community settings by physicians, nurses, and specialists. Key uses included screening and diagnosis of deep vein thrombosis, heart failure, ascites, pleural effusion, pneumonia, and intra-abdominal pathology. POCUS supported clinical decisions such as fluid assessment, dyspnoea evaluation, urinary retention assessment, and medication titration. It also facilitated bedside procedures including paracentesis and nasogastric tube placement, with high reported sensitivity and specificity. Emerging evidence showed promising roles for artificial intelligence (AI) integration, enabling accurate assessments by operators with limited training.

Discussion: Findings demonstrate that POCUS enhances accessibility to diagnostic imaging in community settings, improves triage, and supports real-time decision-making for patients with limited mobility. It enables safe

delivery of bedside procedures and may reduce unnecessary hospital visits. However, operator dependency remains a key challenge, necessitating structured training, competency assessments, and clear clinical frameworks to prevent overdiagnosis. AI integration shows promise in reducing variability and supporting less experienced users, but further validation is needed before large-scale implementation.

Conclusion: POCUS is a powerful tool with numerous potential applications in community and home care settings. Current literature highlights only a fraction of its capabilities, with many applications still underexplored. There is considerable potential for future research to expand the use of POCUS in home care, as well as to develop training programs for its application and integrate AI to enhance diagnostic support.

ID 989- Relationship between cardiovascular risk and daily step counts for community health workers in a family health center

Yang LUO, Hong Hwee LIM, Munirah SALAUDDIN, Chong LEE SZE, Esther VERGHESE, Bee Choo LEE, Tan DIHAO KEITH, Lim ZILIANG

Nhg Health, Singapore, Singapour

Context: Influenza infection is associated with considerable morbidity and mortality among individuals aged 65 and above. Influenza vaccination has been shown to significantly reduce complications in this vulnerable group, leading to annual vaccination recommendations from various authorities, including the Centers for Disease Control and Prevention.

Objectives: In alignment with the World Health Organization's target of a 75% influenza vaccination coverage rate, this audit project aims to enhance influenza vaccination uptake among a cohort of elderly patients managed under the "Teamlet Care Model" in a Singapore polyclinic.

Methods: A root-cause analysis was conducted to identify key factors contributing to the low vaccination rate. A multi-voting was carried out to identify top causes, which include limited emphasis on influenza vaccination among doctors and nurses, high cognitive load on healthcare staff during consultations, and limited patient awareness of vaccination benefits.

Results: Targeted interventions were implemented, using the Plan-Do-Study-Act (PDSA) cycle as a model for improvement. Initial intervention include a continuing medical education (CME) session on vaccination importance, messaging prompts via Microsoft Teams, and visual cues strategically placed in workspaces to serve as reminders. Staff feedback has indicated an increase in vaccination offers to the target population as a result of these interventions. The uptake of influenza vaccination increased from a baseline of 33.28% (median = 726) to 36.57% (median = 876) over a period of 6 months. The influenza vaccination rate continued to increase post-intervention to date (February 2025), to 36.94% (median = 886).

Discussion: The pre- and post-intervention analysis revealed that the intervention led to an increase of 117 vaccinated elderly patients. A local study that reported 36 million cost savings per 100,000 patients over a 10-year period. Estimated annual cost savings projected would be SGD 4,212 for the current project.

Conclusion: To maximize impact, interventions can be expanded clinic-wide to benefit a larger patient population. Regular talks can be carried out to reinforce the importance of influenza vaccination among doctors. Pop-up reminders for target patients can be integrated to the electrical medical records system to further enhance recall. To further enhance sustainability, a quick-response code can replace brochures to reduce paper waste and minimize manpower for distribution.

(1) Queen Mary University Of London, London, Royaume-Uni
(2) Sangam Surgery, London, Royaume-Uni

Context: Back pain is one of the most common presentations in primary care. Distinguishing benign musculoskeletal causes from serious pathology presents a huge diagnostic challenge. This can be compounded by language barriers. This case demonstrates how GPs can use the tools at their disposal, namely the visual analogue scale (VAS), strong clinical suspicion, and critical analysis of inconsistent findings, to diagnose the most obscure of cases.

Methods: A 58-year-old man presented to the GP with non-specific lower back pain. The consultation was complicated by a language barrier, with the son translating, limiting the reliability of the history. The neurological and spinal examination was normal; however, blood tests revealed normocytic anaemia and an isolated elevated ALP. Despite a normal lumbar X-ray, the patient reported disproportionate pain reflected by his high VAS score. This inconsistency, combined with the anaemia, triggered the GP's clinical curiosity, who referred the patient via a 2-week haematological malignancy pathway. The MRI revealed extensive spinal metastases secondary to stage IV prostate cancer. It was due to the GP's clinical suspicion, combined with his critical analysis of non-specific investigations, that led to this diagnosis.

Originality: Although prostate cancer is well documented, very rarely does it present solely as back pain, without urinary, neurological or red flag symptoms. The uniqueness of this case lies in how the initial imaging appeared normal. Nonetheless, the diagnostic pathway was instead spearheaded by clinical intuition, biochemical abnormalities, and a mismatch between symptoms and objective findings. Few cases highlight the value of VAS scoring in discriminating malignant differentials or the impact of language barriers in masking underlying pathology.

Lessons learned and future implications: This case underscores the importance of early interpreter involvement to prevent diagnostic blind spots. It reinforces that a clinician's mind, along with baseline blood tests, is a powerful diagnostic tool. GPs should always remain curious, especially when imaging and symptoms do not align. In the future, artificial intelligence in imaging can be utilised to minimise diagnostic errors and identify subtle metastases.

Conclusion: This case illustrates the crucial role of GPs' clinical suspicion and holistic assessment in identifying serious diseases hidden within routine presentations.

Vilija OKE, Carina SANNESTEN, Eva WALDHEIM, Aleksandra ANTOVIC

Rheumatology Unit, Dept Of Medicine, Karolinska Institutet, Stockholm, Suède

Context: Psoriatic arthritis (PsA) is a diverse disease by manifestations, but also timing of cutaneous and musculoskeletal symptoms onset. Timely recognition of disease symptoms in primary care and referal to specialists is of importance in order to manage disease and associated comorbidities.

Objectives: To investigate whether the order of symptom onset associate with distinct clinical profiles of PsA.

Methods: PsA patients were randomly invited to participate in the study at routine visit. The study investigated 121 patients who recalled and reported order of symptom onset. Data on subjective and objective variables were analysed across the identified subgroups: those whose symptoms started with psoriasis (PF, 53.7%), arthritis (AF, 26.5%) or simultaneously both (S, 19.8%).

Results: In the PF subgroup, age at onset of musculoskeletal symptoms correlated negatively with time to PsA diagnosis (r=-0.44, p<0.001) and these patients had the most prominent dyslipidaemia. The S subgroup had the shortest time to diagnosis and a higher proportion of patients had less active PsA disease, and also a healthier lipid profile. Higher proportion of AF subgroup had higher disease activity at inclusion, were overweight (50%) or obese (35.5%), and waited the longest time to PSO diagnosis. Temporomandibular joint involvement was observed in 20.7% and axial PsA in 17.5%, with similar frequencies across the subgroups. Overall, 25.5% reported sexual problems, with the lowest frequency in the PF subgroup (16.5%). Depression was as common across the subgroups (19.6%).

Discussion: The study demonstrates that order of symptom onset in PsA is associated with different PsA profiles: the S group had shortest waiting time to diagnosis, healthier lipid profile and higher proportion of patients had low active disease, and suggest that timely diagnosis might provide better outcomes. The PF subgroup waited longest time for PsA diagnosis, in particular those who developed MSK symptoms at younger age; PF had most pro-atherogenic lipid profile and delayed treatment could be contributing factor. AF patients had high disease activity at inclusion, but also highest incidence of overweight or obesity, and could benefit of both inflammation and weight reducing therapies.

Conclusion: Altogether we demonstrate that order of symptom onset reveal distinct PsA profiles and early diagnose is of importance.

ID 992- Research workshop on multi-professional consensus methods

Laura JOVELL, Bibiana GALÍ, Daniel ALCANTARILLA

Cap Santa Clara, Girona, Espagne

Context: Hypervitaminosis B12 is discussed far less frequently than vitamin B12 deficiency, despite being more common as well as clinically significant, remaining underdiagnosed and underestimated in routine practise. Its origin may arise from a broad spectrum of causes, ranging from benign excessive supplementation to serving as a marker of underlying pathology, including solid tumours, hematologic malignancies and hepatic or renal dysfunction. Despite these potential implications, most health centres lack standardized protocols for assessment and management of hypervitaminosis B12.

Methods: A 40-year-old female presented elevated levels of vitamin B12 (1299 pg/mL) in a routinary laboratory evaluation with her primary care physician. The patient reported no accompanying symptoms, including fatigue, neuropathic manifestations or cognitive changes. No significant past medical history was reported, including malignancy, toxic substances or alcohol consumption, smoking history, known liver/kidney disease or autoimmune disease. No supplements intake was reported. Known allergies: pyrazolones. Medication: atorvastatin, paracetamol. IUD wearer. Physical examination revealed no clinically significant findings. Laboratory studies revealed persistently elevated serum vitamin B12 (1407 pg/mL) when re-tested 8 weeks later. The diagnostic work-up revealed no abnormalities in the other laboratory parameters, with the complete blood count within normal limits, normal liver enzyme levels and preserved renal function. A recent CT scan a couple months prior showed no significant alterations, only a non-obstructive 3mm lithiasis in the right kidney was observed. Once all probable secondary causes were ruled out, the hypervitaminosis B12 was considered idiopathic. Further laboratory assessments can be carried out to monitor these persistently elevated B12 values.

Originality: Hypervitaminosis B12 is discussed far less frequently than vitamin B12 deficiency, despite being clinically significant, and remaining underdiagnosed and underestimated in routine practise.

Lessons learned and future implications: Primary care physicians are often the first to encounter abnormal vitamin B12 results. Recognizing elevated B12 levels as a potential marker of serious underlying pathology is essential.

Discussion: Persistently high levels of B12 warrant a comprehensive workup to rule out analytical interference and identify potentially occult diseases, particularly malignancies or organ dysfunction. A thorough evaluation can facilitate earlier detection and management, thereby improving patient outcomes.

Conclusion: Primary care providers play a pivotal role in the early recognition and evaluation of hypervitaminosis B12.

Nzoz Im. L. Rydygiera, Olsztyn, Pologne

Context: In our work, we try to present the economic and organizational aspects of conducting rehabilitation within the structure of a rural primary health care clinic.

Methods: Based on own experience, conclusions and economic and administrative analysis of the functioning of a small rehabilitation unit at primary health care.

Originality: The rural clinic in Jonkowo was the first primary healthcare facility in Poland to introduce rehabilitation into its organizational structure 20 years ago. Our team has helped introduce similar innovations in several other rural centers, with varying degrees of success. We are happy to share our experiences.

Lessons learned and future implications: Presentation of the structure and organization of the physiotherapy workshop at primary health care and the economic basis of the project.

Discussion: Is rehabilitation at a family doctor's office necessary? What funding is needed? How should the team be organized?

Conclusion: Rehabilitation at rural primary healthcare facilities is highly recommended and necessary. External financial regulations do not always produce the expected results.People from rural areas have the same right to rehabilitation as city dwellers. This is due to simple economic reasons, such as the payment of similar health insurance premiums. Due to the specific nature of rural living, the risk of injury is greater, and living outside the city, with its numerous architectural barriers, requires greater physical fitness.

Context: After the outbreak of war in Ukraine, millions of refugees sought medical help and social support from our country. We obtained permission from the Ethics Committee to conduct sensitive research.

Methods: To gather information, we created a survey in Ukrainian for refugees—our patients. We analyzed the collected data.

Originality: No one had previously conducted such research based on a survey and individual patient perceptions.

Lessons learned and future implications: The aim of our study is to compare healthcare systems in Ukraine and Poland while also addressing social issues to better understand the needs and expectations of Ukrainian and others immigrants affected by the war.

Discussion: Can any instructive conclusions be drawn from comparing different healthcare systems?

Conclusion: The war in Ukraine is an aggressive conflict raging in Europe, claiming enormous casualties among the warring parties. From the very first days of fighting, our 2 small clinics has been actively involved in providing medical assistance to refugees from Ukraine. We hired

staff with language skills and provided information about treatment options at our facility. By November 2025, we had provided approximately 9,800 consultations. Helping war victims was and remains our primary value. We also asked patients dozens of questions. We included a small portion of the answers in our presented work.

ID 1999- Resiliency in Care: A Family Medicine Case of Adult Autism Spectrum Disorder in a Rural Community

Raj THAKKAR, Meredith DONALDSON

Primary Care Cardiovascular Society, High Wycombe, Royaume-Uni

Context: Statin monotherapy does not enable most patients with established atherosclerotic cardiovascular disease (ASCVD) to achieve the 2025 ESC lipid targets.1 Inclisiran is reimbursed for use in primary care in England for patients with ASCVD and an LDL-C ≥2.6mmol/l.2 Despite its strong evidence base, favourable safety profile, and national reimbursement scheme, reluctance to initiate inclisiran persists among some UK healthcare professionals (HCPs).

Objectives: To identify barriers to inclisiran use among UK HCPs

Methods: A cross-sectional lipid-based electronic survey was conducted between September and October 2025 on HCPs from the Primary Care Cardiovascular Society (UK) membership database. One of the questions explored barriers to using lipid-lowering therapies beyond statins.

Results: 69 HCPs responded to the questionnaire: 28 (41%) were GPs (including GPs with a special interest in CVD or trainee GPs), 20 pharmacists, 16 nurses, and 5 other HCP types. 3 HCPs used statins alone – 2 citing the local medical committee (LMC) as a barrier to prescribing other medicines. Of the 40 who didn't use inclisiran, several barriers were cited, including lack of outcome data (n=6, 15%), cost (n=7, 17.5%), unfamiliarity (n=12, 30%) and advice from the local medical committee (LMC, n=17, 43%).

Discussion: LMC advice, followed by unfamiliarity with inclisiran, appear to be the most influential barriers to its adoption in UK primary care.

Conclusion: Targeted education and peer support may increase clinician familiarity, confidence and uptake of inclisiran. Given the substantial impact of LMC guidance on prescribing behaviour, careful consideration by influential organisations must be taken to avoid unintentionally limiting patient access to guideline-directed lipid-lowering therapies.

ID 441- Retrospective study of Cardiac Amyloidosis (AC), Red Flags, Cardiorenal syndrome [Chronic Kidney Disease (MRC)-Heart Failure (HF), and BUN/creatinine ratio (UCR).

Raj THAKKAR

Primary Care Cardiovascular Society, High Wycombe, Royaume-Uni

Context: The coding of Long Term Conditions (LTCs) in primary care electronic records is central to a robust registration, recall and review system. In addition, failure to flag important diagnoses can lead to a coding inequality gap and potential harm due to a) failure to recall and optimise individuals b) failure to communicate patients' diagnoses in correspondence c) prescription of medicines that may cause potential harm. It is known that there is a coding deficit in a number of LTCs including hypertension and atrial fibrillation.(1)

Objectives: It was hypothesised that there was a significant under-coding in heart failure (HF) across GP systems. This programme aimed to review healthcare records with a view to understanding the quantum of the coding deficit and ultimately make recommendations to avoid coding deficits in the future.

Methods: A programme of work, named "Excellence in Heart Failure", was initiated with an Academic Health Science Network (AHSN, now called Health Innovation Network), and one of the southern counties in England. The project was underpinned by several strands

including a desktop review and clinical coding in hitherto un-coded patients with HF, and face to face optimisation of select patients with guideline directed therapies. Patients with potential HF were identified from electronic record searches on specific drug therapies and/or echocardiogram reports.

Results: The project ran for a year (2020/21).152 patients were added to the HF register (increasing the HF prevalence by 15%). 319 patients had specific code adjustments with the addition of a HFrEF (LVSD at the time of the project) code leading to more accurate care records. 151 patients received medication optimisation changes.

Discussion: A significant number of individuals with HF did not have a problem code in their primary care electronic record. This may have potentially lead to patients being lost to follow-up or sub-optimally treated.

Conclusion: Desktop reviews can identify individuals with HF who are otherwise uncoded and potentially undertreated. Under-coding can lead to an inequality gap and risk patients being lost to follow-up. It is essential that disease registers are maintained to deliver robust recall and review systems, and to reduce risk to patients.

Context: Point-of-Care Ultrasound (POCUS) is reshaping family medicine, enabling rapid

bedside diagnosis for cardiovascular, respiratory, abdominal, and musculoskeletal conditions. Building on the successful Pilot Leonardo 3 EURACT project, supported by WONCA Europe and WESIG POCUS, this workshop adapts the ABC Clinical Ultrasound curriculum for a pan-European audience. The initiative was experimented with in a pilot project that has already engaged over 110 expert trainers, who have conducted 4 European workshops with more than 250 participants, demonstrating feasibility and high interest across multiple countries. The program combines evidence-based theoretical training with hands-on practice, fostering standardized, competency-based POCUS education across diverse primary care settings.

Objectives: Learning objectives: Showcase the ABC Clinical Ultrasound curriculum and its European adaptation. Demonstrate practical POCUS applications in everyday family practice with Real Time Demonstration. Explore strategies for building sustainable trainer networks across Europe. Facilitate interactive discussion and shared learning among participants.

Teaching method and workshop: ▶Teaching methods: Interactive presentation of the curriculum and its European implementation Case-based discussions illustrating real-world POCUS use Video demonstrations and practical tips for hands-on skill development Group brainstorming on scaling PO

Expected outcomes: Participants gain actionable strategies for integrating POCUS into primary care. Standardized curriculum and trainer network approaches are shared to support sustainable skill dissemination. Enhanced collaboration across European WESIG POCUS members, prom

Conclusion: This workshop equips family physicians and trainers with practical tools, hands-on techniques, and a networked European framework for POCUS implementation. By combining curriculum innovation, case-based learning, and collaborative discussion, participants will be empowered to improve patient care, strengthen primary care diagnostics, and contribute to a continent-wide culture of evidence-based ultrasound education.

ID 949- Rheumatoid Arthritis Follow-Up in Primary Care: Identifying Potential Barriers to Reduce Morbidity

Paola HILLIARD

Sorbonne Université, Paris, France

Context: Touch is a sense that is omnipresent in healthcare relationships and can be difficult to understand. The intimate nature of this contact requires a thoughtful approach and could benefit from specific training. Dance, with its defined framework and sensitive approach to the body, could serve as a space for exploring touch.

Objectives: Explore the experience of touch among general practitioners who practice dance.

Methods: Interpretative phenomenological qualitative study. Semi-structured individual interviews were conducted with general practitioners who practice dance. The analysis allowed superordinate themes to emerge after triangulation.

Results: The nine interviews revealed that touch, marked by an evolving relationship with consent, whilst on the one hand made the care relationship more empathetic, was also not easy to approach for participants. Thus, dance allowed them to explore the intention behind touch, improve their empathy, and add complexity and nuance to the experience of touch by modulating the semantics surrounding it. The absence of critical reflection when training to become a doctor made it difficult to become aware of one's actions. The development of critical thinking was linked to chance encounters and could be encouraged by research work.

Discussion: The practice of dance could serve as a place to explore this relationship with touch through a process of modulation that nuances the experience of touch by introducing new imaginaries. The compartmentalisation of

professional and private life makes it difficult for general practitioners to transpose any experiences between these two worlds. One explanation for this phenomenon could be the loss of cross-disciplinary skills among doctors, linked to the rise of scientific medicine, which has led to over-specialisation among healthcare professionals.

Conclusion: The experience of touch is constantly evolving throughout a caregiver's career, leaving neither the person touched nor the toucher indifferent. Its perception is marked by current societal changes, prompting doctors to take the patient's experience into account. Dance could serve as a place to explore this relationship to touch. To encourage doctors and medical student to question their relation to touch, the development of research and the introduction of collectively guided reflection time on the possible exchanges between dance and touch could be useful levers.

ID 320- Rhinitis Right Care: improving diagnosis and management in primary care.

Joana BAPTISTA ALVES, Liliana BARBOSA, Maria FORTUNAS TEIXEIRA, Sara RIBEIRO

Usf Vimaranes, Uls Alto Ave, Guimarães, Portugal

Context: Hemorrhagic stroke commonly presents with acute focal neurological deficits, but atypical or subtle manifestations may delay diagnosis.

Methods: An 80-year-old man with a history of coronary artery bypass graft, chronic liver disease, hypertension, type 2 diabetes and dyslipidemia, presented with an eight-day history of exertional low back pain and numbness in the left leg. He denied other symptoms. Physical and neurological examination were unremarkable except for mild left lower limb sensory deficit (tactile and vibratory). The clinical presentation led the physician to request cranial and lumbar CT and schedule a re-evaluation one week later. The patient was admitted to the emergency room two days later, after referral by the radiologist who reviewed the cranial CT. It revealed a recent right lenticulocapsular and insular hemorrhage with mild perilesional edema, without ventricular rupture or midline shift. He was admitted for monitoring and secondary prevention, with initiation of physiotherapy and outpatient neurorehabilitation. The patient remained neurologically stable, with persistent mild hypoesthesia but no new deficits at discharge after three days. Three weeks later, he was re-evaluated by the family physician. Family support was assessed and fall-prevention strategies were reinforced alongside other preventive measures, including strict blood pressure control and continuation of motor and cognitive rehabilitation.

Originality: This case highlights the importance of maintaining a high index of suspicion for cerebrovascular events, particularly in elderly patients with subtle neurological symptoms, although the acute phase of such pathologies is less expected in primary care. This case also emphasizes the longitudinal role of the family physician in diagnosis, monitoring, and rehabilitation coordination.

Lessons learned and future implications: Family physicians play a crucial role in ongoing care, integrating medical, functional, and psychosocial interventions, reinforcing preventive strategies, and supporting rehabilitation. Future practice should maintain vigilance for subtle neurological deficits and strengthen multidisciplinary follow-up pathways.

Discussion: This case demonstrates that subtle neurological symptoms in elderly patients may indicate acute cerebrovascular pathology. Primary care physicians are pivotal in ensuring timely diagnosis and orchestrating comprehensive long-term care.

Conclusion: Longitudinal involvement of the family physician—from initial suspicion to post-acute rehabilitation—is essential for accurate differential diagnosis and person-centered care, enhancing recovery and autonomy in elderly patients.

Corresponding author: Joana Baptista Alves, 8228@ulsaave.min-saude.pt

ID 241- Right Retrobulbar Optic Neuritis in a 52-Year-Old Woman Living With HIV: Diagnostic Challenges and Early Therapeutic Response

Arij MARZOUGUI

Faculty Of Medicine Of Tunis, Tunis, Tunisie

Context: Female obesity is a growing public health concern worldwide, including in XXX , and represents a major contributor to infertility. Its impact on ovulatory function, hormonal balance, and assisted reproductive technology (ART) outcomes is well established. Given the central role of primary care in early infertility evaluation, lifestyle counselling, and obesity management, synthesizing existing evidence is essential for guiding clinical practice.

Objectives: To synthesize XXX and international evidence on the impact of female obesity on fertility and to identify effective interventions that improve reproductive outcomes.

Methods: A narrative review was conducted following a structured search strategy. Literature published between 2010 and 2025 was identified through PubMed, Google Scholar, and EM-Consulte. Eligible sources included observational studies, systematic reviews, meta-analyses, and professional society guidelines. Studies focusing on XXX populations were specifically highlighted. Inclusion criteria were adult women with obesity and outcomes related to ovulation, polycystic ovary syndrome (PCOS), or ART success. Exclusion criteria included male-factor infertility and studies lacking reproductive outcomes. Data were synthesized narratively according to themes : ovulatory function, PCOS prevalence, and ART outcomes.

Results: Across international evidence, obesity is consistently associated with ovulatory disorders, increased prevalence of PCOS, and reduced success rates of ART procedures such as in vitro fertilization (IVF) and intracytoplasmic sperm injection (ICSI). Lifestyle interventions—particularly moderate weight loss and regular physical activity—improve ovulatory function and pregnancy rates. XXX studies similarly report a high prevalence of obesity among infertile women, frequently associated with PCOS and chronic anovulation.

Discussion: The findings highlight the multifactorial impact of obesity on female fertility and reinforce the need to address both metabolic and reproductive aspects in clinical care. In XXX , where obesity prevalence among women is high, integrating culturally adapted lifestyle interventions into primary care could significantly improve reproductive outcomes.

Conclusion: Female obesity remains a significant contributor to infertility. Strengthening multidisciplinary management—including lifestyle-focused primary care interventions—and improving coordination with reproductive specialists are crucial for optimizing fertility outcomes. Future research should evaluate the effectiveness of locally adapted interventions and their impact on long-term ART success.

ID 277- Risk Factors and Frequency of Vitamin B12 Deficiency among Patients Visiting Primary Care Clinics in Karachi, Pakistan

Paolo Augusto ROMERO MERINO, Rosa María GONZÁLEZ LÓPEZ, Carmen DE SANTIAGO GONZÁLEZ, Ayeiza Maria FELIPE LEPES, Carlos Eduardo GOMES RODRIGUES CORREIA

Centro De Salud Arrabal De Portillo, Valladolid, Espagne

Context: Complications of community-acquired pneumonia (CAP) such as empyema are uncommon but carry high morbidity in older adults,particularly those with frailty,prior airway surgery,and cognitive impairment.Primary care often faces the challenge of differentiating mild infections from early signs of severe disease.This case reflects how subtle clinical changes detected in primary care can lead to early referral and appropriate escalation of diagnostic imaging and multidisciplinary assessment.

Methods: A 79-year-old man,laryngectomized for epidermoid carcinoma,with hypothyroidism,dyslipidemia,esophageal

stenosis,prior cholecystectomy complicated by abscess,and mixed dementia,presented in primary care with 5 days of increasing tracheal secretions,fatigue,and functional decline.Examination revealed mild tachypnea,right basal hypoventilation,and disorientation.A portable chest X-ray demonstrated a right pleural effusion,prompting urgent referral to hospital.POCUS showed a 30 mm anechoic pleural collection with internal debris and compression of adjacent parenchyma. Laboratory tests suggested inflammatory activation.CT of the thorax revealed right lower lobe consolidation with air bronchogram, a pleural hydroaerial level compatible with empyema,and bilateral emphysema with areas of ground-glass opacity.Bronchoscopy-guided thoracic ultrasound confirmed a cavitated lesion, and thoracentesis yielded scant serohematic fluid.Due to the small loculated chamber and the patient's frailty, immediate drainage was deferred.

Originality: This case is notable for the combination of a cavitated empyema in a laryngectomized,cognitively impaired older adult,initially presenting with nonspecific symptoms easily attributed to baseline status.It highlights how POCUS in primary care and early imaging escalation can change the diagnostic trajectory.Similar reports in the literature usually describe clearer infectious presentations,whereas in this case deterioration was subtle and identified only through attentive longitudinal assessment.

Lessons learned and future implications: Primary care is essential in detecting early respiratory decline,especially in frail patients with altered baseline examinations.Diagnostic coordination between primary and hospital care,including the increasing use of bedside ultrasound,may prevent delays and reduce complications.

Discussion: The case underscores the complexity of decision-making regarding drainage in empyema when frailty and procedural risk complicate management.Multidisciplinary evaluation allowed individualized care while avoiding unnecessary interventions.For family physicians,the case reinforces the importance of functional change,caregiver reports,and maintaining high suspicion in vulnerable populations.

Conclusion: Early identification of deterioration in primary care and coordinated escalation of diagnostic testing enabled timely recognition of a cavitated empyema,improving patient safety and demonstrating the fundamental role of primary care in managing complex respiratory infections.

ID 1549- Rôle de l'hémoglobine glyquée (HbA1c) dans la prédiction du risque cardiovasculaire chez les patients diabétiques de type 2 : étude descriptive à visée analytique

Darinka PUNOSEVAC, Milena KOSTIC, Maja VUCKOVIC

Section Of General Medicine, Serbian Medical Society, Belgrade, Serbie

Context: As GPs (general physicians) we often criticize our patients about their diet, body weight, and lifestyle. But do we follow our own advice?

Objectives: We aimed to determine the overall health of GPs in Southeast Europe and assess their adherence to medical advice they give.

Methods: We conducted an anonymous online survey among our colleagues in Serbia and the surrounding region from July 15 to July 31, 2024. The study was quantitative, and we utilized descriptive statistics to analyze the data.

Results: We received 788 responses, with 82.6% of the respondents being women and almost 60% of the participants falling into the 41-60 age range. For their mental wellbeing, most GPs often turn to their families (85.3%) and hobbies (67.1%). The majority consider their diet moderately healthy (73.2%), with 14.8% considering it very healthy. A normal BMI (18.5-24.9 kg/m2) is found in 54.5% of the participants. Over 50% of the respondents do not exercise at all or merely once a week.

Additionally, almost 80% do not consume alcohol or smoke cigarettes. The majority of the participants (76%) are married or living with their partner. More than half of the respondents are willing to accept lower pay if it means achieving better work-life balance.

Discussion: In a similar research conducted in the USA 2024, family physicians indicated that they primarily relied on their families for maintaining mental health balance (80%). A significant percentage turned to exercise (66%) and therapists (10%). Similarly to our research, 53% of the participants aimed to reduce their current body weight. The percentage of those who do not exercise was lower (30%) than in our research. A study conducted in the USA and Canada in 2009 revealed that family physicians who lead healthy lifestyles are more likely to influence their patients to change their bad habits, serving as better role models. Patients view general practitioners who discuss their own habits as more credible and motivating.

Conclusion: GPs have different habits related to healthy lifestyles. Their personal experience and example may be helpful to patients in adopting healthy lifestyles and thus preventing the onset of chronic diseases.

ID 1502- Role of Emotional Intelligence & Leadership Skills in General Practice

Nathanja VAN MOPPES [(1)], Bahar GOLCHEHR [(2)]

(1) Amsterdam Umc, Amsterdam, Pays-Bas
(2) Radboud Umc, Nijmegen, Pays-Bas

Context: Inclusive medical education is essential for attracting, supporting, and retaining diverse trainees, thereby reinforcing sustainable and patient-centered healthcare systems. Evidence shows that patients feel better understood and adhere more effectively to treatment when physicians recognize social, cultural, and personal dimensions of care. Such awareness fosters trust, enhances self-management, and improves efficiency and quality across healthcare delivery. Nevertheless, trainees from underrepresented backgrounds in Dutch GP-specialty training continue to encounter inequitable learning opportunities, limiting individual development and the healthcare system's ability to deliver equitable, future-ready care. In response, Amsterdam UMC GP-specialty training institute has developed and piloted research-informed interventions for inclusive medical education, now being scaled nationally with support from two Diversity, Equity, and Inclusion (DEI) Coordinators. Embedding DEI-leadership within training programs empowers educators as drivers of structural change, linking inclusive learning environments to sustainable, high-quality care—a pioneering development within European medical education.

Objectives: This workshop invites GPs, GP-trainees, GP-educators and mentors, and GP-educational developers to explore evidence-informed approaches to strengthening inclusive education, share practical experiences in addressing leaky pipelines through which GP workforces lose essential diverse talent, and build networks that support ongoing (inter)national collaboration. Participants will recognize challenges and opportunities in inclusive medical education, gain insight into initiatives that promote diversity, equity, and inclusion, acquire practical tools and visual frameworks connecting inclusive learning to future-ready care, and establish a collaborative network for continued innovation.

Teaching method and workshop: The workshop offers interactive, collaborative learning strategies, including visual mapping, dialogue-based reflection, peer-to-peer exchange, and structured networking. 0–5 min: Introduction to theoretical frameworks, objectives, and relevance for heal

Expected outcomes: Participants will gain enhanced insight and practical tools for promoting inclusive GP-specialty training, along with international networks for continued exchange.

Conclusion: By integrating research, exchange, and networking, this workshop advances inclusive GP-specialty training and thereby, contributes to a sustainable, diverse, and future-ready GP workforce.

ID 228- Screening for violence and access to health care: study of experiences of violence and attendance at general medical appointments

Joana BAPTISTA ALVES, Liliana BARBOSA, Maria FORTUNAS TEIXEIRA, Sara RIBEIRO

Usf Vimaranes, Uls Alto Ave, Guimarães, Portugal

Context: Multiprofessional collaboration within Family Health Units (FHU) is essential for the early identification of postoperative complications. Cerebrospinal fluid (CSF) fistula is an important postoperative complication after lumbar spine surgery due to the risk of rapid progression to central nervous system infection (CNS).

Methods: We report a 50-year-old male patient, previously submitted to two L5–S1 discectomy and decompression. Due to recurrence of the disc herniation with poorly controlled lumbosciatic pain, he underwent new surgery in 2025. One week postoperatively, the patient attended the nursing consultation for wound care at the FHU. He reported severe orthostatic headaches with cervical irradiation, experiencing a syncopal episode while entering the office. The nurse conducted an initial assessment and promptly requested evaluation by a Family Medicine physician. Based on clinical assessment, a CSF fistula was suspected, prompting urgent referral to the Emergency Department. The diagnosis was confirmed, and the patient required two reoperations. His six weeks stay was complicated by CNS infection, L5–S1 motor and sensory deficit, urinary retention and neurogenic constipation. The patient currently presents residual L5–S1 right-sided hypoesthesia and neurogenic bladder dysfunction managed with scheduled intermittent catheterization, while continuing physiotherapy.

Originality: Although CSF fistula following lumbar surgery is well described, early recognition in primary care settings is rarely reported. This case differs from existing literature by highlighting the decisive role of FHU-based multiprofessional teamwork in identifying a complication that is typically diagnosed in hospital contexts.

Lessons learned and future implications: This case underscores the need for high clinical suspicion when evaluating recent postoperative patients presenting with nonspecific symptoms. It also reinforces the importance of structured communication pathways within FHUs, which may be further optimized to accelerate decision-making and referral.

Discussion: Early recognition of this potentially severe condition was facilitated by effective communication and collaboration between nursing and medical staff. The case demonstrates how coordinated primary care follow-up contributes to patient safety in the postoperative period.

Conclusion: Close collaboration between nurses and physicians in the FHU was pivotal for early diagnosis of a CSF fistula. The case emphasizes that, although Family Medicine may appear as an individual practice, that high-quality, safe care in Family Medicine depends on cohesive multiprofessional teamwork.

ID 1263- Screening Models in Primary Care for Marginalised Groups

Maria Lourdes MATEOS SANCHEZ, Evelin TRASTOY JIMENEZ, Ana María CHUCHON ALVA, Estefania Dolores GONZALEZ MARTIN, Eva Maria SANTIAGO SANCHEZ

Primary Care, Avila, Avila, Espagne

Context: A 71-year-old woman with a history of obscure gastrointestinal bleeding developed sudden epigastric pain followed by multiple episodes of coffee-ground vomiting, hematochezia, and a syncopal episode at home. Prehospital emergency services found her pale and hypotensive (85/55 mmHg) and initiated early management with IV access, crystalloid infusion and intravenous omeprazole, achieving initial hemodynamic stabilization. The rapid identification of a probable mid-gut hemorrhage and timely prehospital treatment allowed safe transfer for further evaluation.

Methods: Clinical data were collected through direct prehospital assessment, emergency department evaluation, and review of electronic medical records. Hemodynamic parameters, laboratory values, and imaging findings were analyzed to characterize the severity and progression of the gastrointestinal bleeding. Management followed local emergency protocols for hemorrhagic shock and gastrointestinal bleeding, integrating prehospital stabilization, early pharmacologic therapy, and multidisciplinary communication.

Originality: This case is original because it highlights the crucial role of primary care and prehospital emergency teams in identifying and stabilizing an uncommon but severe mid-gut arterial bleed. The rapid recognition of hemodynamic compromise at home, combined with early activation of diagnostic pathways and coordination with referral centers in a rural setting lacking interventional Radiology.

Lessons learned and future implications: Mid-gut bleeding is an infrequent but potentially life-threatening cause of acute gastrointestinal hemorrhage. Early recognition in primary and prehospital care is crucial to avoid delays in diagnosis and transfer to specialized centers, particularly in settings without local interventional radiology.

Discussion: This case highlights the diagnostic challenge of mid-gut bleeding and the essential role of prehospital evaluation in hemodynamic stabilization and early suspicion of distal small-bowel hemorrhage. Rapid collaboration among primary care emergency teams, radiology, gastroenterology, and intensive care enabled timely transfer despite the absence of on-site interventional radiology.

Conclusion: Early recognition and coordinated management of active mid-gut bleeding in the prehospital and emergency setting can significantly reduce delays to definitive care and improve patient outcomes, particularly in rural or resource-limited areas.

ID 1134- Seeing the Unseen - Intellectual Disability in Primary Care: How to Recognize, Report, and Respond

Vitória CRUZ, Bárbara ALVARENGA, Pedro PEREIRA, Mário José GOMES, Maria João SÁ

Usf Faria Guimarães, Porto, Portugal

Context: Abnormal uterine bleeding (AUB) is a common gynecological complaint in primary care and significantly affects women's quality of life. Its heterogeneous etiologies make initial assessment challenging, and appropriate early evaluation is crucial for guiding management and referral decisions. Developing a clear, evidence-based protocol can support clinicians in standardizing initial care.

Objectives: To develop an evidence-based protocol for the initial assessment and management of AUB in non-pregnant women in the primary care setting.

Methods: A narrative review was conducted using UpToDate, narrative and systematic reviews, clinical practice guidelines, and consensus statements published by recognized professional organizations in the last ten years. Sources addressing the evaluation and management of AUB in non-pregnant women were included. Literature focusing exclusively on pregnant patients or highly specialized interventions was excluded. Findings were synthesized to construct a practical and clinically applicable protocol. The synthesis emphasized diagnostic sequence, red-flag identification, and use of the FIGO PALM-COEIN classification system.

Results: The review supports a structured, stepwise approach to AUB in primary care. Initial evaluation requires assessment of hemodynamic stability, promptly identifying acute cases requiring urgent intervention. In stable patients, pregnancy must be excluded using a pregnancy test. A positive result warrants referral to obstetrics. If pregnancy is excluded, clinical assessment should proceed with a detailed history, focused physical examination, and targeted diagnostic testing guided by clinical suspicion. The PALM-COEIN framework provides a standardized method to categorize structural (PALM) and non-structural

(COEIN) causes. Management options vary according to etiology, ranging from watchful waiting and medical therapy to referral for gynecological evaluation when specialized investigation or treatment is required.

Discussion: The findings highlight the importance of a systematic, evidence-based approach in primary care to improve diagnostic accuracy, avoid unnecessary delays, and ensure appropriate use of specialist services. Incorporating standardized classification tools such as PALM-COEIN enhances consistency in assessment and communication across care levels.

Conclusion: The proposed protocol offers a clear, evidence-informed pathway for the initial evaluation of AUB in non-pregnant women in primary care, supporting timely diagnosis and appropriate referral. Its implementation may improve clinical decision-making and patient outcomes and provides a foundation for future research on protocol effectiveness in real-world practice.

ID 2090- Seeing what was already there: A reflection on chronic pain, context, and clinical integration

Ponlawat NIKHOMKHAM, Kulnida MUKHJANG, Watcharasak PHONGPRAPAI

Department Of Family Medicine, Sawanpracharak Hospital, Nakhonsawan, Thaïlande

Context: Benign Prostatic Hyperplasia (BPH) is a primary cause of Lower Urinary Tract Symptoms (LUTS), adversely affecting the quality of life in elderly men. While patients with Metabolic Syndrome (MetS) frequently present with LUTS, evidence regarding the association between MetS and LUTS remains unclear.

Objectives: To analyze the association of MetS with the severity of LUTS and Quality of Life (QoL) in male patients with chronic diseases.

Methods: This prospective observational cross-sectional study was conducted at the Primary Care Unit of Sawanpracharak Hospital in 2025. The study population consisted of males aged 50 years and older who attended the Non-Communicable Disease (NCD) clinic with complete metabolic profiles. LUTS data were collected using the International Prostate Symptom Score (IPSS). The association between MetS and LUTS was analyzed using multivariable ordinal logistic regression.

Results: A total of 91 male patients were included: 58 with MetS and 32 without. In the MetS group, 34.5% exhibited moderate and 5.2% severe symptoms. No significant association was found between MetS and LUTS severity (Adjusted OR = 1.28; 95% CI: 0.34 – 4.84) or urinary-related QoL (Adjusted OR = 1.47; 95% CI: 0.46 – 4.69). However, within the MetS group, patients with moderate symptoms showed a significant association with dissatisfaction in QoL (Adjusted OR = 6.44; 95% CI: 1.35 – 30.68; p = 0.019).

Discussion: Although MetS is not directly associated with LUTS severity, its presence significantly impacts QoL in patients with moderate symptoms, suggesting that patients with metabolic comorbidities may possess a lower tolerance for urinary tract abnormalities compared to the general population.

Conclusion: Metabolic Syndrome is not associated with LUTS severity but significantly impacts QoL in patients presenting with moderate symptoms or higher. Consequently, NCD care in primary care settings should incorporate LUTS assessment to ensure holistic management and improved quality of life for patients. Keywords: Metabolic syndrome, Benign Prostatic Hyperplasia, Lower Urinary Tract Symptoms

(3) General Practitioner, Lyon, France

Context: Osteoarthritis affects 65% of the French population over the age of 65. Osteoarthritis is a painful condition and results

in reduced physical function and quality of life, and increased risk of all cause mortality

Objectives: This study evaluates the efficacy of oral codeine, with or without paracetamol and/or NSAIDs, in the treatment of arthritic pain.

Methods: Included studies assessed codeine efficacy for arthritic pain in adults at all stages, excluding spinal pain. Risk of bias was analyzed using the RoB2 method. The primary outcome was pain reduction. Meta-analyses were conducted with Revman 5.4.1, and evidence levels were assessed using REB and GRADE methods.

Results: Six RCTs, with one showing low risk of bias, were included, enrolling 621 patients. The meta-analysis showed evidence of a beneficial effect of codein on arthrosis (SMD = -0.64 [-1.11; -0.17]) over 32 hours to 4 weeks. However, REB and GRADE methods concluded "lack of evidence" and "very low evidence," respectively. Secondary analyses showed limited efficacy for codeine combined with paracetamol or ibuprofen. Codeine's efficacy over 32 hours was classified as a signal requiring confirmation

Discussion: There is no strong evidence to support codeine's use for peripheral osteoarthritis pain beyond 32 hours of treatment. Secondary analyses didn't find efficacy for combinations with paracetamol or ibuprofen. Adverse effects further weaken the benefit-risk ratio. This review underscores the need for robust RCTs to evaluate codeine's role in osteoarthritis management This is the first systematic evaluation of the efficacy of codeine in the treatment of osteoarthritis. More high-quality studies with minimal bias are needed to strengthen and refine current evidence.

Conclusion: Prescribing codeine is not recommended for osteoarthritis according to current scientific knowledge.

Centro De Salud Arrabal De Portillo, Valladolid, Espagne

Context: Type 1 diabetes mellitus (T1DM) typically appears during childhood or adolescence, yet autoimmune diabetes in adults is increasingly recognized. Its presentation may be subtle and overlap clinically with type 2 diabetes, creating diagnostic uncertainty in primary care. Early identification of autoimmune etiology is crucial to avoid delays in insulin initiation and prevent metabolic decompensation. This case illustrates the role of primary care in recognizing atypical presentations and guiding timely referral.

Methods: A 30-year-old man with no significant past medical history attended a routine occupational medical examination where an incidental hyperglycemia (334 mg/dL) was detected. He reported several weeks of dry mouth and polydipsia, without polyphagia, weight loss or polyuria. He denied alcohol or tobacco use and had a family history of diabetes in a paternal uncle. He presented to the emergency department, where capillary glucose was elevated and simple ketosis was confirmed. Insulin therapy with Lantus 12 units nightly was initiated, achieving metabolic stabilization. Physical examination revealed a BMI of 26.5 kg/m², normal vital signs, appropriate hydration, and no signs of infection or acute illness. Laboratory tests showed normal renal function and electrolytes. Autoimmune markers performed subsequently demonstrated positivity for anti-GAD antibodies, confirming the autoimmune origin. During follow-up, the patient required basal-bolus therapy with rapid-acting insulin titrated to 3–4–4 units per meals. HbA1c at three months was 6.0%, with fewer than one weekly hypoglycemia episode. Education on carbohydrate counting and self-adjustment of insulin doses was provided.

Originality: Adult-onset autoimmune diabetes remains underdiagnosed and is often mistaken for type 2 diabetes, delaying appropriate treatment. This case highlights an atypical presentation without ketoacidosis or significant symptoms despite severe hyperglycemia.

Lessons learned and future implications: Incidental hyperglycemia, even in asymptomatic adults, requires structured evaluation including autoimmune markers. Early insulin therapy prevents progression to ketoacidosis and reduces long-term complications

Discussion: Family physicians often encounter ambiguous hyperglycemia. Understanding latent autoimmune diabetes in adults facilitates earlier referral, personalized treatment and prevention of misclassification.

Conclusion: Adult-onset T1DM should be considered in lean, asymptomatic adults presenting with unexplained hyperglycemia. Comprehensive assessment and coordinated care between primary and specialized services optimize outcomes.

Centro De Salud Arrabal De Portillo, Valladolid, Espagne

Context: Superior mesenteric artery syndrome (SMAS) is a rare cause of duodenal obstruction resulting from narrowing of the aortomesenteric angle.Its symptoms are non-specific and often overlap with functional gastrointestinal disorders frequently assessed in primary care.Because progressive weight loss may aggravate the anatomical compression,SMAS can lead to a self-perpetuating cycle of malnutrition.This case illustrates the essential role of primary care in recognizing warning signs,coordinating investigations,and supporting long-term management.

Methods: A 38-year-old woman was referred for nutritional evaluation due to progressive weight loss over one year. Her habitual weight was 54 kg; recent measurements showed 47.6 kg and BMI 16.8 kg/m².She reported early satiety, postprandial abdominal discomfort,and subjective muscle loss,with no vomiting or alarming gastrointestinal symptoms.Physical examination revealed reduced muscle mass,minimal physical activity,and stable vital signs.Laboratory studies showed no evidence of malabsorption or inflammatory disease.Duodenal biopsies demonstrated preserved villous architecture, excluding celiac disease.A contrast-enhanced CT scan revealed gastric dilation with a markedly reduced aortomesenteric distance (4 mm) and an aortomesenteric angle of 12°, consistent with SMAS.Additional findings included dilation of the left ovarian vein and periuterine varicosities,suggestive of pelvic congestion syndrome. Other abdominal organs were unremarkable.The patient was diagnosed with severe malnutrition secondary to SMAS.Nutritional therapy was initiated with high-calorie oral supplements and small frequent meals. Vascular surgery evaluated potential interventions, including stenting of the superior mesenteric artery or alternative endovascular options.Follow-up assessments monitored weight,symptom progression,and functional status.

Originality: SMAS is uncommon, particularly in young adults without prior surgical history. Its overlap with benign gastrointestinal complaints often leads to delayed recognition.The coexistence of venous pelvic congestion added further complexity to the diagnostic process.

Lessons learned and future implications: Persistent weight loss and early satiety should prompt early imaging when initial evaluations are inconclusive.Primary care plays a pivotal role in detecting nutritional decline, coordinating multidisciplinary communication,and ensuring timely referral.

Discussion: This case highlights the importance of continuity in family medicine for monitoring subtle but progressive symptoms.Early identification of SMAS may prevent severe malnutrition and reduce the need for invasive interventions.

Conclusion: SMAS should be considered in patients with unexplained weight loss and postprandial discomfort. Timely diagnosis and

coordinated care are essential to improve outcomes and restore nutritional status.

Centro De Salud Arrabal De Portillo, Valladolid, Espagne

Context: Ulceronecrotic tonsillitis is an uncommon and potentially severe form of acute tonsillar infection. Its presentation may raise concern for deep neck infections or hematologic disorders, making early recognition and adequate follow-up essential. This case highlights the role of primary care in initial assessment, risk stratification, and coordination with specialized services to prevent complications.

Methods: A young adult presented to primary care with a three-day history of odynophagia unresponsive to oral amoxicillin initiated at home. She reported dysphagia but no dyspnea, fever, or systemic symptoms. Her medical history was unremarkable except for a previous episode of tonsillitis. Examination revealed hypertrophic tonsils with ulceronecrotic appearance, more pronounced on the left side, without uvular deviation or signs of peritonsillar abscess. Cervical lymphadenopathy was present but non-fluctuant.The patient was clinically stable and afebrile.Given the atypical findings, she was referred to otorhinolaryngology for urgent evaluation.During hospital observation, she remained hemodynamically stable and tolerated oral intake. Repeat examination showed bilateral pharyngeal improvement and reduction of ulceronecrotic plaques. Analytical tests demonstrated leukocytosis and decreasing C-reactive protein (from 175 mg/L to 53 mg/L). No signs of airway compromise or deep neck infection emerged. She was discharged with amoxicillin-clavulanic acid every eight hours for seven days, a tapering course of oral prednisone, and paracetamol as needed. She was advised to return to emergency care if fever, worsening dysphagia, respiratory difficulty, or cervical swelling appeared. Follow-up with ENT was arranged for six to eight weeks.

Originality: Ulceronecrotic tonsillitis is rarely encountered in routine primary care.Its presentation mimics more serious conditions such as Lemierre's syndrome,agranulocytosis, or necrotizing infections, underscoring the need for accurate early evaluation.

Lessons learned and future implications: This case reinforces the importance of identifying red-flag symptoms and recognizing atypical patterns of tonsillitis.Clear communication and expedited referral pathways allow efficient exclusion of severe causes and avoid unnecessary antibiotic escalation.

Discussion: From a primary care perspective,this case illustrates the value of comprehensive examination, safety-netting, and shared management with ENT specialists.Early referral prevented diagnostic uncertainty and ensured appropriate monitoring until clinical resolution.

Conclusion: Ulceronecrotic tonsillitis, though rare, should be considered in patients with persistent odynophagia and atypical tonsillar findings.Timely evaluation and coordinated care enable safe outpatient management and prevent complications.

Patricia MENDOZA [(1)] , Mel Anthony ACUAVERA [(2)]

(1) The Medical City, Las Pinas City, Philippines
(2) The Medical City, Manila City, Philippines

Context: Universal Health Coverage is central to ensuring equitable access to healthcare without financial hardship. Despite regional progress, Southeast Asian countries show disparities in UHC performance due to varying economic capacities and health system readiness. This study aimed to assess the Philippines' UHC status relative to its Southeast

Asian neighbors; and analyzing their relationships with economic indicators.

Objectives: To evaluate UHC in the Philippines and other Southeast Asian nations - To compare UHCSCI scores in the Philippines and other Southeast Asian nations - To assess the economic status and examine it alongside UHCSCI scores

Methods: This cross-sectional ecological study utilized WHO and World Bank data from eleven Southeast Asian countries. Descriptive and correlational analyses examined patterns between UHCSCI scores and economic parameters.

Results: Among UHCSCI scores, the Philippines fell within a middle-tier performance among other countries, performing excellently in antenatal care but lagging in multiple sub-indices. The GDP PPP per capita showed logarithmic relationships with UHCSCI, suggesting diminishing returns in UHC beyond US$20,000. Conversely, health expenditure showed an inverse relationship with UHCSCI, suggesting efficiency, not total spending, drives better outcomes.

Discussion: Performance varied across Southeast Asia, with the Philippines' UHCSCI score falling midrange of regional performance. Areas of improvement include disease management, and having adequate health workforce. Analyses implied that economic growth contributes to better health coverage up to a certain threshold. Data also highlights that higher spending alone does not guarantee better outcomes, showing inverse relationship between health expenditure and UHCSCI. Instead, high-income countries demonstrated that efficient governance, resource distribution, and primary care systems drive improvements in service coverage, underscoring need for efficiency, accountability, and performance-based allocation.

Conclusion: For the Philippines, these patterns emphasize the need to strengthen its healthcare system's foundations. Lessons from high-performing countries suggest that integrating preventive care and having locally applicable interventions can improve efficiency and accessibility. Furthermore, UHC advancement requires intersectoral collaboration, recognizing that health is influenced by various determinants. Aligning fiscal and health policies through coordination with different departments can ensure that investments translate into measurable outcomes. Ultimately, sustained progress toward UHC in the Philippines depends not only on funding but also on strategic, data-driven governance and regional cooperation.

Oliver VAN HECKE [(1)], Marta WANAT [(2)], Aleksandra BOREK [(3)]

(1) Ghent University, Ghent, Belgique
(2) University Of Oxford, Oxford, Royaume-Uni
(3) Swps University, Warsaw, Pologne

Context: Primary care plays a critical role in antimicrobial stewardship (AMS), as most antibiotics are prescribed in this setting. Challenges to optimal use of antibiotics, such as diagnostic uncertainty, time constraints, and patient expectations, persist. Behavioural science can help identify the underlying factors driving behaviours (e.g., prescribing antibiotics) and guide the development and implementation of targeted, sustainable interventions.

Objectives: By the end of this workshop, participants will be able to: 1. Describe the context and challenges of AMS in primary care 2. Summarise evidence-based AMS interventions shown to improve prescribing in primary care 3. Understand the key principles of using a behavioural science approach to design/implement evidence-informed AMS interventions tailored to primary care

Teaching method and workshop: The workshop will combine short presentations with interactive, practice-focused activities. Brief lectures will introduce key AMS and behaviour-change concepts, while group activities and discussions will allow participants to share experiences and apply

Expected outcomes: The session will begin with a 15-minute introduction of the AMS challenges and interventions in primary care, supported by a Menti activity to gather participants' insights and experiences. This will be followed by a 30-minute segment on understanding and

Conclusion: Led by an academic GP and two behavioural scientists specialising in primary care and AMS, this workshop will equip participants with an evidence-based understanding of the challenges, behavioural determinants, and interventions related to antibiotic prescribing. It will allow participants to explore key AMS challenges and the behavioural factors that influence prescribing. Participants will have a chance to examine a real-world prescribing problem and consider practical intervention options suited to their own context. By bringing these elements together, the workshop aims to support participants in shaping more effective AMS approaches in primary care.

ID 1976- Severe Iron Deficiency Anemia in a Young Mother Identified During a Child-Focused Primary Care Visit: A Case Report

Rosa Maria GONZÁLEZ LÓPEZ, Paolo Augusto ROMERO MERINO, Carmen DE SANTIAGO GONZÁLEZ, Ayeiza Maria FELIPE LEMES

Centro De Salud Arrabal De Portillo, Valladolid, Espagne

Context: Cardiac amyloidosis is an underdiagnosed infiltrative cardiomyopathy that often mimics hypertrophic heart disease. Its recognition has major implications for patient outcomes, especially in older adults frequently managed in primary care.This case illustrates the diagnostic trajectory from an apparently benign hypertrophic pattern to confirmed transthyretin cardiac amyloidosis, emphasizing continuity of care and coordinated diagnostic pathways.

Methods: A 70-year-old man with hypertension, dyslipidemia, paroxysmal atrial fibrillation, and neuropathic pain attended a routine cardiology follow-up. He was asymptomatic. His medical history included incidental aortic and coronary calcification on CT, without prior cardiac structural disease.An ECG showed sinus rhythm with frequent supraventricular extrasystoles and nonspecific repolarization changes.Echocardiography revealed concentric left ventricular hypertrophy with a severe apical–basal gradient (2.3), preserved LVEF, and markedly reduced global longitudinal strain (–15.7%).Additional findings included grade III diastolic dysfunction, moderate left atrial dilation, thickened mitral and aortic valves with mild regurgitation, and a thin pericardial effusion. Right ventricular size and function were normal.Given the combination of concentric hypertrophy, reduced strain with apical sparing, and valvular thickening, the cardiologist suspected an infiltrative cardiomyopathy.A DPD-scintigraphy scan was ordered and demonstrated strong myocardial tracer uptake, confirming transthyretin cardiac amyloidosis. Laboratory tests excluded light-chain disease.The patient was referred to a specialized amyloidosis unit and started on disease-specific therapy, with continued shared follow-up between cardiology and primary care.

Originality: This case exemplifies the diagnostic challenge of differentiating hypertensive or age-related cardiac remodeling from amyloid infiltration, especially in asymptomatic patients.The presence of preserved ejection fraction with disproportionately reduced strain and apical sparing is highly specific yet frequently overlooked.

Lessons learned and future implications: Primary care clinicians often follow older adults with nonspecific symptoms or ECG abnormalities.Understanding red-flag echocardiographic features—apical sparing, concentric hypertrophy,and valvular thickening—may accelerate referral.Incorporating DPD-SPECT into diagnostic pathways enables non-invasive confirmation and timely therapy initiation.Improved awareness could reduce diagnostic delays.

Discussion: This case highlights the essential role of family medicine in longitudinal monitoring of older patients and integrating

subtle clinical changes.Early suspicion and coordinated referral optimized diagnostic accuracy.Amyloidosis screening should be considered in unexplained LV hypertrophy, especially with discordant strain findings.

Conclusion: Cardiac amyloidosis can present silently.Collaboration between primary care and cardiology is crucial for early identification,confirmation with DPD-scan,and initiation of disease-modifying treatment.

ID 628- Severe Malnutrition Revealing Superior Mesenteric Artery Syndrome: A Multidisciplinary Diagnostic Pathway from Primary Care

Rosa Maria GONZÁLEZ LÓPEZ, Paolo Augusto ROMERO MERINO, Carmen DE SANTIAGO GONZÁLEZ, Ayeiza Maria FELIPE LEMES

Centro De Salud Arrabal De Portillo, Valladolid, Espagne

Context: Septic shock originating from abdominal infections is a life-threatening emergency requiring rapid diagnosis,fluid resuscitation,and source control.Primary care professionals often identify early warning symptoms and coordinate transfer to emergency services.This case demonstrates the central role of primary care in early recognition,referral,and longitudinal follow-up of a patient who developed septic shock due to acute cholecystitis,ultimately requiring percutaneous cholecystostomy.

Methods: A 63-year-old man with type 2 diabetes,dyslipidemia,chronic kidney disease,and history of myocardial infarction presented to his primary care center with 12 hours of epigastric pain, fever, diaphoresis, and progressive hypotension.Examination revealed a positive Murphy sign and systolic blood pressure of 73 mmHg despite fluid resuscitation. Laboratory tests showed leukocytosis with neutrophilia, markedly elevated lipase, CRP , and procalcitonin.CT imaging revealed gallbladder wall thickening,pericholecystic fluid,and inflammatory changes consistent with acute cholecystitis. The patient was admitted to the ICU in septic shock requiring norepinephrine and broad-spectrum antibiotics. Surgery deemed him unstable for cholecystectomy; therefore, interventional radiology performed percutaneous cholecystostomy for source control.Bile cultures grew E.coli and Clostridium perfringens,guiding antibiotic adjustments.Gradually, vasopressor needs decreased,renal function improved,and the patient tolerated oral intake.Follow-up imaging confirmed catheter patency and resolution of inflammation.He was discharged with outpatient follow-up in internal medicine and primary care.

Originality: This case highlights a rare combination of acute cholecystitis complicated by severe septic shock,extreme lipase elevation without pancreatitis,and successful stabilization using percutaneous cholecystostomy when surgical intervention was contraindicated.

Lessons learned and future implications: Primary care plays a critical role in early recognition of septic shock,rapid referral,and coordination of care.Early imaging,prompt sepsis management,and interdisciplinary cooperation improved outcomes.Future practice may incorporate clearer referral pathways and early POCUS use in primary care to expedite diagnosis.

Discussion: Primary care clinicians are often responsible for distinguishing self-limited symptoms from early signs of severe infection. In this case , the family physician played a huge role identifying red flags such as persistent hypotension,diaphoresis and fever prompting early referral and fluid resuscitation.The case also highlights the potential role of POCUS in primary care. Bed side ultrasound could have expedited recognition of biliary pathology and fluid collection, reducing time to source control.

Conclusion: This case emphasizes timely recognition,coordinated management,and continuity of care as essential components for improving outcomes in severe abdominal sepsis.

Rosa Maria GONZÁLEZ LÓPEZ, Paolo Augusto ROMERO MERINO, Carmen DE SANTIAGO GONZÁLEZ, Ayeiza Maria FELIPE LEMES

Centro De Salud Arrabal De Portillo, Valladolid, Espagne

Context: Chest pain with ST-segment elevation usually triggers immediate activation of myocardial infarction protocols. However, non-ischemic causes such as pericarditis may mimic STEMI, creating diagnostic and management dilemmas for primary care and emergency clinicians. This case illustrates the importance of clinical reassessment and continuity of care within the Spanish public healthcare system.

Methods: A 65-year-old woman with dyslipidemia and hypothyroidism presented to her primary care center with acute chest pain. ECG revealed inferolateral ST elevation, leading to activation of the regional STEMI code and transfer to a coronary unit. She received aspirin and ticagrelor. On arrival, physical examination was normal. Repeat ECG confirmed inferolateral ST elevation, but troponin T remained normal. Echocardiography showed preserved LVEF without wall-motion abnormalities or pericardial effusion. Chest X-ray was unremarkable. Given the mismatch between ECG and biomarkers, cardiology revised the diagnosis to acute pericarditis. She was discharged on ibuprofen and colchicine with cardiology and primary care follow-up. Weeks later, the patient developed dyspnea. A chest radiograph showed a right-sided loculated pleural effusion with an air–fluid level, suggesting hydropneumothorax versus complicated effusion, along with bilateral parenchymal infiltrates. This required further evaluation and coordination between primary care, radiology, and hospital services.

Originality: This case combines two unusual features: focal inferolateral ST elevation mimicking STEMI and a late loculated pleural effusion after pericarditis. Together, they demonstrate an uncommon diagnostic trajectory not frequently described in primary care settings.

Lessons learned and future implications: ST elevation does not always represent STEMI; clinicians should consider pericarditis when biomarkers and echocardiography do not support ischemia. Primary care follow-up is essential, as complications such as pleural effusion may arise weeks later. Improved communication between healthcare levels enhances diagnostic accuracy. Incorporating point-of-care ultrasound into primary care may facilitate earlier detection of pericardial and pleural involvement.

Discussion: This case highlights the risk of premature diagnostic closure in STEMI activations. Clinical evolution, normal troponin, and absence of structural abnormalities prompted reconsideration. The late pleural complication underscores the systemic inflammatory nature of pericarditis and the role of longitudinal primary care monitoring.

Conclusion: This case underscores the importance of broad diagnostic thinking, interprofessional collaboration, and continuity of care in managing chest pain and its potential complications.

Context: Patient agitation, unplanned device removal, and restraint-related complications remain persistent safety challenges across hospitals, and long-term care facilities. Conventional restraint practices rely heavily on intermittent observation and subjective judgment, leading to delayed detection of escape attempts, pressure injuries, and physiological deterioration. Despite advances in digital health, few solutions integrate nurses' clinical insights, physiological monitoring,

behavioral assessments, and real-time decision support into a unified system.

Objectives: To develop an AI-enabled Multimodal Restraint Monitoring and Clinical Decision Support System (AI-MRM-CDSS) that unifies multimodal data to enable timely care and informed clinical decisions.

Methods: Built on a patented multimodal monitoring framework (Patent Application No. 114132XXX), an interdisciplinary team from nursing, engineering, and informatics designed AI-MRM-CDSS with three core components: (a)Clinical Input Interface that consolidates agitation assessments (RASS, GCS, CAM-ICU), pain scores, tubing status, medication information, and scheduled release intervals; (b)Embedded Sensor Modules within restraint bands that continuously capture heart rate, oxygen saturation, and pull-force patterns, which are wirelessly transmitted to the system's edge-computing unit for processing; (c)Edge-AI Analytics Engine providing real-time escape-risk predictions, restraint adjustment recommendations, tension-misuse alerts, medication-related insights, and automated reminders to support routine release and pressure injury prevention.

Results: The system architecture, interface, and multimodal sensing framework have been completed. Predictive algorithms are expected to identify escape attempts, trigger real-time alerts, and provide personalized recommendations on medication dosing and restraint use. Automated two-hour reminders will support timely repositioning and help prevent pressure injuries. Upcoming work includes algorithm refinement, simulation testing, and usability evaluations to assess predictive accuracy, alert relevance, workflow integration, and clinician acceptance.

Discussion: Integrating nursing expertise ensures that AI-generated recommendations align with actual clinical demands. By combining physiological signals, behavioral assessments, medication information, and tubing status, AI-MRM-CDSS addresses a long-standing gap in restraint safety by providing continuous monitoring, timely alerts, and actionable decision support to enhance patient safety.

Conclusion: AI-MRM-CDSS shows potential to enhance restraint safety and clinical decision-making. Its multimodal and scalable design allows application not only in hospitals but also in long-term care facilities. Planned testing and validation will further determine its utility across diverse care settings. Keywords: Artificial Intelligence, Decision Support System, Patient Safety, Physical Restraint

ID 1889- Shaping Family Medicine Through Preconference Exchange Program: XXX Experience

Maria PORTELA, Andrea ANDERSON, Emmeline HA, Joel WILLIS, Marcus DAVIS

George Washington University, Washington,dc, États-Unis

Context: When people talk about "building a new department," they usually mean org charts, budgets, and space. What almost never gets named is the moral question underneath: What kind of house are we building, and who will it hold? Aim To share what it looked like in practice to build a department around equity from day one, and what we learned about trust, culture, and structure along the way.

Methods: This is a reflective leadership case. Over the first three years, our leadership team used two anchors: Kotter's change-management steps and community-organizing principles I've relied on in other equity work. I tracked the major "architecture moves" we made—how we formed the guiding coalition, wrote the mission, set expectations for teaching and clinical work, designed governance, and communicated during times of uncertainty. I then looked at simple, real-world signals: who chose to join us, who stayed, how people showed up to meetings, and what themes surfaced in informal feedback and check-ins.

Originality: This is a leadership story about creating a family medicine department inside a large academic system while trying very deliberately not to reproduce the same hierarchies and inequities so many of us trained in. I frame it as moral architecture—seeing governance, voice, and equity as things you can actually design, not just hope for.

Lessons learned and future implications: Equity lives—or dies—in the structure. Co-ownership beats top-down messaging. Trust is slow to earn, fast to lose, and absolutely measurable.

Discussion: The choices that mattered most were not flashy: Governance that was actually transparent—people could see how decisions were made. Metrics we built with faculty, not for them. A mission and values statement faculty helped write, which changed the tone from "the department" to "our department." We hit bureaucracy, financial tension, and old power dynamics. But early engagement and retention were stronger than expected, and faculty described the space as "safer," "more honest," and "worth investing in."

Conclusion: Creating a department is not just an administrative act; it is an ethical one. When we treat medicine as moral architecture, we can build places where family medicine/practice—and the people who practice it—are more likely to survive and thrive.

ID 804- Shaping the future of primary care: GPs taking the liberty to initiate change

Liane Athayde BERINGHS-BUENO, Peterson VIEIRA BOTTARO, Vinicius ISAAC PIRES, Wilands Patrcio PROCOPIO GOMES

Einstein Hospital Israelita – Aps E Rede Assistencial, Sao Paulo, Brésil

Context: The Unidade de Assistência Médica Ambulatorial (AMA) Jardim Pirajussara, located in the southern region of São Paulo, Brazil, is a pre-hospital care facility managed since 2016 through a public-private partnership between the Einstein Hospital Israelita and the

Municipal Health Department. The unit performs approximately 14,000 monthly urgent and emergency consultations in Pediatrics and Internal Medicine, mostly low- and medium-complexity cases. This dynamic environment demands continuous strategic adaptation to ensure safety, efficiency, and clinical performance. In 2024, the unit initiated the certification process with the National Accreditation Organization (ONA), achieving accreditation in 2025. This advancement promoted structured governance, evidence-based protocols, enhanced training, and consolidation of a patient safety culture.

Methods: PDCA management cycle was implemented to strengthen leadership, clinical performance, and organizational alignment. • Plan: Diagnostic assessment identified disruptive behavior, technical errors, low adherence to leadership, and communication issues. An Ishikawa diagram identified root causes across workforce, methods, environment, materials, and leadership. • Do: Actions included individual action plans (PAI), structured feedback, continuous dialogue, ethics and clinical training, and institutional initiatives such as the "Medical Records Reminder Project." • Check: Indicators monitored included ≥95% compliant medical records, ≥95% protocol adherence, 90% reduction in prescription errors, ≥90% training participation, medical turnover ≤10% per year, and NPS improvement from –18.2 (Apr/2024) to +40.7 (Oct/2025). • Act: Interventions included procedure standardization, reallocation or dismissal of professionals posing care risks, revision of scheduling criteria, active listening groups, continuous audits, and reinforcement of reminder projects.

Originality: ONA auditors recognized the initiative as original and bold, highlighting the innovative application of classic quality tools focused on clinical leadership and performance improvement.

Lessons learned and future implications: PDCA cycle effectively addressed technical, behavioral, and relational challenges. Its structured approach strengthened leadership, supported evidence-based practice, and improved professional engagement, illustrating its potential as a strategic governance tool.

Discussion: Integrating ethical, technical, and behavioral components, PDCA contributed to culture transformation, error reduction, team cohesion, and alignment with institutional values through tools such as Ishikawa analysis, structured feedback, and mixed indicators.

Conclusion: Implementing PDCA at AMA Jardim Pirajussara demonstrated its utility as strategic clinical governance mechanism. ONA certification evidences structural and procedural improvements that sustain patient safety and high-quality care.

Context: Klinefelter syndrome (KS) is the most common sex chromosome aneuploidy in men and is frequently underdiagnosed. Sexual dysfunction, including erectile dysfunction (ED), decreased libido, and delayed ejaculation, may arise from androgen deficiency, but vascular and psychosocial factors often coexist. In primary care (PC), understanding and coordinating these dimensions is crucial.

Methods: We present the case of a 46-year-old male with KS followed in PC since 2003. Clinical information was collected from endocrinology, urology, and vascular surgery. The patient was diagnosed with primary hypogonadism after bilateral testicular surgery for epidermoid cysts, with histology showing a Sertoli-cell-only pattern; cytogenetics later confirmed 47,XXY. Intramuscular testosterone was initiated, with adequate libido but persistent ED, delayed

ejaculation, and performance anxiety. He developed obesity, dyslipidemia, and peripheral arterial disease. Trials of PDE-5 inhibitors gave inconsistent benefit, and psychogenic factors contributed. Management considerations included cardiovascular risk optimization, alternative testosterone formulations, lifestyle changes, and psychosexual counseling. Strengths include long-term multidisciplinary follow-up; limitations include lack of standardized outcomes and variable adherence.

Originality: Although sexual dysfunction is recognized in KS, reports seldom detail the interplay of mechanisms in PC. This case shows that ED in KS extends beyond hypogonadism and highlights PC's role as the coordinator for multidisciplinary and psychosocial care.

Lessons learned and future implications: Routine assessment of sexual function in KS is essential, as persistent ED often reflects multifactorial causes. PC can integrate hormonal, cardiovascular, lifestyle, and mental health interventions. Future practice should include early vascular screening, individualized testosterone delivery, and structured psychosexual support, while avoiding assumptions that all symptoms stem from KS.

Discussion: ED in KS is a multidimensional condition requiring coordinated care. PC clinicians are well positioned to synthesize specialist input, manage comorbidities, and address psychosocial contributors, improving diagnostic accuracy, outcomes, and long-term well-being.

Conclusion: ED in KS is rarely attributable to a single mechanism. A holistic, interdisciplinary PC approach can optimize sexual function, quality of life, and long-term health. This case reinforces the importance of systematic evaluation of sexual dysfunction in KS.

Binta DIALLO [(1)] , Antoine MAHÉ [(2)]

(1) Doctor, Strasbourg, France
(2) Professor, Colmar, France

Context: In clinical practice, healthcare professionals increasingly encounter patients from diverse cultural and geographic backgrounds. Despite universal healthcare access, several studies report poorer perceived health among immigrant populations and individuals from French Overseas Departments and Territories. Beyond structural and socioeconomic factors, this study explores whether cognitive mechanisms within medical reasoning contribute to these disparities.

Objectives: To identify cognitive biases influencing the clinical reasoning and management of patients of non-European origin.

Methods: A qualitative study was conducted between March and September 2024 using semi-structured interviews with eleven physicians practicing in mainland France and the overseas departments. Data were analyzed thematically using a grounded theory approach to model how biases arise during clinical reasoning.

Results: Interviews revealed that cognitive biases emerge at several key stages of patient care. Initial interactions were often hindered by linguistic barriers, limiting the collection of clinical information. During data integration, physicians' emotions, experiences, and structural context intersected with cultural and socioeconomic factors, shaping their interpretations and decisions. Focusing on patients of non-European origin, we identified specific cognitive biases, including difficulties recognizing dermatological signs on darker skin tones, diagnostic overshadowing related to cultural assumptions, and the influence of stereotypes on pain assessment. Despite these challenges, many physicians demonstrated reflexivity and efforts to question their reasoning and the cognitive processes affecting their practice.

Discussion: Methodological rigor was ensured using the COREQ checklist. Nevertheless, snowball sampling may have introduced a selection bias toward motivated respondents. To address potential investigator subjectivity

and social desirability bias, the interview guide was iteratively refined. Recall and information biases, inherent to participants' narratives, were acknowledged as consistent with qualitative research dynamics.

Conclusion: Cognitive biases are inherent to medical decision-making and can be reinforced by patients' ethnic or cultural categorization. These biases contribute to unequal care by influencing diagnosis and treatment decisions. Raising awareness among healthcare professionals and institutions about these mechanisms, and integrating training on cognitive biases and cultural competence are essential strategies to improve equity in healthcare delivery, particularly for non-European patients.

Maher BEN HAMIDA, Rebeh BOUGOSSA, Asma BEN MABOUK, Jihene CHELLI, Fatma LARBI

Department Of Endocrinology, Internal Medicine And Infectious Diseases, University Hospital Of Mahdia, Mahdia, Tunisie

Context: Cutaneous leishmaniasis (CL) is a wide-reaching infection of major public health concern. In Tunisia, the disease is endemic in the south and the center of the country. However, new endemic areas are being reported.Cutaneous leishmaniasis (CL) is a wide-reaching infection of major public health concern. In Tunisia, the disease is endemic in the south and the center of the country. However, new endemic areas are being reported.

Objectives: This study aimed to describe the epidemio-clinical features of CL in the region of Mahdia.

Methods: A retrospective study was conducted in the department of infectious diseases and internal medicine in the university hospital of Mahdia during 6 years (2017 – 2023) including all patients hospitalized for CL and presented an indication for systemic treatment. Diagnosis of CL was made clinically and confirmed by visualizing the amastigotes in microscopic examination of infected tissue.

Results: A total of 15 patients were enrolled in the study: 11 men and 4 women. The median age was 53.5 years old (36 – 73 years old). Diabetes mellitus was the most common comorbidity (33.3%). Lower and upper extremities were affected in 73.3% and 60% respectively. The median number of lesions was 5 (1 - 9 lesions). Ulcero-crusted cutaneous lesions were the most common form (80%). Systemic antimonials were the most common monotherapy regimen prescribed in 10 cases (66.6%). Metronidazole was prescribed in the other cases (33.3%). The outcome was favorable in all cases.

Discussion: In this series from a non-endemic region, CL mainly affected middle-aged patients, often with diabetes, and presented as multiple ulcero-crusted lesions. Systemic antimonials remain the first-line treatment for cutaneous leishmaniasis, while other drugs such as metronidazole also proved effective in our study. These findings highlight the need for clinicians working in non-endemic areas to remain vigilant for CL and to promptly seek microbiological confirmation in suspected cases.

Conclusion: Even in non-endemic areas, the physicians should make the diagnosis of CL in front of a high clinical suspicion and then confirm it microbiologically.

Context: Smart devices can be a powerful adjunct for learning in clinical settings, but

students are uncertain about the acceptability of using them openly.1

Objectives: We aimed to explore how medical students use point of care information systems in the clinical setting and for self-directed learning. During this study, it emerged that students receive mixed messages from clinical teachers about the use of handheld devices during clinical placement which can lead to confusion and covert use. We discuss these findings and how to address device use during clinical learning opportunities.

Methods: This qualitative study used a convenience sample of 13 fifth-year medical students, who had started consulting independently whilst on General Practice placements. We held three in-person focus groups using a semi-structured topic guide between February and April 2025. Transcripts were anonymised and thematic analysis was performed using a coding template guided by self-directed learning theory.2

Results: Students reported using handheld devices on clinical placement to quickly access information which allowed them to feel "more included with the team," especially to aid their understanding when educators were "really busy." However, several students felt uncomfortable using their phone during placement as "a lot of the doctors would get quite annoyed with you," resulting in covert or "sneaky" use, with some students feeling that alternative devices such as iPads may "look slightly better than using a phone." In contrast, other students experienced role models who used handheld devices, including phones, to support clinical decision-making.

Discussion: Our results suggest that students use handheld devices to enhance clinical education as it allows them to make sense of their observational learning in real time. However, this study supports previous findings that educators display mixed attitudes towards students' device use in clinical settings.3,4 Students would benefit from clear expectations upfront and consistent messaging around this, relevant to the learning context and setting. Perception of supplementary devices like tablets as more professional than phones may deepen financial inequalities for students who cannot afford them.

Conclusion: Handheld devices are a valuable learning resource in the clinical setting, but their use is not yet normalised. Students need an agreed etiquette.

(1) Reckitt Benckiser, Kingston Upon Hull, Royaume-Uni
(2) University Of Huddersfield, Huddersfield, Royaume-Uni
(3) University Of Huddersfield, University Of Huddersfield, Royaume-Uni

Context: Pharyngitis and acute cough are common symptoms of URTI (Upper Respiratory Tract Infection) that cause significant distress to sufferers. Herbal medicines such as P. lanceolata are commonly used to address these symptoms but research into their mechanism of action is limited. Any anti-bacterial effect of P. lanceolata is also unknown but may be of benefit to URTI patients.

Objectives: To asses the impact of a syrup containing P. lancolata on the growth and adhesion of a common URTI causing bacteria (S. pyogenes) in an in vitro model.

Methods: Streptococcus pyogenes Rosenbach was purchased from Culture Collections, UK Health Security Agency (Salisbury, UK). Each well of a sterile flat-bottomed 96-well microtiter plates contained 10 µL of the Plantago lanceolata extract syrup concentrations together with 190 µL of Streptococcus pyogenes inoculum (5 × 103 CFU/mL). The plate was then incubated for 16 h. After incubation, antibacterial activity was evaluated with the BacTiter-Glo™ microbial cell viability assay (Promega). Luminescence was measured with a microplate reader. Bacteria in mid-log phase were grown in Brain Heart Infusion Agar at 37°C overnight and washed three times with PBS. BEAS-2B cells were

treated with non-toxic concentrations of Plantago lanceolata extract syrup (12.5, 25 and 50 µg/mL) for 1 h, followed by washing with PBS. Control cells were treated with sterile water. Streptococcus pyogenes (1 x 106) were incubated in Hanks' balanced salt solution/1% foetal bovine serum for 1 h and added to a 96-well plate containing BEAS-2B cells. After 1 h incubation with gentle shaking, BEAS-2B cells were washed with PBS to remove unbound bacteria. Luciferin (12.5 µM) was added to the cells, and luminescence measured.

Results: P.Lanceolata syrup at concentrations of 12, 25 & 50 ug/ml significantly (P=<0.05-determined by one-way ANOVA) reduced S.Pyogenes growth and adhesion, vs control.

Discussion: These results demonstrate a novel mechanism of action for P. lanceolata suggesting that this preparation may be able to prevent the adhesion and growth of URTI causing bacteria.

Conclusion: The in vitro data is novel and suggest that the benefit of using P. lanceolata may go beyond simple symptomatic relief and could provide benefit to patients at risk of bacterial URTI.

ID 927- Six Years of Evolution in Remote Care: From Experiment to Integrated Virtual Clinic Model in Primary Care

Catia NICODEMO

Oxford Unviersity, Oxford, Royaume-Uni

Context: Access to General Practitioners (GPs) is essential for delivering timely, high-quality primary care, yet GP availability varies widely across the UK. Underserved regions experience poorer clinical outcomes, lower patient satisfaction, and greater pressure on hospital services.

Objectives: This study aims to examine the determinants of GP career and location choices, quantify how GP distribution affects primary care quality, and evaluate the effectiveness of recruitment and incentive policies designed to address workforce shortages. Specifically, the study investigates: (1) how educational, demographic, and geographic factors shape newly qualified GPs' location decisions; (2) how variation in GP-to-patient ratios influences clinical quality indicators such as QOF scores, prescribing behaviour, and patient experience; and (3) which financial and non-financial incentives effectively attract GPs to shortage areas.

Methods: The study uses a linked longitudinal dataset combining UK Medical Education Database (UKMED) records with NHS Digital workforce, GP Patient Survey, Quality and Outcomes Framework (QOF), and prescribing data. A mixed logit discrete choice model will analyse practice location choices. Causal impacts of GP distribution on quality will be estimated using an instrumental-variable strategy based on registrar density. A structural random-coefficient discrete choice model will assess the effectiveness of policies such as the Targeted Enhanced Recruitment Scheme and widening-participation scholarships. Counterfactual simulations will estimate distributional and equity effects.

Results: We anticipate identifying key educational, demographic, and training-related predictors of GP practice location. Preliminary analysis is expected to show that lower GP-to-patient ratios are associated with reduced QOF performance, higher prescribing intensity, and poorer patient satisfaction. Policy simulations are anticipated to demonstrate that targeted financial incentives and widening-participation pathways can increase GP uptake in underserved regions, with heterogeneous effects across subgroups.

Discussion: Understanding GP labour-market behaviours and the causal impacts of GP availability will support evidence-based workforce planning. The findings will contribute to health economics and policy research on healthcare supply, spatial inequality, and labour-market incentives.

Conclusion: This study will generate robust evidence on the drivers and consequences of GP distribution, informing equitable and cost-effective policies to reduce regional inequalities in primary care access.

ID 839- Sleep Hygiene Disorder as the Underlying Cause of Chronic Insomnia: The Importance of a Holistic Approach in Primary Care

Solène BLANCHIN

Université Grenoble Alpes, Grenoble, France

Context: Narrative medicine is an emerging discipline that emphasizes listening to patients' stories through a structured pedagogical approach designed to strengthen relational skills. Previous studies have shown associations with increased empathy and reflexivity, as well as reduced burnout, but little is known about the long-term persistence of these effects. In 2014–2015, XXX University introduced the first mandatory narrative medicine module, for 400 fourth-year medical students.

Objectives: To explore the impact of that training on their professional practice ten years later.

Methods: We conducted a qualitative study using semi-structured individual interviews with physicians who had taken the mandatory course in 2014–2015. Data were analyzed using an approach informed by interpretative phenomenological analysis.

Results: Ten former students participated. They described a lasting influence on their practice, including attentive listening, enhanced empathy, expression of emotional experiences, and a stronger reflexive stance. Thematic analysis identified seven superordinate themes: expressing emotions to improve care; valuing listening as a therapeutic act; underestimating the course due to exam prioritization and limited conceptual clarity; requiring practical and sustained application of narrative medicine; reconciling academic demands with humanistic training; envisioning narrative medicine collections for patients and clinicians; and valuing experiential learning.

Discussion: To our knowledge, this is the first study to show that the effects of narrative medicine can persist ten years after training, despite methodological limitations related to the relatively brief interview duration (mean 37 minutes). The skills described align closely with those expected in general practice, emphasizing patient-centered listening and attention to patients' lived experiences. These findings also provide insights for developing training in qualitative research within primary care. The use of standardized tools, such as the Narrative Competence Scale, may further strengthen the assessment of narrative medicine's impact.

Conclusion: Ten years after their training, physicians still retain a lasting imprint of narrative medicine. They highlight attentive listening, reflexivity, and emotional expression as key resources for professional fulfilment. Integrating this approach progressively and consistently into the medical curriculum—together with aligned assessment strategies—may enhance its impact and foster more humane and relationally attuned care.

(4) Universidade Federal Do Rio Grande Do Norte, Caicó, Brésil

Context: Monitoring births and their maternal and neonatal characteristics is essential for maternal and child health surveillance, and Brazil's Live Birth Information System (SINASC) provides standardized national data on prenatal care, delivery characteristics, and newborn outcomes, although substantial regional disparities persist in access, adequacy of care, cesarean rates and neonatal outcomes, reflecting broader socioeconomic inequalities.

Objectives: To describe the sociodemographic, obstetric, and neonatal profile of live births in

Brazil in 2024 according to the five macro-regions.

Methods: A descriptive ecological study was conducted using aggregated SINASC data for 2024, considering the North, Northeast, Southeast, South and Center-West as analytical units; variables were grouped into sociodemographic (maternal age, education, marital status), obstetric (gestational age, pregnancy type, number and adequacy of prenatal visits, delivery type, Robson groups) and neonatal outcomes (Apgar scores, birth weight, congenital anomalies); data were extracted via TabNet/DATASUS, organized in Excel and described using frequencies, proportions and regional comparisons.

Results: Brazil recorded 2,384,438 live births in 2024, with the Southeast accounting for 37.9% and the Northeast for 27.9%; adolescent motherhood was highest in the North (22.3%) and Northeast (19.7%), while mothers aged ≥35 years were more common in the Southeast and South; maternal education showed marked inequalities, with higher schooling concentrated in the South/Southeast; prenatal care coverage (≥7 visits) reached 85.5% in the South and 82.3% in the Southeast but only 64.9% in the North, and “more than adequate” care exceeded 75% in the South/Southeast but was 55.7% in the North; cesarean sections comprised 60.6% of all births, reaching 66.6% in the Center-West; preterm birth and low birth weight were slightly higher in the North and Northeast, while Apgar scores at 5 minutes were high nationwide (>96%); congenital anomalies occurred in 1.1% of births with minimal variation.

Discussion: The findings reveal persistent regional inequalities in prenatal care adequacy and birth outcomes, with less developed regions presenting poorer indicators despite high national coverage.

Conclusion: Brazil has progressed in prenatal and perinatal monitoring, but significant inequities persist, requiring strengthened primary care, improved prenatal care quality and structural actions to reduce territorial vulnerabilities.

Context: Prenatal care is a key strategy to reduce maternal and perinatal morbidity and mortality, yet important regional inequities persist in Brazil. The ratio between the number of prenatal consultations and live births (PN/NV) is a synthetic indicator of coverage and intensity of gestational follow-up.

Objectives: To analyse the ratio between the number of prenatal consultations and the number of live births in Brazil from 2008 to 2023 by macro-region.

Methods: Ecological time-series and spatial study using secondary data aggregated by federative unit and region. Annual numbers of live births were obtained from the Live Birth Information System and prenatal consultations from the Outpatient Information System of the Unified National Health System. We calculated the PN/NV ratio for each federative unit and year and built choropleth maps for 2008, 2011, 2014, 2017, 2020 and 2023. For 2024, we described the distribution of consultations by professional category based on Brazilian Occupational Classification codes. Analyses were descriptive.

Results: The PN/NV ratio increased in all regions until the mid-2010s, followed by relative stability and a marked decline in 2020, with partial recovery by 2023. Throughout the series, South and Southeast showed the highest ratios, while North and Northeast remained below the national average and were more affected during the COVID-19 pandemic.

In 2024, nurses accounted for 46.3% of prenatal consultations in Brazil, reaching 68.0% in the Northeast and 61.3% in the North; general practitioners and family physicians performed 27.5% of visits, predominating in the Centre-West (39.8%) and South (34.7%); and maternal-child and gynaecology-obstetrics specialists were responsible for 26.1% of consultations, mainly in the Southeast (45.9%).

Discussion: The combination of PN/NV ratios and spatial analysis highlighted a persistent pattern of regional inequality in prenatal care intensity, exacerbated but not created by the pandemic and linked to unequal distribution of services and workforce.

Conclusion: Despite advances in prenatal coverage, Brazil still exhibits marked spatial and professional disparities. Strengthening primary care in vulnerable territories and valuing the nursing workforce are essential to ensure more equitable and continuous prenatal care.

ID 862- Social Prescribing and Lifestyle Medicine: A Practical Framework for Family Physicians .Exchange of experiences

Anna ANDRES LORCA, Elisabet DESCALS SINGLA, Sara RODOREDA NOGUEROLA, Albert BOADA VALMASEDA, Estela DIAZ ALVAREZ, Mireia FABREGAS ESCURRIOLA, Leonardo MENDEZ BOO

Institut Català De La Salut, Barcelona, Espagne

Context: Since 2022, Catalonia's primary care system has incorporated new professional roles to strengthen multidisciplinary care: emotional well-being referents (psychologists), physiotherapists, dietitians-nutritionists, and dental hygienists. This initiative aims to improve population health and expand preventive and community-based services. Objective: To describe the implementation of these roles and assess their impact on group activities, community interventions, and social prescribing within the Catalan Health Institute.

Methods: A descriptive analysis was conducted using data from the Primary Care Information System. Indicators included the number of group and community activities, participation rates, and selected health outcomes associated with interventions led by the new roles.

Originality: Since its implementation, there has been a notable increase in group activities compared to the pre-pandemic period. Likewise, community activities and social prescribing have experienced significant growth. Individuals supported by emotional well-being professionals show improvements in anxiety symptoms and quality of life, while patients with chronic low back pain demonstrate progress in functional tests. Physiotherapy interventions help reduce pain and improve mobility, and dietary programs promote metabolic control and weight reduction in at-risk populations.

Lessons learned and future implications: The incorporation of these roles has transformed primary care in Catalonia, fostering multidisciplinary collaboration and strengthening community health strategies.

Discussion: The increase in group and community activities reflects a shift toward proactive, preventive care models.

Conclusion: New professional roles have expanded care capacity, improved health outcomes, and promoted community engagement. Continuous monitoring will be key to ensuring sustainability and guiding future scaling.

ID 1505- Socio-Demographic Gaps in LLM-Guided Pain Management

Eloïse DAHAN

Chu Sud Réunion, Saint Pierre, France

Context: Hyperventilation syndrome (HVS) appears to be overrepresented among patients with chronic pain. Several pathophysiological mechanisms may contribute to maintaining pain in these individuals. However, existing studies show considerable heterogeneity regarding patient populations and screening methods.

Objectives: The primary objective of this study was to determine the prevalence of HVS among patients attending the Pain Evaluation and Treatment Center at XXX University Hospital, using the Nijmegen Questionnaire. Secondary objectives were to identify associated factors and to explore correlations with anxiety–depression symptoms and fibromyalgia severity.

Methods: We conducted a retrospective, descriptive, observational study including all first-time patients seen at the Pain Evaluation and Treatment Center of Sud Réunion University Hospital between October 1, 2024, and March 31, 2025.

Results: A total of 121 patients were included. HVS screening was positive in 81% of cases. All patients with nociplastic pain (fibromyalgia and myofascial pain syndromes) screened positive for HVS ($p < 0.0001$). Female patients were significantly more likely to have a positive HVS screening result ($p < 0.01$). The Nijmegen score was positively and significantly correlated with the Hospital Anxiety and Depression (HAD) Scale-anxiety score ($p < 0.001$), the HAD Scale-depression score ($p < 0,01$) and the American College of Rheumatology (ACR) fibromyalgia severity score ($p = 0.009$).

Discussion: HVS appears highly prevalent in chronic pain compared with the general population, particularly in cases of nociplastic pain. Research in fibromyalgia proposes a link between impaired tissue oxygenation and chronic pain. Hypocapnia, consequence of HVS, reduces tissue oxygenation through the Bohr effect and vasoconstriction. In conditions involving central sensitization, the NMDA receptor becomes increasingly responsive to glutamate. Studies suggest elevated glutamate concentrations in the brains of individuals with fibromyalgia. Because poor tissue oxygenation can lead to excessive glutamate accumulation, this supports the hypothesis connecting tissue hypoxia with neuromuscular hyperexcitability. Taken together, these findings suggest a potential vicious cycle between chronic hyperventilation syndrome and nociplastic pain

Conclusion: HVS is a frequent comorbidity among patients with chronic pain, particularly those with nociplastic pain, suggesting its potential involvement in the sensitization of pain pathways

ID 1036- Socioeconomic Barriers Affecting Equity in Primary Health Care in Panama

Holly YOUNG [(1)] , Anistta MAHESWARAN [(1)], Poorvi SRIVASTAVA [(1)], Miranda VOSS [(2)]

(1) Department of Primary Care And Public Health, School Of Public Health, Imperial College London, 90 Wood Lane, London W12 0bz, London, Royaume-Uni
(2) Medical Education Innovation And Research Centre, school Of Public Health, Imperial College London, 90 Wood Lane, London W12 0bz, London, Royaume-Uni

Context: Medical students have many online learning resources to select from for self-directed learning which could feel overwhelming to navigate.

Objectives: We aimed to explore medical students' attitudes and use of online point of care information systems for learning. During this study students discussed many other online learning resources. Here we report the digital information landscape described by students.

Methods: We conducted three in-person focus groups using a semi-structured topic guide between February and April 2025. A convenience sample of thirteen fifth-year medical students was recruited from XXX medical school. These students had begun to consult independently during their General Practice placements. Anonymised transcripts were thematically analysed using a coding template guided by self-directed learning theory.

Results: Medical students reported using a vast array of online resources for learning. During the three focus groups, thirteen students commented on 59 online resources. These are shown in the word cloud in Figure 1. Several students reported feeling overwhelmed by the range of possible information sources and wished: 'to be taught like how to use' and 'navigate these websites', 'because sometimes there are really, really good resources, but we just don't know how to find them'. Barriers to

resource usage included accessibility, phone storage issues, needing to login, and cost. Participants also commented that: 'you have to pay for everything' 'It adds up' 'it's a bit unfair for people that like can't afford it'. One student expressed a desire for the university to subsidise resources.

Discussion: These findings support calls for medical schools to provide guidance about online learning resources, and consider mitigating inequalities driven by cost barriers through solutions such as subsidisation.

Conclusion: Medical students have many online resources available for learning, but paywalls may exacerbate learning inequalities. Clinical educators can better support students to navigate this crowded digital information landscape, by deliberately including guidance about how to select, use and learn from online resources in their teaching sessions.

ID 785- Socioeconomic profiles and cardiovascular risk according to three evaluation tools in primary care patients

Wei-Cheng WANG, Ju-Chien JENG, Po-Tsung HUANG

China Medical University Hospital, Taichung City, Taïwan

Context: Trichuris trichiura infection has become rare in Taiwan due to decades of public health improvements, yet it remains prevalent in many tropical countries. As global workforce mobility increases, primary care physicians may increasingly encounter imported parasitic infections in asymptomatic individuals. This case illustrates a scenario relevant to routine health examinations and emphasizes the role of family physicians in early detection, risk assessment, and patient counseling.

Methods: A 53-year-old Taiwanese man underwent a self-paid health check-up after several years of employment in the Philippines. He denied gastrointestinal symptoms. Screening colonoscopy revealed a slender, motile worm attached to the ascending colon mucosa. Endoscopic removal was performed, and histopathology confirmed T. trichiura through characteristic nematode morphology and barrel-shaped eggs with bipolar plugs. Laboratory tests, abdominal ultrasonography, chest radiography, pulmonary function testing, and esophagogastroduodenoscopy showed no infection-related abnormalities. The patient received mebendazole 100 mg twice daily for 9 days. Stool testing was recommended but not completed due to loss to follow-up.

Originality: Although T. trichiura infections are well described, incidental detection in a low-prevalence region, coupled with comprehensive evaluation in an asymptomatic adult, provides a unique clinical perspective relevant to family medicine. The case highlights how opportunistic screening—common within general practice health check programs—can reveal imported infections even in individuals without symptoms.

Lessons learned and future implications: This case underscores the critical importance of detailed travel and occupational histories during routine primary care visits. It also illustrates the challenges in ensuring patient adherence to follow-up when symptoms are absent. The case encourages clinicians to maintain clinical suspicion for parasitic infections in returning workers and to develop practical strategies to enhance follow-up testing and treatment verification.

Discussion: Colonoscopy provides both diagnostic and therapeutic utility in intestinal helminthiasis. Extended mebendazole regimens may improve eradication rates but require stool confirmation. As international mobility rises, clinicians in low-prevalence countries must anticipate re-emerging parasitic diseases.

Conclusion: This case offers transferable insights for general practice, demonstrating the value of thorough history-taking, appropriate use of screening tools, and proactive management of asymptomatic imported infections in primary care.

Context: Medical professionals encounter various occupational hazards, such as workplace violence. To help address these challenges, medical education aims to foster a professional practice grounded in strong interpersonal relationships and a comprehensive, integrative understanding of health.

Objectives: Given the scarcity of studies examining reports of workplace violence in the medical field, this cross-sectional study aimed to determine the prevalence of physical, psychological, and sexual violence among medical professionals working in the city of São Paulo in 2023.

Methods: This cross-sectional, quantitative, descriptive, and retrospective study included all 122 medical professionals who experienced violence and whose cases were reported in the Information System for Violence and Accident Surveillance (SIVVA) of the São Paulo Municipal Health Department. SIVVA documents incidents of accidents and violence using standardized notification forms for both suspected and confirmed cases. Data collection covered the period from January to December 2023.

Results: In 2023, a total of 122 cases of work-related violence against medical professionals were reported in the city of São Paulo. Regarding the sex of the victims, 36.1% were male and 63.9% were female. Third parties were responsible for 98.4% of the violent incidents, while 1.6% were self-inflicted. As for the type of violence, 22.9% was physical, 75.5% psychological, and 1.6% sexual.

Discussion: The daily work routine is often marked by episodes of violence, which bring implications for the organization of work: absence from work, resignation, impacts on the quality of care, and an increase in service demands. It is important that, in this context where users needs are recognized, the professional team carries out health practices that foster welcoming care.

Conclusion: In the city of São Paulo, during 2023, a total of 122 cases of violence against physicians during their professional activities were reported. The physicians who were victims of violence were predominantly young women, and the most frequent type of violence was psychological. Among the reported cases of violence against medical professionals, 51.6% were not accompanied by an official Work Accident Report (CAT). Professionalism represents a key component in medical education, contributing to the qualification of healthcare professionals and the strengthening of public health policies.

Context: Retinal tears are vision-threatening conditions that may develop after physical exertion, trauma, or vitreoretinal traction. They require rapid identification to prevent progression to retinal detachment. Primary care physicians frequently serve as the first

point of contact when patients present with sudden visual disturbances, making their role in recognizing early warning signs essential.

Methods: A 33-year-old woman presented to a family health center after running, reporting sudden flashes of light and dark floaters in her right eye. She had no history of trauma or eye disease. The external eye examination was normal, and gross visual acuity was preserved, although a detailed assessment was not possible. Due to symptoms suggestive of a retinal tear, she was urgently referred to an ophthalmologist. The main strength of management was the quick recognition of red-flag symptoms and immediate referral, reducing the risk of delayed diagnosis. The key limitation was the limited diagnostic capacity in primary care. Nevertheless, a timely specialist evaluation demonstrated effective triage.

Originality: While retinal tears are well documented, reports of exertion-related cases presenting first to primary care are relatively scarce. Existing literature often focuses on trauma-related mechanisms, whereas this case highlights the importance of assessing non-traumatic but sudden visual symptoms following physical activity. The case contributes a unique perspective by illustrating how a primary care clinician, without advanced tools, can still make a critical early diagnosis based solely on symptom recognition.

Lessons learned and future implications: The case reinforces that sudden photopsia or floaters, even in the absence of trauma, should prompt urgent consideration of retinal pathology. Primary care physicians must maintain clinical vigilance and be prepared to act quickly when such red flags arise. Incorporating training modules or decision aids could further improve recognition and referral pathways, enhancing patient safety.

Discussion: This case emphasizes the crucial role of primary care in early detection of retinal tears. Strengthening communication between primary care services and ophthalmology clinics may reduce delays and improve patient outcomes.

Conclusion: Rapid identification and referral of acute visual symptoms in primary care can prevent retinal detachment and preserve long-term vision, highlighting the broader significance of early clinical suspicion.

Context: Health-risk behaviors often emerge or intensify during adolescence, potentially persisting into adulthood and contributing to increased morbidity and mortality. Among these behaviors, the use of electronic smoking devices (ESDs) has become increasingly prominent. The southern region of São Paulo, Brazil, is characterized by high levels of social vulnerability—with 59.3% of its population dependent on the public health system, 24.3% residing in informal urban areas, and a significant proportion of young people identifying as Black or mixed race

Methods: The health education intervention was carried out between April and May 2025 in public schools located in the southern region of São Paulo, involving students aged 13 to 17 years (approximately 360 participants). The activities were developed within a university extension program associated with Family and Community Medicine, recognizing the school as an integral part of the community. The process included group discussions, educational materials, and open debates addressing risk factors and social determinants of health, fostering critical reflection and

empowering students toward self-care and informed decision-making regarding the use of drugs, alcohol, and tobacco (DAT). Limitations included the short duration of the intervention and challenges in assessing long-term behavioral changes.

Originality: This experience was innovative in integrating the school environment as a territory of care, strengthening the connection between health and education.

Lessons learned and future implications: The experience highlighted the importance of public policies for social protection, the monitoring and regulation of emerging tobacco products, and the implementation of intersectoral strategies aimed at improving adolescents' living and health conditions.

Discussion: The intervention demonstrated that the school environment represents a privileged setting for health promotion and disease prevention initiatives, particularly when coordinated with primary health care. The experience supports existing evidence on the effectiveness of community-based health education among adolescents in socially vulnerable contexts.

Conclusion: The findings indicate that health education initiatives in schools, when articulated with primary health care, highlight the potential of educational institutions as spaces for care and health promotion, integrating efforts across education, health, and community.

ID 348- Speaking up – your chance to understand and expand how WONCA makes policies that work for family medicine.

Sofica BISTRICEANU

Aphc, Wonca, Tg. Neamt, Roumanie

Context: Background Professionals in the healthcare industry interact with their collaborators, sharing the quality of their products. End users can be satisfied or dissatisfied with their providers, depending on the level of professionalism they exhibit. Hearted work encourages people's cooperation and enhances their lives, in contrast to cool-hearted work. Aim To highlight the consequences of cool-hearted work in clinical practice and how heartened work benefits individuals.

Methods: The author conducted a qualitative study in the community from 2023 to 2025, examining the impact of provider-customer interactions on their lives.

Originality: Findings Providers' disheartened work disappoints the end users, making them less involved in the therapy plans, which leads to poor clinical outcomes. Typically, customers seek another provider from the available options for the next episode of care, which decreases the provider's return on investment and negatively impacts their practice standing, career path, reputation, and financial stability. Action taken The author initiated informative programs in the community to promote the value of heart-centered work for business growth and personal well-being.

Lessons learned and future implications: Professional interactions between parties in a relationship enhance individuals' professional, social, and personal lives.

Discussion: AI in customer sentiment analysis predicts loyalty toward the provider, the evolution of return on investment, the practice's standing, financial capabilities, the provider's reputation, and career advancement opportunities. Hearted work is essential for enhancing relationships and individual lives. Informative programs relating to these issues are required.

Conclusion: Effective communication in sharing products or services is crucial for attracting customers, enhancing their experience, and ensuring business stability and personal growth.

Context: WONCA Europe's vision is to improve the quality of life of people through fostering high standards of care in general practice based on solidarity, equity, and person-focused care. Last decade, there is progress in infrastructure of general practice in many European countries but structural and organizational challenges remain, particularly due to increasing demands from healthcare and society and constraints in workforce. Therefore, it is important to formulate a vision for the future. As an example, XXX professional general practice societies launched a Vision XXX providing long-term goals and actions for sustainable primary care. This workshop explores GP views and perspectives on addressing the main challenges in general practice by providing an interactive platform to co-create practical roadmaps for local implementation considering the context of the healthcare system. This workshop combines our lessons learned with participants' own experiences. The goal is collective learning and identifying key drivers for successful development and implementation of strategic visions in primary care.

Objectives: - Exchange and integrate lessons learned to strengthen collective insight into effective strategies for sustainable primary care. - Translate high-level vision elements into prioritized, phased actions suitable for diverse contexts. - Construct an implementation roadmap with measurable outcomes and success indicators.

Teaching method and workshop: Teaching methods: - Interactive small-group work - Facilitated plenary discussion Workshop schedule: 0–10 min: Introduction vision XXX and lessons learned in development and implementation. 10–35 min: Current state scan & roadmap building. 35–55 min: Pl

Expected outcomes: Participants will formulate core principles for effective development and implementation of a high-level vision and identify context-specific strategies. In addition, they will benefit from exchanging diverse international perspectives and experiences.

Conclusion: Developing strategic visions and anticipating on implementation is essential for achieving sustainable primary care transformation. By engaging in structured, collaborative, and participatory roadmap development, participants will gain actionable strategies to translate (national) primary care visions into effective implementation activities. By combining collective learning and identifying success factors, this workshop contributes to strengthening primary care and to effective bridging the gap between vision and action.

ID 2015- Sports Medicine in Primary Care: Essential Strategies for Professional and Elite Athletes

Sofica BISTRICEANU

Aphc, Wonca, Tg. Neamt, Roumanie

Context: Background: People must interact with one another to exchange products, as no one knows or produces everything. How they do that influences their equilibrium and, consequently, their personal, professional, and social lives. Aim: To highlight the effects of improper interactions on people's lives and how we can manage them.

Methods: The author conducted a qualitative study in the community from 2008 to 2025 on the effects of unsafe communication on people's lives and their management.

Originality: Findings Inappropriate communication negatively impacts all parties involved in collaborative work. Depending on

the magnitude of the unsafe interaction, time exposure, and the vulnerability of the intended recipient, their health could be affected more or less, leading to varied disorders, such as arterial hypertension, type 2 diabetes, dyslipidaemia, depression, and even brain haemorrhage and tumors. Their deteriorating health reduced their work efficiency and career prospects. Actions were taken Management of subsequently registered disorders included specific, personalized drug treatment, behaviour change information, interdisciplinary collaboration when necessary, and informative programs in the community for individual life improvement.

Lessons learned and future implications: Improper communication between individuals can worsen nervous, cardiovascular, endocrine, metabolic, or even cell-growth control in vulnerable individuals. Clinical outcomes can improve sooner or later, depending on the patient's involvement in collaborative care with providers, the progression of the disorder, and personal social and medical history.

Discussion: Impolite verbal and nonverbal communication disturbs human equilibrium, leading to varied illnesses, work inefficiency, increased healthcare costs, and decreased personal, professional, and social life and well-being. Informative programs are required to enhance people's lives.

Conclusion: Improper communication alters people's lives, including their health. Educational programs are necessary to enhance their quality of life.

(5) National Centre For Emergency Primary Health Care, Bergen, Norvège
(6) Aarhus University, Aarhus, Danemark

Context: Across Europe, urgent primary care services provide 24/7 or out-of-hours (OOH) care for non-life-threatening illness or injury needing urgent attention. These services, often staffed by General Practitioners (GPs) are vital in providing urgent care and in reducing clinically inappropriate use of emergency ambulance services, emergency departments and reducing preventable emergency hospital admissions. However, these services are under increasing pressure across Europe, due to rising demand and staff shortages, posing a threat to patient safety and the sustainability of these services. A network of researchers on OOH primary care, has made it their mission to address these problems by collaborating and sharing knowledge on key topics, including the organisation and use of OOH care, telephone triage and Point-Of-Care Testing (POCT).

Objectives: Exchange knowledge and experiences between countries to facilitate learning on key topics underlying sustainable OOH primary care: - Gain insight into organisational models of OOH care in relation with the use of these services using registry data - Discuss telephone triage models and how they facilitate equal access to OOH care - Discuss the role of POCT at OOH services and how they contribute to quality patient care

Teaching method and workshop: First, the current state of knowledge on the three key topics in OOH will be presented, based on ongoing network collaborations. Then, participants can join one of the three key topic discussion groups, guided by several statements aimed at cross border c

Expected outcomes: A better understanding of the current state of OOH care on key topics and possible directions for innovation across Europe to promote sustainable OOH care.

Conclusion: Current OOH GP care may not be sustainable, considering workforce issues and increasing patient numbers. Therefore, it is important to respond proactively to these issues. This may be achieved by learning from

each other's experiences and collaborating in areas with knowledge gaps. To this end, we need a better understanding of each other's (health care) context.

(2) Centre National Des Soins Palliatifs Et De La Fin De Vie ; Etablissements Jeanne Garnier, 116 Avenue Emile Zola, F-75015 Paris, France, Paris, France

Context: Effective communication about end-of-life (EoL) care is essential, as general practitioners (GPs) play a central role in initiating timely discussions and supporting patients throughout the illness trajectory. However, EoL conversations are often postponed, and significant social and territorial disparities persist in access to information and support. Low health literacy, particularly among vulnerable populations, further limits patients' understanding of diagnoses, treatment options, and their rights.

Objectives: This workshop aims to strengthen GPs' literacy on EoL issues and to enhance their ability to support patients and caregivers in contexts marked by complexity, uncertainty, and diverse needs. The learning objectives include: (1) improving understanding of patients' legal rights and public health policies regarding EoL care; (2) highlighting the essential role of family caregivers; (3) identifying strategies and tools to inform and support patients in precarious situations; and (4) promoting the co-construction and use of national resources dedicated to primary care professionals.

Teaching method and workshop: The workshop will be based on an online application accessible by QR code in order to participate in an interactive quiz based on three clinical situations of palliative support (including the issues of early discussions, designation of a trusted person,

Expected outcomes: Through shared examples and practical insights, participants will deepen their knowledge of EoL support, better understand available evidence-based resources, and strengthen their confidence in initiating and conducting anticipatory discussions adapted to

Conclusion: By consolidating their skills, general practitioners will be able to initiate essential exchanges earlier and support the early appropriation of the rights of people at the end of life, and palliative and end-of-life support adapted to each situation.

Tzu-Yi YU [(1)], Zu-Chun LIN [(2)]

(1) Tzu Chi University; Mennonite Christian Hospital, Hualien, Taïwan
(2) Tzu Chi University, Hualien, Taïwan

Context: Delirium is a common yet under-recognized complication in mechanically ventilated ICU patients, contributing to prolonged ventilation, restraint use, sleep disruption, and increased risk of mortality. This case involves a 51-year-old man with acute respiratory failure who developed CAM-ICU–positive delirium characterized by agitation and sleep–wake reversal. The nursing team implemented the ABCDEF ICU Liberation Bundle to mitigat risks.

Methods: The ABCDEF bundle consists of: A: Assess, Prevent, and Manage Pain: CPOT-guided analgesia (scores 3–4 → 0–1). B: Both SATs and SBTs: daily readiness testing for sedation interruption and ventilator weaning. C: Choice of Sedation: avoidance of benzodiazepines; titration to RASS −1 to 0 to maintain light, cooperative sedation. D: Delirium Assessment, Prevention, and Management: twice-daily CAM-ICU, reorientation, nighttime noise reduction, sleep promotion, and minimized psychoactive agents. E: Early Mobility: progression from passive ROM to active limb exercises and bed-

edge sitting, supporting oxygenation and muscle preservation. F: Family Engagement and Empowerment: structured involvement to enhance emotional stability, orientation, and communication. Daily outcomes included CAM-ICU, RASS, CPOT, restraint duration, sleep continuity, mobility progression, oxygenation stability, and emotional responsiveness.

Originality: This case demonstrates the full implementation of all six bundle components, illustrating how nursing-led coordination can operationalize physiologic, cognitive, environmental, and psychosocial interventions to achieve measurable improvements in a real ICU setting.

Lessons learned and future implications: Delirium improved rapidly (CAM-ICU Days 1–3 → negative by Day 5). Restraints decreased from bilateral to a single soft restraint by Day 10 and were removed post-extubation. Sleep consolidated from 3–4 nightly interruptions to 7–8 hours. Mobility progression stabilized oxygenation, preserved muscle strength, and supported extubation on Day 15. Family involvement enhanced emotional stability and communication. Future priorities include nighttime care protocols, structured family engagement, and digital checklists to strengthen adherence.

Discussion: Clinical outcomes aligned with evidence showing that multimodal delirium strategies shorten delirium duration, stabilize sedation, strengthen mobility, and increase patient participation in care.

Conclusion: The ABCDEF bundle effectively reduced delirium duration, minimized the use of restraints, restored sleep rhythms, and supported earlier cognitive and functional recovery. Nursing leadership was essential in coordinating interventions and sustaining ICU Liberation practices. Keywords: Delirium, Intensive Care Unit, Patient Care Bundles

Context: Glass ampoules provide stable medication storage, but their brittleness makes improper breaking techniques prone to uneven necks and sharp injuries. Up to 38% of nurses and nursing students report ampoule-related cuts, which may lead to bloodborne infection risk, psychological stress, financial burden, and medication contamination, affecting both healthcare workers and patients.

Objectives: To evaluate the effectiveness of an innovative ampoule-opening device in improving occupational safety during medication preparation.

Methods: This randomized controlled trial enrolled clinical nurses from a medical center. Participants were assigned to one of three opening methods—alcohol swab + bare hand, scissors, or an ampoule-opening device—and instructed to break 5 mL, 10 mL, and 20 mL ampoules in randomized order. Data were analyzed using SPSS 25, and general linear regression was used to compare breaking time, sharp-injury occurrence, and neck defects across methods.

Results: A total of 108 nurses participated (86.1% female; mean age 28.63 ± 6.4 years). Only one sharp injury occurred in the alcohol swab + bare-hand group. The ampoule-opening device achieved the shortest breaking time for 5 mL and 10 mL ampoules and was faster than the bare-hand method for 20 mL ampoules (all $P < .05$). Compared with the device, scissors produced 0.86, 1.31, and 1.64 more neck defects for 5 mL, 10 mL, and 20 mL ampoules (all $P < .05$). The bare-hand method created slightly more defects (0.06, 0.42, 0.39), though differences were not statistically significant.

Discussion: Although not all outcomes reached statistical significance, the device reduced breaking time and generated smoother neck surfaces, while also lowering the risk of sharp

injuries. The absence of cuts in other groups may reflect participants' increased caution and the controlled testing environment, which does not fully represent fast-paced clinical conditions. As an engineering control within the Hierarchy of Controls Framework, the device offers a practical strategy to enhance occupational safety and should be considered for use in clinical settings.

Conclusion: Limited observed effects may reflect insufficient training with the ampoule-opening device. Future research should include adequate training, compare performance across healthcare roles, and assess cost-effectiveness to support broader clinical adoption. Keywords: accidental injuries, engineering controls, occupational safety, safety equipment

ID 512- Strengthening primary care in Europe through collaborative action: vision XXX

Justin BONNICI

Primary Health Care, Valletta, Malte

Context: Polypharmacy increases in older persons and in multimorbid patients thus becoming prevalent in primary health care. While deprescribing offers a patient-centered, systematic approach to reducing potentially inappropriate medicines, implementation remains inconsistent based on clinical, systemic, and patient-level factors.

Objectives: The purpose of this literature review is to outline the enablers and barriers of deprescribing in primary care and, on the basis of current evidence, and identify successful solutions for implementation.

Methods: A review of the literature was performed utilising PubMed, Medline, Cochrane Library and Embase, as institutional databases. English publications between 2020 and mid-2025 were screened utilising predefined inclusion and exclusion criteria. The CASP framework was used to critically appraise 43 peer-reviewed articles. Data were synthesised thematically with arising patterns grouped into their own main themes and sub-themes.

Results: Dominant themes that occurred were prescriber confidence, patient refusal, time constraints, and lack of overt guidelines as key barriers.

Discussion: Enablers such as multidisciplinary collaboration, use of evidence-based deprescribing tools (e.g. STOPP/START, Beers Criteria), and patient engagement were reported across all settings. Implementation strategies varied between settings but the majority contained important pharmacist interventions, education programmes, and formal implementation protocols.

Conclusion: Deprescribing within primary care can be done and is necessary but requires multi-faceted interventions targeting individual prescribers, systems, and patients. To enhance uptake and sustainment, deprescribing has to be incorporated into routine care in combination with training, decision aids, and policy-level promotion.

ID 1436- Strengthening Rural Primary Care Through Clinical Champions and Micro-MDT Models to Reduce Inequalities Aligned With NHS, WHO and WONCA Priorities

Amit GIBORI, Hanny YESHUA

Clalit Health Services, Tel Aviv, Israël

Context: This report details the complex care of a 69-year-old retired nurse following a critical ST-Elevation Myocardial Infarction (STEMI), complicated by hemodynamic collapse and subsequent surgical and infectious complications. This case reflects the edge-group of healthcare professionals as patients, often experiencing problematic access to unbiased self-assessment and care acceptance.

Methods: The patient, a former nurse, demonstrated professional denial, minimizing her own symptoms and struggling to relinquish control, which led to significant emotional distress. The clinical course included a

successful but complex percutaneous coronary intervention, followed by a necessary vascular repair after ECMO decannulation, prolonged IV antibiotic therapy due to bacteremia and suspected endocarditis, and a persistent surgical wound infection requiring VAC therapy (Vacuum-Assisted Closure) The family physician provided comprehensive, integrated management: 1) Case Manager: Serving as the central hub coordinating specialized care (Cardiology, Vascular) and managing: secondary prevention, polypharmacy and chronic wound care in the community setting. 2) Psycho-Social: Addressing her professional identity crisis, supporting the patient through concurrent bereavement, and providing continuous emotional and psychological support, mitigating the impact of the critical events on the patient's well-being.

Originality: This case highlights the psychological burden when a medical professional transitions to patienthood, as clinical knowledge paradoxically becomes a barrier to recovery and trust. It also models the Family Doctor's essential role in transcending this barrier, providing holistic, longitudinal care continuity across acute, tertiary, and community settings, particularly following multiple complications.

Lessons learned and future implications: Future practice should integrate explicit communication strategies tailored for healthcare workers to ensure their recovery is not impeded by their professional identity.

Discussion: The challenges for medical professionals as patients - denial, self-diagnosis, and delayed care acceptance - are significant and exacerbate the patient's distress. This case confirms the family physician's vital role as the bio-psycho-social anchor. The family doctor's established, continuous relationship was the reliable mechanism used to bypass this cognitive and emotional barrier, facilitating essential coordination and acceptance.

Conclusion: This case confirms the Family Doctor's indispensable role in facilitating comprehensive recovery by integrating complex clinical management with crucial psychological and social support, ensuring care overcomes the patient's professional barriers.

(2) Landelijke Huisartsen Vereniging (lhv), Utrecht, Pays-Bas
(3) Ineen, Utrecht, Pays-Bas

Context: Demographic trends and systemic challenges pose threats to the continuity of primary care in XXX. To provide an effective response to these challenges, a shared vision for primary care is essential. The previous vision no longer fully reflected current challenges or emerging technological opportunities. Therefore, XXX, XXX, and XXX collaborated to create a new vision: XXX. General practitioners (GPs) in XXX constitute a heterogeneous group (including locum GPs, practice owners and GPs on salary), with diverse professional expectations. To ensure successful implementation, broad support from all XXX general practitioners was crucial. Therefore, we included GPs in all phases of the process.

Methods: We used several established scientific methods to formulate the vision bottom-up, including a participatory design that combined qualitative and consensus-driven methodologies. Core values for general practice, as well as a review of relevant literature served as a baseline. We used focus groups and expert interviews to explore perspectives on the future of primary care. With these data, we developed a draft vision. Key components of this draft were validated through a nationwide survey among GPs. During this process, a large group of representatives of GPs and an advisory panel provided feedback at various times. The process contributed to broad consensus, which

was reflected in widespread support during the final endorsement.

Originality: The vision was co-created through consensus-driven dialogue, integrating diverse perspectives. This bottom-up method facilitated a shared vision, with broad support, from the heterogeneous group of XXX GPs.

Lessons learned and future implications: The collaborative development of this vision showed that structured, inclusive participation of GPs strengthens broad support. Such an approach is essential in heterogeneous contexts.

Discussion: XXX primary care has a longstanding tradition of joint vision development by XXX, XXX and XXX. These organizations represent nearly all GPs and regional bodies. This structure enables broad support for shared strategic visions.

Conclusion: The co-creation of this vision, through a bottom-up approach involving GPs in every aspect, enhances "fraternity" and support, and therefore future sustainable implementation.

Sungrok JEONG [(1)] , Yuna CHOI [(2)]

(1) Ppeum Global Myeongdong, Seoul, Corée (République de)
(2) Seoul Medical Center, Seoul, Corée (République de)

Context: Age-related fertility decline increasingly affects couples worldwide. As a 43-year-old family physician with no prior running experience, I faced repeated assisted reproductive technology (ART) failures with my wife. This personal struggle prompted reflection on whether accessible lifestyle strategies—particularly aerobic activity that even complete beginners can adopt—may support natural conception in middle-aged couples.

Methods: In 2024, my wife and I underwent three cycles of intrauterine insemination (IUI): one failed to implant and two ended in early loss. With concerns about age-related decline, we began a shared running routine. As a complete novice, I started on June 9th, 2025 with 1-minute treadmill runs at 10 km/h followed by 2–3 minutes of walking, gradually increasing intervals weekly. Over several weeks, I progressed to running 10 continuous minutes and more than 5 km outdoors at a pace of 6'30"/km. My wife, also a beginner, followed a similar gradual protocol at 8 km/h initial bouts, eventually running ~3 km outdoors at 7'30"/km. This routine improved vitality and sleep regularity. Remarkably, my wife conceived naturally in August 2025—two months after beginning the program.

Originality: This case uniquely illustrates how a middle-aged couple with no prior running experience may achieve natural conception after repeated ART failures through progressive, accessible aerobic training. It highlights a realistic "zero-to-hero" pathway demonstrating that individuals of any age, body size, or fitness level can safely begin running using short bouts, slow pacing, and gradual workload increases.

Lessons learned and future implications: Structured aerobic activity may serve as a low-cost, equitable adjunct during fertility counseling for middle-aged couples. Integrating modifiable couple-level lifestyle strategies into primary care may enhance patient-centered fertility support.

Discussion: Improvements in sleep, metabolic health, and shared behavioral changes likely created a favorable biological environment for conception. The synergistic effect of both partners engaging in progressive exercise may have amplified these benefits beyond what prior ART attempts achieved.

Conclusion: Regular running initiated by two previously sedentary adults was temporally associated with natural conception following ART failures. Aerobic exercise may represent an accessible, evidence-informed element of infertility counseling—feasible for individuals of all ages, body sizes, and fitness backgrounds.

Context: Secure fixation of endotracheal tubes (ETT), nasogastric tubes (NGT), and oral bite blocks is essential in both adult and pediatric intensive care units (ICUs). Conventional adhesive-based methods often cause skin injury, unstable positioning, repeated re-fixation, and increased workload. Existing commercial devices rarely integrate NGT or bite block support, which contributes to fragmented workflows and a higher risk of dislodgement.

Objectives: To evaluate the usability and clinical applicability of an innovative three-in-one fixation and adjustment device that simultaneously secures ETT, NGT, and the bite block.

Methods: Guided by design thinking principles, the device was co-developed by nursing faculty and students to address key clinical pain points. A usability study was conducted with 20 participants in a laboratory simulation. Participants completed a four-item usability assessment, and qualitative feedback was analyzed thematically.

Results: Participants included clinical nurses (70%), nursing faculty (15%), and nursing students (15%). They reported improved tube stability, reduced unplanned displacement, and decreased reliance on adhesive tape, particularly beneficial for pediatric patients with smaller facial contours and sensitive skin. The adjustable structure enhanced fixation symmetry and reduced lateral shifting, while integrated bite block positioning offered greater precision than traditional methods. Workflow advantages included faster setup, easier repositioning, and reduced material use. Suggested refinements included improved cushioning, longer straps for larger facial profiles, and increased adaptability. The device has been submitted for patent protection (Taiwan Patent Application No. 114116XXX) and has received multiple national and international innovation awards.

Discussion: User feedback aligned closely with the five core design principles. The three-tube modular integration addressed workflow fragmentation and reduced the need for repeated taping. The four-point adjustable frame improved fit and stability, as noted in comments about decreased lateral shifting. The extended cushioned bite block enhanced comfort and oral protection, especially in pediatric care. The modular base-and-attachment system increased flexibility and reduced waste. Philtrum-centered anchoring with four-point pressure distribution reflected users' appreciation for improved comfort and reduced pressure risk.

Conclusion: This three-in-one fixation device demonstrates strong usability, clinical relevance, and scalability across ICU settings. Further real-world testing and refinement will support the broader adoption of this approach.

Jiho CHOI, Zee Hae BANG

Department Of Family Medicine, Inha University College Of Medicine, Incheon, Corée (République de)

Context: The prevalence of hyperuricemia have increased over the past few decades. Hyperuricemia is considered to be responsible for the increased risk of hypertension, type 2 diabetes mellitus, chronic renal disease, and cardiovascular disease. Health-related quality of life (HRQoL) is increasingly used as an outcome in clinical trials, effectiveness research, and research on quality of care.

Objectives: We aimed to analyze the association between hyperuricemia and HRQoL in Korean adults older than 19 years.

Methods: We included 2,376 men and 2,593 women who participated in the Korea National Health and Nutrition Examination Survey from 2016 to 2017. Hyperuricemia was defined as serum uric acid 7mg/dL. The Euro quality of life-5 dimension (EQ-5D) instrument was used as the measure of HRQoL. A multiple logistic regression analysis was performed to examine the association between Hyperuricemia and HRQoL.

Results: The EQ-5D index score in hyperuricemia group was significantly lower than normal group. After adjusting for multiple covariates, the odds ratios (95% confidence intervals) for problems with mobility were 1.46 in men and 1.33 in women; however, the difference was not statistically significant for women.

Discussion: This study is meaningful in that hyperuricemia affects health-related quality of life not only in the elderly population but also in the young population in their 20s and 30s, suggesting that they need proper management of hyperuricemia.

Conclusion: Hyperuricemia was associated with poor quality of life. It is important to control serum uric acid levels to improve HQoL.

ID 1222- Subtle Clues, Serious Exposure: Chronic Lead Toxicity Identified in a Family Medicine Setting

Young Chan CHO, Chan Hee SONG

Yeouido St.mary's Hospital, Korea, Seoul, Corée (République de)

Context: Growing concern about mental health disorders has become a major public issue in South Korea, driven by sociocultural and economic pressures and reflected in the nation’s highest suicide rate among OECD countries. Obstructive sleep apnea (OSA), a prevalent sleep-related breathing disorder, may exacerbate psychological distress by disrupting sleep quality.

Objectives: This study aimed to examine the relationship between OSA risk, as measured by STOP-BANG, and mental health outcomes, including anxiety and depressive symptoms, using nationwide data from the 2021 Korea National Health and Nutrition Examination Survey (KNHANES).

Methods: A total of 3,910 adults aged ≥40 years (1,706 men and 2,204 women) from

KNHANES 2021 were analyzed. Participants completed the STOP-BANG questionnaire to assess OSA risk and the Generalized Anxiety Disorder-7 (GAD-7) scale to measure anxiety symptoms. Demographic, lifestyle, and clinical covariates were included, such as age, BMI, socioeconomic factors, comorbidities, and perceived stress. Logistic regression analyses were performed to examine associations between STOP-BANG scores and mental health outcomes, adjusted for potential confounders.

Results: Men exhibited higher BMI and cardiometabolic comorbidities, while women had higher rates of depressive symptoms and lower socioeconomic status ($p<0.05$). Higher STOP-BANG scores were significantly associated with increased perceived stress (OR 1.37, 95% CI 1.22–1.54), greater GAD-7 scores (OR 1.08, 95% CI 1.05–1.11), and higher odds of experiencing a depressive mood lasting more than two weeks (OR 1.94, 95% CI 1.54–2.45). Sex-specific analyses revealed that certain OSA risk components (e.g., snoring, tiredness, observed apnea) were more strongly associated with mental health outcomes in one gender than the other.

Discussion: Our findings underscore the complex interplay between sleep apnea risk factors and mental health, highlighting the need for gender-specific approaches in managing patients with potential OSA. The differential impact of OSA risk factors on mental health outcomes between genders emphasizes the importance of considering gender in both the screening and treatment of sleep apnea and associated mental health conditions.

Conclusion: Higher OSA risk assessed by STOP-BANG was significantly associated with anxiety, stress, and depressive symptoms, independent of major confounders. The findings underscore the need for gender-specific strategies and early screening for OSA as part of comprehensive mental health assessment.

(1) Unsw, Sydney, Nsw, Australie
(2) Usyd, Sydney, Nsw, Australie

Context: Context: Long-term use of prescribed opioids for the management of chronic pain in the primary care setting in Australia is associated with opioid dependence. This is often undiagnosed and untreated, with attendant harms.

Objectives: Objectives: This research sought to analyse Australian GPs' intention to diagnose and manage opioid dependence in their patients' prescribed opioids for chronic pain and understand how this may have changed over time.

Methods: Methods: This longitudinal theory-based qualitative research used repeated semi-structured interviews with 24 GPs working in New South Wales, Australia. We analysed GP intention to diagnose and manage opioid dependence in their patients' prescribed opioids for the management of chronic pain through the three factors of the Theory of Planned Behaviour: attitude, social norms and behavioural controls. We also assessed the impact on intention due to time, programs, policies, and other incentives that occurred between 2021 and 2023.

Results: Results: Theory of Planned Behaviour factors affected GPs' engagement in opioid dependence diagnosis and management. Experience of fruitful conversations with patients regarding opioids, pain and risk strengthened positive attitudes. Patients expressing a desire to change opioid use due to opioid risk concerns and colleagues who diagnosed and managed opioid dependence built positive social norms for participants. Education, increased skills, real-time prescription monitoring tools, changes to government funding and approval of medications, collegial support and workplace increased positive behavioural controls. Difficult, futile conversations with patients,

adverse regulatory experiences, isolation, and perceived imperative to shift care to specific monitored medicine programs decreased intention. Covid had an impact, and over the study period, many participants chose to decrease or cease general practice.

Discussion: Discussion: Positive attitudes, social norms and behavioural controls may increase GPs' intention to diagnose and manage opioid dependence in their chronic pain patients.

Conclusion: Conclusions: Programs and initiatives that consider and build positive attitudes, social norms and behavioural controls may assist GPs to better manage opioid use, including deprescribing or opioid dependence treatment in their chronic pain patients, potentially with better treatment outcomes. Current funding limitations in Australian general practice must be addressed.

ID 2113- Supporting Patient Wellbeing Through Digital Self-Management Tools: Scalable Approaches for Global Primary Care

A-Sol KIM, Ji-Eun SONG

Department Of Family Medicine, School Of Medicine, Kyungpook National University, Daegu, Corée (République de)

Context: Seborrheic dermatitis is a chronic inflammatory skin disorder affecting the scalp, face, and upper trunk. Evidence suggests a link between seborrheic dermatitis and systemic metabolic abnormalities, especially among individuals with metabolic syndrome, a condition involving central obesity, dyslipidemia, hypertension, and impaired glucose metabolism. However, specific clinical and biochemical predictors of seborrheic dermatitis in this population remain unclear.

Objectives: To identify clinical and biochemical predictors of seborrheic dermatitis and to estimate individual risk among people with metabolic syndrome using a machine learning approach applied to real-world clinical data.

Methods: We conducted a retrospective observational study using electronic medical records from a tertiary hospital. Adults who visited the hospital between January 2018 and December 2024 and met the National Cholesterol Education Program Adult Treatment Panel III (NCEP-ATP III) criteria for metabolic syndrome were included. Seborrheic dermatitis was identified using International Classification of Diseases, 10th Revision (ICD-10) codes and verified through clinical notes; patients with non-specific skin symptoms were excluded unless seborrheic dermatitis was clearly documented. Features included age, sex, body mass index (BMI), waist circumference, triglyceride-to-high-density lipoprotein (HDL) ratio, fasting glucose, glycated hemoglobin (HbA1c), smoking, alcohol use, and comorbidities. A gradient boosting model (extreme gradient boosting, XGBoost) was trained to predict seborrheic dermatitis, and performance was evaluated using five-fold cross-validation.

Results: Among 446 patients with metabolic syndrome, 53 (11.9%) had seborrheic dermatitis. The machine learning model achieved an area under the receiver operating characteristic curve (AUC) of 0.78, accuracy of 74.4%, precision of 61.7%, recall of 66.0%, and F1-score of 63.8%. Shapley Additive Explanations (SHAP) indicated that triglyceride-to-HDL ratio, HbA1c, BMI, and smoking status were the most influential predictors of seborrheic dermatitis risk.

Discussion: This electronic medical record–based machine learning study highlights the role of metabolic imbalance and lifestyle factors in seborrheic dermatitis among patients with metabolic syndrome.

Conclusion: Predictive tools based on routinely collected clinical data may support early identification and risk stratification of seborrheic dermatitis in primary care, but prospective validation in diverse settings is needed.

ID 1984- Suspected Digoxin Toxicity Due to Polypharmacy in an Older Adult: A Case Report from Primary Care

Catherine KUO, Linu JOSEPH

Northeast Georgia Medical Center, Gainesville, États-Unis

Context: Women's health perceptions shape preventive care behavior and reflect the sociocultural environments in which they live. However, limited research exists comparing how women in developed and developing countries access and trust medical information.

Objectives: The objective is to characterize differences in trusted sources of medical information and community health perception among women in XXX (developed community) and YYY (developing community) to inform equitable region-specific patient education strategies.

Methods: A prospective cross-sectional survey was administered to women ≥18 years old in a primary care clinic in XXX and community outreach clinics in YYY. Survey domains assessed personal and community health perception and trusted sources of medical information. Responses were analyzed using descriptive statistics and logistic regression.

Results: Among 119 participants (XXX = 51; YYY = 64), healthcare providers were the most used and trusted source of medical information in both locations, followed by family and friends. Compared to women in YYY, women in XXX expressed a greater trust in internet (73% v. 17%, p<0.001) and social media-based platforms (37% v 7.8%). Compared to women in XXX, women in YYY commonly trusted religious institutions for health information (70% v. 49%, p= 0.03). Older women in XXX were more likely to view their community as healthy (OR 0.967, 95% CI 0.932–0.998, p=0.027), while there was insufficient evidence to confidently delineate the relationship between community health perception and age in YYY (OR 1.028, 95% CI 0.991 to 1.079, p=0.085).

Discussion: Differences in trusted sources reflect the sociocultural and technological infrastructures of each setting. Reliance on internet-based resources among XXX participants aligns with high digital access in developed countries, while YYY participants' trust in religious institutions highlights the central role of community-based networks. The more positive community health perceptions reported by older women in XXX may reflect greater availability of age-friendly health services in developed regions.

Conclusion: Although healthcare providers are universally trusted, digital strategies are utilized more by XXX and community-based approaches are more meaningful in YYY. Additionally, targeted initiatives for older women in YYY may help address disparities in perceived community health. Tailoring patient education to local information ecosystems may strengthen patient engagement across both regions.

ID 1150- Synergistic Role of Vitamins D and K in Bone and Cardiovascular Health: A Literature Review with Implications for European General Practice

Tzu Lin YEH

Hsinchu Mackay Memorial Hospital, Hsinchu City, Taïwan

Context: Body mass index (BMI) has a J-curve relationship with mortality, but the physiological mechanisms underlying its effects are complex and paradoxical. Understanding whether early cardiac structural changes, specifically left ventricular mass (LVM), modulate the relationship between BMI and all-cause mortality is crucial for public health evaluation.

Objectives: To investigate the mediating role of LVM, in the relationship between BMI and all-cause mortality.

Methods: The Chin-Shan Community Cardiovascular Cohort (CCCC) study was a prospective cohort consisting of participants from one community in Taiwan in 1990-1991. The inclusion criteria were adult participants in CCCC with complete data for BMI, and LVM from echocardiography measurements. Deaths were ascertained by hospital-based medical

records and official death registry database. Cox regression models were applied to determine the association between BMI, LVM and all-cause mortality. The mediation was quantified using the Delta Method and confirmed via the Bootstrapping method (N=1,000 replicates).

Results: A total of 2,918 participants with the mean (standard deviation) age 54.2 (11.8) years and 54.1% women were included. Their mean (standard deviation) BMI was 23.51 (3.36) kg/m^2. In the median follow period was 22.4 years, 984 deaths developed. BMI significantly decrease the all cause-mortality risk, with the hazard ratio [HR]= 0.946 and 95% confidence interval [CI], 0.924-0.969. Meanwhile, LVM significantly increase the all cause-mortality risk, the HR (95 % CI) was 1.004 (1.003-1.005). The analysis revealed a statistically significant suppression mediation: the total effect of BMI on the hazard of death was estimated to be -0.021 [-0.042, -0.0004]. However, a significant positive indirect effect 0.0271 [0.011, 0.043], suggests that LVM mediates the association.

Discussion: This suppression effect highlights the "obesity paradox" in that BMI's overall benefit is actively counteracted by its detrimental effect on LVM. Public health efforts should consider LVM reduction alongside weight management.

Conclusion: The study indicates that the protective direct effect of BMI is suppressed by an increased risk of death mediated through higher LVM.

Rafael RÍOS BERNABÉ, Natalia LATES PROFIR, Rafael RÍOS DE MOYA-ANGELER, Carmen FRONTELA SASETA, Alfonso RÍOS BERNABÉ, Rubén LÓPEZ NICOLÁS

Imib, Lorca, Espagne

Context: Sustained exposure to dietary patterns with a high content of ultra-processed foods has been linked to a significant increase in the risk of developing various metabolic disorders, including metabolic dysfunction-associated steatotic liver disease (MASLD). The growing global prevalence of MASLD highlights the urgent need to elucidate its pathogenic mechanisms more precisely, since, due to the different pathways involved, there are currently no recognised effective therapies, reinforcing the strategic importance of identifying new molecular targets and specific therapeutic approaches. The HepG2 cell line is a relevant and effective in vitro model for studying hepatic steatosis. Some plant extracts have demonstrated hepatoprotective activity through the modulation of metabolic pathways that suppress lipid accumulation in the liver. However, the available knowledge on additives used in the formulation of ultra-processed foods (UPF) remains limited.

Objectives: The aim of this research was to analyse the effect of different food additives and plant extracts on the establishment and evolution of MASLD in HepG2 cells.

Methods: The human liver cell line HepG2 was used as an in vitro model. The different food compounds were evaluated at a concentration of 1% for 48 hours in EMEM medium. After 24 hours of exposure, palmitic acid was added at a concentration of 200 mM to induce steatosis. Subsequently, Oil Red O staining was performed to quantify intracellular lipid accumulation.

Results: The results indicated that cells exposed to plant extracts (curcumin, hesperidin, and lycopene) showed minimal intracellular lipid accumulation. In contrast, treatment with the food additive tartrazine was associated with a marked increase in the size of cytoplasmic lipid droplets.

Discussion: The different behaviour between plant extracts and tartrazine suggests that these compounds act through opposing cellular mechanisms in the regulation of lipid content. This raises the need to investigate further how certain food additives could contribute to metabolic imbalances in the liver.

Conclusion: Plant extracts could exert a beneficial modulatory effect by attenuating the processes that lead to the induction of

hepatocellular steatosis. Conversely, various food additives show signs of promoting intracellular lipid accumulation, thus favouring the onset of steatosis compatible with the early stages of MASLD.

ID 415- Systematic review of barriers, facilitators and recommendation rates of physical activity and weight management apps among primary care healthcare professionals

Yosser GAAYEB

Family Medecin, Nabeul, Tunisie

Context: The benefits of vitamin K antagonists (VKAs) have been widely demonstrated across numerous indications. Although their efficacy is well established, these drugs may lead to various complications, among which hemorrhagic events are the most frequent and severe. Acute gastrointestinal bleeding is one of the main presentations of VKA overdose.

Objectives: Identify predictive factors of mortality in patients admitted to the emergency department for upper gastrointestinal bleeding associated with VKA overdose.

Methods: We conducted a prospective, single-center study over a one-year period (January 2023–January 2024). All patients admitted to the emergency department for upper gastrointestinal bleeding with documented VKA overdose were included. Epidemiological, clinical, biological, endoscopic, and therapeutic data were collected. A multivariate analysis was performed to determine independent predictors of in-hospital mortality.

Results: A total of 43 patients were included (mean age 71 ± 14 years; sex ratio 1.15). All received Sintrom for atrial fibrillation, valve replacement, deep vein thrombosis, or pulmonary embolism. Main comorbidities were hypertension, diabetes, coronary artery disease, and dyslipidemia. Presenting symptoms were hematemesis, melena, general deterioration, and abdominal pain. Hemodynamic instability at admission: SBP < 90 mmHg in 27%, DBP < 50 mmHg in 23%, HR > 100 bpm in 48%. Hemoglobin < 7 g/dL in 50%. Mean INR 11 ± 7, with 50% > 10. Endoscopy was performed in 60% of cases; peptic ulcer disease in 21%. In-hospital mortality was 14%. Univariate predictors of mortality: Blatchford score ≥ 14, norepinephrine use, urea > 16 mmol/L. Multivariate analysis: only Blatchford score ≥ 14 remained significant.

Discussion: Several scoring systems have been developed to assess the prognosis of this condition. The Blatchford score was found to be more predictive of clinical risk compared with the initial Rockall score, as well as more accurate in identifying the need for blood transfusion.

Conclusion: Our study demonstrated that clinical assessment and simple biological parameters provide easily identifiable predictors of mortality at admission in patients presenting with upper gastrointestinal bleeding related to VKA overdose.

Context: The XXX supports global primary care collaboration through education, research, and exchange opportunities for GP trainees and First5 GPs. With more than a decade of XXX-facilitated exchanges, the XXX Programme provides structured, short-term placements that strengthen professional development and cross-cultural understanding. Established pathways such as the Hippokrates Exchange (two-week European placements), Family Medicine 360 (FM360; global exchanges up to four weeks), specific country exchanges, and Conference Exchange initiatives enable participants to gain experiential learning aligned with XXX curriculum domains, including equality, diversity and inclusion, leadership,

and working effectively within organisations and systems of care.

Objectives: The workshop aims to familiarise participants with the purpose, structure, and application processes of the Exchange Programmes and to demonstrate how international exchanges enhance clinical insight, reflective practice, and leadership growth. Participants will explore how exchanges broaden global networks, enrich GP training, and support portfolio development or quality improvement activities.

Teaching method and workshop: The session will begin with an overview presentation outlining each exchange programme, key learning objectives, application and hosting processes, and examples of clinical or conference-linked activities. Following this, participants will join facilitate

Expected outcomes: By the end of the workshop, participants will be able to describe the range and purpose of XXX Exchange Programmes and articulate how these experiences contribute to personal and professional development. They will be able to reflect on competencies relat

Conclusion: This interactive session highlights how XXX Exchanges provide transformative opportunities for early-career GPs, fostering global collaboration, revitalising professional enthusiasm, and equipping participants with skills that enhance patient care and strengthen primary care systems internationally.

ID 1925- Teaching of Core Values in General Practice/Family Medicine – why and how?

Hugo FIGONI, Kim BONELLO, Sarah ROBERT, Candice ESTELLA

Sorbonne Université, Paris, France

Context: The use of generic drugs has been encouraged worldwide for several decades. Although increasing, their use in France remains limited in international comparisons. In the literature, among the factors associated with their use, several are linked to the prescriber, including their specialty. To our knowledge, this association has never been studied in France.

Objectives: The use of generic drugs has been encouraged worldwide for several decades. Although increasing, their use in France remains limited in international comparisons. In the literature, among the factors associated with their use, several are linked to the prescriber, including their specialty. To our knowledge, this association has never been studied in France.

Methods: We used a sample of an open available semi-aggregated database from the 2019 French health insurance system database. We compared with logistic regression models GPs to all other specialities combined, then GPs to the 19 other specialties taken individually, only on the substitutable drugs they prescribe in common.

Results: We used a sample of an open available semi-aggregated database from the 2019 French health insurance system database. We compared with logistic regression models GPs to all other specialities combined, then GPs to the 19 other specialties taken individually, only on the substitutable drugs they prescribe in common.

Discussion: To our knowledge, this study is the first in the French context to investigate the prescriber's specialty as a factor influencing generic dispensing, based on exhaustive community pharmacy dispensing data. Since we did not have access to the content of the prescriptions, we were unable to evaluate at which point in the drug use chain the difference occurred.

Conclusion: To our knowledge, this study is the first in the French context to investigate the prescriber's specialty as a factor influencing generic dispensing, based on exhaustive community pharmacy dispensing data. Since we did not have access to the content of the prescriptions, we were unable to evaluate at which point in the drug use chain the difference occurred.

(1) University Medical Center Utrecht, Utrecht, Pays-Bas
(2) Amsterdam University Medical Center, Amsterdam, Pays-Bas

Context: Elevated nighttime blood pressure is a well-established predictor of cardiovascular disease. While 24 hour ambulatory blood pressure monitoring (ABPM) from the upper arm is the standard for nocturnal blood pressure assessment, wrist-type home blood pressure monitoring (HBPM) offers potential advantages in convenience, yet its usability and impact on sleep quality remain underexplored.

Objectives: To compare the usability and impact on sleep quality of a wrist-type HBPM device and conventional upper-arm 24 hour ABPM device.

Methods: In this randomized crossover study, 60 community-dwelling individuals (50-80 years) from the RED-LRGP trial underwent wrist-type HBPM (Omron HEM-9601T) and upper-arm ABPM. HBPM included three nocturnal readings per night (4 hours after bedtime, at 02:00, and 04:00 hour) for five nights, and morning and evening daytime readings on these same days. ABPM included single day-and-night measurements with cuff inflations every hour. Participants completed the System Usability Scale (SUS) and visual analogue scale (VAS) for sleep quality after each device. Linear mixed-effects models were used to compare usability (SUS) and sleep quality (VAS) between devices.

Results: Sixty participants (mean age 58 years, 57% female, 23% hypertensive) completed questionnaires. HBPM showed higher usability (SUS 71.9 vs. 52.4; $p<0.0001$) and better sleep quality (VAS 74.6 vs. 58.9; $p<0.0001$) than ABPM. Repeated nightly HBPM captured night-to-night variability, detecting nocturnal hypertension in 27% to 39% of participants versus 26% by single-night ABPM, and non-dippers in 7% to 14% versus 25% by ABPM. Sixteen participants without obesity, hypertension or other relevant comorbidities were classified as HBPM non-dippers on one or more nights.

Discussion: This study may be valuable for guiding clinical applications of wrist-type HBPM as a patient-friendly approach for characterizing nocturnal BP patterns.

Conclusion: Wrist-type HBPM for five days and nights improves usability and preserves sleep quality compared with conventional, single day-and-night upper-arm ABPM. This furthermore enables repeated nocturnal measurements to capture night-to-night BP variability and supporting its use as a practical, user-friendly tool for home-based nocturnal BP monitoring.

(1) Semfyc, Camfic, Barcelona, Espagne
(2) Institut Català De La Salut, Bagà, Espagne
(3) Institut Català De La Salut, Guardiola De Berguedà, Espagne

Context: Chronic tophaceous gout has become uncommon in high-income countries due to improved diagnostics and effective urate-lowering therapies. However, its persistence in rural and geographically isolated communities reveals underlying inequities in access to healthcare services. These disparities, shaped by distance, limited local resources, and cultural or occupational constraints, continue to influence disease progression and management, even within universal healthcare systems.

Methods: We present a descriptive case report of a 88-year-old farmer from XXX, a rural village in the XXX, who attended a routine primary

care visit. Clinical data and pictures were collected with his explicit consent and through medical record review and physical examination, focusing on disease history and life habits. Contextual factors such as occupational demands, geographic barriers, and continuity of care were analyzed to understand contributors to the patient's advanced gout presentation.

Originality: This case highlights a condition traditionally associated with inadequate or delayed care, now resurfacing in a rural European context where universal health coverage ostensibly ensures equity. The report offers an integrated perspective that connects clinical findings with structural determinants of health, emphasizing how modern inequities drive the persistence of advanced diseases in specific territories.

Lessons learned and future implications: The case underscores the need for strategies that reinforce continuity of care in rural primary care settings, including improved access to laboratory testing, flexible monitoring pathways, and community-adapted follow-up models. Future initiatives should focus on territorial equity, telemedicine integration, and workforce reinforcement to ensure that chronic disease management is not conditioned by geography.

Discussion: The patient's chronic tophaceous gout, despite being on urate-lowering therapy, reflects long-standing gaps in monitoring and follow-up. Structural barriers, including the scarcity of local laboratory services, limited specialist access, and demanding agricultural work schedules, likely contributed to disease progression. This case illustrates how rurality intersects with health system limitations to produce advanced clinical presentations, challenging assumptions about the effectiveness of universal healthcare in eliminating inequities.

Conclusion: This case demonstrates that chronic diseases like tophaceous gout persists where structural inequities remain unaddressed. Primary care clinicians in rural settings play a critical role in identifying these gaps and advocating for resources and policies that ensure consistent, person-centered management across all territories.

ID 2180- Technical visits across Brazil's health care networks: a practice based reflection for undergraduate medical training

Sébastien BRUEL, Maëlys TIZGHAT, Dragos-Paul HAGIU

Department Of General Practice, Saint Etienne, France

Context: Point-of-care ultrasound (POCUS) is increasingly used in general practice, yet formal training during GP residency remains limited in many countries. Since 2022, the Department of General Medicine at XXX (France) has developed a structured ultrasound training program combining instruction from experts and training provided by GP trained in ultrasound to promote the long-term integration of POCUS into primary care.

Objectives: To describe the implementation of an introductory ultrasound course for GP residents and to evaluate its short-term impact on residents' satisfaction and motivation to pursue further training.

Methods: We conducted a pre–post evaluation among GP residents attending an introductory POCUS course at XXX during the 2024–2025 academic year. The course was delivered by a recognised ultrasound expert or training provided by GP trained in ultrasound, and covered basic image interpretation, probe handling, spatial orientation and standard ultrasound views. Residents completed self-administered questionnaires before and immediately after the course assessing: overall satisfaction (post only), perceived usefulness of the training self-reported confidence in basic ultrasound skills, perceived needs for further training.

Results: A total of 88 residents completed the pre-course questionnaire and 82 completed the post-course questionnaire. Most respondents had already used an ultrasound machine (77/88; 87.5%), but only 10.2% (9/88) reported having previously received any

ultrasound training. Prior use mainly occurred during rotations in the emergency department (n=48), gynecology department (n=13) and general practice (n=10). Satisfaction with the course was very high: 78/82 (95.1%) reported being “very satisfied” and 4/82 “rather satisfied”. Almost all participants (81/82; 98.8%) stated that the course met or exceeded their expectations. One participant expressed a desire for more hands-on practice. All respondents indicated that they would recommend the course to a colleague. Residents unanimously expressed interest in further ultrasound training, and all agreed that ultrasound education has a place within the third cycle of medical studies in general practice.

Discussion: This faculty-based introductory POCUS course for GP residents was very well received. Combining expert-led teaching and the involvement of trained GP supervisors appears to be a promising strategy for integrating POCUS into general practice training.

Conclusion: Further evaluations will explore its longer-term impact and the development of additional advanced modules.

Context: Cutaneous leishmaniasis remains endemic in several rural areas of Costa Rica, disproportionately affecting Ngäbe-Buglé indigenous children. Environmental exposure to sandfly vectors, mobility across forested zones, and housing conditions increase infection risk. Limited access to healthcare and delayed diagnostic opportunities often prolong disease evolution. During a clinical rotation in San Vito de Coto Brus, several Ngäbe-Buglé children presented with cutaneous lesions compatible with leishmaniasis. These cases, supported by photographic documentation, illustrate the ongoing burden of this neglected tropical disease in structurally vulnerable communities.

Methods: This visual case series draws on clinical encounters from primary care visits and community outreach in Ngäbe-Buglé settlements near San Vito. Data collection focused on physical examination and photographic documentation of lesion characteristics, including morphology, size, and anatomic distribution. Contextual variables such as exposure patterns, living environment, and access to care were also recorded to complement the visual assessment.

Originality: Visual documentation of cutaneous leishmaniasis in Ngäbe-Buglé children is rarely available, despite the community’s high exposure and structural vulnerability. By integrating clinical photography with field-based observations, this poster offers a clear and educational representation of lesion patterns encountered in a real rural setting. The combination of dermatologic images and contextual information highlights how environmental and social factors shape presentation, recognition, and access to care in indigenous pediatric populations.

Lessons learned and future implications: The cases highlight the importance of visual recognition for early diagnosis in resource-limited settings. Strengthening local diagnostic capacity, ensuring consistent availability of antileishmanial treatment, and reinforcing culturally adapted community outreach may reduce delays and prevent complications. Future strategies should incorporate telemedicine support and collaboration with indigenous leaders to promote sustainable public health interventions.

Discussion: The photographic cases reveal how environmental exposure, socioeconomic barriers, and long travel distances to healthcare centers contribute to advanced or persistent presentations. Visual documentation underscores classic ulcerative lesions and reinforces the role of frontline primary care in early recognition, even when laboratory

confirmation is limited. Addressing structural inequities remains essential to improving outcomes.

Conclusion: Cutaneous leishmaniasis continues to reflect structural vulnerability among Ngäbe-Buglé children in southern Costa Rica. Visual case documentation from primary care provides a powerful tool for clinical education, advocacy, and the development of territory-sensitive health strategies.

ID 1476- Telemonitoring in primary healthcare units: a new tool to improve access and communication

Manon CHEVENNEMENT, Jean-Pierre LEBEAU

Department Of General Practice, University Of Tours, Tours, France

Context: Although lipedema might affect 11% of women in the world, it remains underdiagnosed, often confused with lymphedema or obesity. Although several countries have established national guidelines for the diagnosis and management of lipedema, there are none in France.

Objectives: The objective was to describe the clinical pathway of these women in France.

Methods: We broadcasted a questionnaire among patients on symptoms and treatment, a descriptive analysis was carried out for each of them, followed by a comparative analysis. We then conducted semi-directed interviews following a guide inspired by the MINI (McGill Illness Narrative Interview) with voluntary patients for them to express their feelings and their experience of the disease and their care pathway. The analysis was conducted according to an explanatory paradigm inspire by grounded theory.

Results: 1552 patients were included for the quantitative study. The mean medical wandering was 19 years. 82% of the patients had already consulted for their symptoms but only 62% had obtained a diagnosis of lipedema, mainly by an angiologist, despite having consulted their GP among a large number of healthcare professionals. Most of the operated patients went outside of France. In the 4 interviews, patients expressed great isolation, reinforced by social and medical stigma because of the lack of knowledge around their pathology and confusion with obesity. The disease, its limitations and the difficult clinical pathway had fueled feelings of depression, injustice and anger.

Discussion: These data sustain other european studies (from Germany, UK, Sweden, Netherlands), showing a medical wandering of 15+ years and the need to consult at least 3 doctors to get a diagnosis. Like in other countries, women with lipedema in France are feeling isolated, angry and not heard nor recognized in their suffering.

Conclusion: The management of patients with lipedema in France is far from optimal and make the journey of these women long, complex and expensive, contributing to their physical and psychological suffering.

Jungkwan KIM, Jaemoon YUN, Jiyoung KIM, Hajin KIM

Seoul National University Of Hospital, Seoul, Corée (République de)

Context: Combustible cigarette smoking is known to elevate hemoglobin (Hb) levels primarily through carbon monoxide mediated erythropoietic stimulation. In contrast, the hematologic effects of exclusive e-cigarette use remain poorly defined, especially in primary care settings where clinicians frequently counsel on tobacco and nicotine products.

Objectives: To compare Hb concentrations across four tobacco use patterns non-smoking, exclusive e-cigarette use, exclusive combustible cigarette smoking, and dual use and to determine whether exclusive e-cigarette use is associated with Hb elevation.

Methods: This observational analysis used nationally representative data from adult men aged ≥19 years with complete information on

smoking behavior and e-cigarette use. Participants were categorized into four mutually exclusive groups: non-smokers, exclusive e-cigarette users, exclusive combustible cigarette smokers, and dual users. Hemoglobin concentration was the primary outcome. Individuals without Hb data were excluded from regression analyses. Age-adjusted linear regression was used to evaluate Hb differences across groups, and predictive margins were estimated to obtain adjusted mean Hb levels.

Results: A total of 1,311 men met inclusion criteria, of whom 1,290 had available Hb measurements. Age-adjusted mean Hb levels were 15.31 g/dL in non-smokers, 15.19 g/dL in exclusive e-cigarette users, 15.54 g/dL in exclusive smokers, and 15.60 g/dL in dual users. Compared with non-smokers, exclusive combustible cigarette smokers ($\beta = 0.23$ g/dL, $p < 0.001$) and dual users ($\beta = 0.29$ g/dL, $p = 0.001$) showed significantly higher Hb levels. Exclusive e-cigarette use was not associated with Hb elevation ($\beta = -0.12$ g/dL, $p = 0.39$).

Discussion: These findings reinforce that Hb elevation reflects exposure to combustion-related toxicants rather than nicotine delivery. The absence of increased Hb among exclusive e-cigarette users suggests that non-combustible nicotine products do not trigger the compensatory erythropoietic response observed in combustible smoking.

Conclusion: Conventional cigarette smoking was associated with increased hemoglobin levels, whereas e-cigarette use showed no such association. The type of tobacco product should therefore be considered when evaluating hemoglobin elevation and its underlying mechanisms in primary care practice.

Context: Primary Health Care (PHC) plays a key role in health promotion and prevention of adverse events, especially in emergencies requiring immediate action. Choking and cardiopulmonary arrest (CPA) are notable causes of preventable deaths, often associated with insufficient basic emergency knowledge. In response to this need, a Primary Care Unit implemented a Basic Life Support (BLS) educational activity coordinated by the unit's physician, aiming to train professionals and community members to recognize critical signs and correctly perform choking relief and cardiopulmonary resuscitation (CPR).

Methods: The training was named "Reanimate Project: Anyone Can Be the First to Help", reflecting that, in XXX, "reanimate" is also used to mean "resuscitate". The first edition occurred in May 2025, in XXX, and initially involved the unit's staff—community health workers, dentists, nursing professionals, receptionists, and general services staff. Following positive results, the initiative expanded over five editions to include professionals from local health and education sectors. Each cohort had about 12 participants, ensuring close interaction and supervision. The activity consisted of two phases: a theoretical session using PowerPoint slides and instructional videos to address choking recognition, CPA signs, scene safety, activation of emergency services, and the BLS chain of survival; and a practical session using pediatric and adult manikins, bag-valve-mask devices, and peer simulations that enabled immediate technique correction. Strengths included small

groups, multiprofessional participation, and realistic training materials. Limitations involved limited time for more complex scenarios and the absence of formal quantitative assessment.

Originality: Providing recurring BLS courses within PHC, using active learning, multiprofessional engagement, and intersectoral participation, represents an innovative practice. Reports of continuous, structured BLS training with manikins directly in primary care settings are still uncommon.

Lessons learned and future implications: The experience highlighted the need for hands-on emergency training. Small groups and simulations improved learning and confidence. Future steps include expanding sessions, incorporating pre- and post-training evaluations, and promoting dissemination of BLS skills in schools and other community spaces.

Discussion: The continuity of the course demonstrates its educational relevance, strengthening autonomy, teamwork, and local emergency preparedness.

Conclusion: The initiative reinforced PHC's strategic role in BLS education and contributed to building a more prepared, resilient, and safer community.

ID 2205- The Anti-Inflammatory Roles of Vitamin D for Improving Human Health

Florian PEZON

None, Plerguer, France

Context: During Roman Antiquity, the entire Empire was a medical desert. The entire? No! Some doctors, trained in medical schools, practiced their art, especially in Rome and in large cities. But the competition with a less rational approach to medicine was fierce…

Objectives: We examined what factors may have influenced medical demographics at the time and what the consequences may have been for the population.

Methods: We used texts from ancient authors and epigraphic evidence.

Results: First, Roman prejudices about Greek rational medicine persisted long after its introduction to Rome and a more traditional, ancestral medicine, under the direction of the pater familias, remained the norm for a long time, at least among the upper classes. Even several centuries later, most practitioners were Greeks. The presence of doctors, sometimes highly specialized, was greater in cities, particularly in Rome, so much so that Cicero (1st century BC) lamented the fragmentation of the art of medicine into parts. On several occasions, some wealthy cities tried to attract doctors with advantageous policies: salary, various tax exemptions... But these advantages were strictly controlled with a veritable "numerus clausus" of public positions. Conversely, rural areas were less "well-equipped", although the itinerant doctor, traveling from town to town, was the norm in antiquity. Thus, Glaucon took care to ask his friend, the famous Galen (2nd AD), to write him a book about treatment of fevers and tumors when he had to leave Rome.

Discussion: So, despite Galen's virulent attacks against those whom we would call "charlatans" today, who used magical methods, it must be acknowledged that many patients probably did not have a wide choice among those considered capable of providing them with relief from their illness, and even less so among doctors trained in rational medicine. Moreover, even among the latter, some representatives of the Methodist school, the most important one at the beginning of the Empire, believed that medicine could not be provided individually due to a lack of doctors.

Conclusion: Medical demography, despite its current relevance, is a subject older than our contemporary era. Even in Roman antiquity, it forced both patients and doctors to change their practices.

Ho Cheol SHIN

Vhs Medical Center, Seoul, Corée (République de)

Context: Chronic fatigue commonly encountered in primary care have various aspects. As fatigue becomes more severe, cognitive dysfunction such as poor concentration and increased reaction time become more pronounced. However, there are few ways to objectively measure these symptoms. There are some reports that CFFT helps evaluate such symptoms, but the results are inconsistent.

Objectives: This study investigated the usefulness of CFFT as an objective tool for evaluating cognitive dysfunction of patients with fatigue symptom

Methods: Patients aged 20~65 who complained of chronic fatigue and visited family medicine clinic were studied. The severity of fatigue symptoms was assessed by a series of questionnaires such as VAS-F (Visual Analysis Scale for Fatigue), Chalder's Fatigue Scale, SDS, STAI, SRI and a CFFT equipment. A Case-control study was conducted comparing the results with control group not complaining of fatigue symptoms.

Results: This study included 509 patients with chronic fatigue and 194 healthy controls. The mean of CFFT was 36.9±3.2 Hz in the fatigue patient group and 38.7±4.5 in the control group ($p<0.01$). By age group, the CFFT mean of fatigue patients and control group was 36.9±2.6 and 38.9±4.9 ($p<0.05$) in those in 20s, 36.8±2.7 and 38.5±4.1 ($p<0.01$) in 30s, 36.7±3.7 and 38.8±4.6 ($p<0.01$) in 40s, and 37.0±3.4 and 38.8±3.6 ($p<0.05$) in their 50s, respectively. The correlation between CFFT and the fatigue scale was r=-0.165 ($p<0.01$) with VAS-F, and r=-0.228 ($p<0.01$) with mental fatigue of Chalder's Fatigue Scale. The correlation between CFFT and depression, stress scale was r=-0.193 ($p<0.01$), r=-0.213 ($p<0.01$), respectively.

Discussion: In this study CFFT was lower in the fatigue patient group and tended to decrease as the subjective fatigue symptom became more severe. However, due to various limitations such as measuring equipment, environmental conditions, the effects of psychopharmacological drug use, and the lack of information on the extent of minimal difference that have clinical significance, further detailed studies are needed.

Conclusion: Based on the results of this study, CFFT is considered to be a useful objective measurement tool that can be used in conjunction with existing tools to assess fatigue symptoms easily, and more comprehensively. Nonetheless, further studies are needed for definite clinical evidence.

ID 1154- The association between metabolic–body mass index phenotype and risk of gastric cancer: A retrospective cohort study

Victoria AZAROV

Semmelweis University, Budapest, Hongrie

Context: Women working across science, technology, engineering, mathematics and medicine (STEMM) continue to encounter structural barriers such as the glass ceiling, the motherhood penalty, gendered expectations and systemic bias. These barriers contribute to systemic patterns including the leaky pipeline, underrepresentation and visibility gaps. Although many institutions have implemented Gender Equality Plans (GEPs), Equality, Diversity and Inclusion (EDI) strategies and related frameworks, feedback raised during the discussion section of a recent international policy workshop highlighted that such measures are often implemented as symbolic “tick-box” obligations. This reflects a broader gap between structural policy and cultural reality, compounded in some contexts by internalized modesty norms that discourage women from seeking or accepting visibility and can limit how they express or pursue their ambitions and capabilities.

Methods: A grassroots English-language interview initiative (XXX) was launched within a student-run organizational context to highlight women's experiences across diverse STEMM fields and was made available as a video series. The initiative created a supportive space for guests to discuss professional journeys, gendered challenges, cultural expectations, emotional labor, underrepresentation, advice for future generations of women in STEMM, and the role of mentorship and support networks. Conversations also revealed the importance of relatable role-modelling, confidence and pride. The English-language format further expanded the reach of these narratives beyond local contexts.

Originality: To our knowledge, this is the first publicly accessible English-language narrative initiative of its kind in its regional context, offering a cultural complement to existing policy-based equality mechanisms.

Lessons learned and future implications: Interview narratives highlight that structural tools such as GEPs and EDI frameworks alone cannot address cultural expectations, visibility gaps or self-limiting norms. Visibility initiatives and relatable role models can strengthen self-belief and inspire younger women to see themselves in STEMM pathways, encouraging them to aim higher.

Discussion: Narrative storytelling adds a humanistic and culturally responsive dimension to gender-equity work. Presented in English, these stories reach wider audiences, building connection and solidarity. This visibility supports the cultural shifts needed alongside structural equality efforts.

Conclusion: Grassroots visibility initiatives such as XXX help bridge the gap between policy and lived experience, supporting broader efforts toward equitable, inclusive and humanistic healthcare and scientific environments.

(1) Institute Of Primary Care, University Of Zurich, Zürich, Suisse
(2) See-Spital Horgen, Horgen, Suisse

Context: Although periodic health examinations (PHEs) are among the most common reasons for encounter in developed countries, reflecting both patient demand and the role of prevention in general practice, the value of PHEs remains a matter of debate. Evidence indicates that many preventive interventions offer limited benefit and may even cause harm. On the other hand, patients frequently ask for extensive testing during PHEs. This mismatch between limited evidence and patient expectations is a challenge for the doctor-patient relationship and may contribute to overuse of low-value interventions and underuse of evidence-based interventions (evidence–performance gap) with clinical, public health and ethical implications.

Objectives: This workshop aims to (1) update participants on evidence-based recommendations of preventive interventions in a PHE setting; (2) share real-world experiences with PHEs in general practice; (3) identify barriers and enablers to closing the evidence–performance gap in preventive care using PHEs as low-threshold access for best clinical practice, and (4) discuss potential solutions and present a selection of fact sheets for patients, as an example of how to deal with patient expectations.

Teaching method and workshop: Teaching method: The session will combine brief evidence-based lectures using electronic voting for instant audience feedback, small-group discussions to explore practice variations, and a moderated plenary to synthesize strategies for aligning patient ex

Expected outcomes: Participants will be encouraged to reflect on their own consultation patterns and to co-create practical approaches to more effective, personalized,

and sustainable preventive care in the setting of PHEs and beyond.

Conclusion: The workshop provides evidence, experience sharing, debating and developing a best-practice approach for preventive interventions in the setting of PHEs in general practice.

ID 1737- The Authentic Physician – Personal Branding for Development & Wellness

Osman CAGLAR

Université De Liège, Liège, Belgique

Context: HbA1C is the mainly used biomarker in the glycemic monitoring in diabetic patients. The dosage may be altered in some clinical situations such as hemoglobinopathies, hemolysis, chronic renal failure (CRF), splenomegaly, hereditary spherocytosis or even pregnancy, leading clinicians to question its reliability. Glycated albumin (GA), Fructosamine (FA) and continuous glucose monitoring (CGM) devices are presented as alternatives by guidelines, but their clinical use remains unclear.

Objectives: To asses the usefulness of the alternatives in diagnosis and follow-up of diabetes

Methods: A narrative review with a methodology borrowed from a scoping review was carried out. A bibliographic research inspired by the PRISMA recommendations was conducted on the Pubmed and Cochrane databases to identify systematic reviews, narrative reviews and meta-analyses comparing these alternatives to HbA1C, published between 2015 and 2025. Results from selected studies have been compared to guidelines from 3 professional organizations : American Diabetes Association (ADA), National Institute for Health and Care Excellence (NICE) and European Association for the Study of Diabetes (EASD).

Results: Although GA has its own limitations, a better correlation with blood glucose variations in CRF than HbA1C has been shown in some studies. The diagnostic accuracy of FA seems to be lower than GA. CGM devices are more accurate at detecting blood glucose variations and help to reduce episodes of hypoglycemia.

Discussion: Low level of evidence and practical limitations currently prevent the use of these alternatives in clinical practice. GA seems most promising in hemodialysis patients and CGM devices in patients with significant glycemic variability. FA is the least studied marker.

Conclusion: When HbA1C lacks reliability, alternatives appear to show some usefulness. FA remains the least studied marker, AG and CGM devices appear to show stronger evidence. Although these alternatives have been integrated into recent guidelines, a lack of harmonization between the professional organizations is currently observed. Further studies are needed to validate their clinical utility.

Context: Secondary stroke prevention can reduce the risk of recurrent stroke by 90%. Special primary care units enhance the prospect of secondary prevention in diabetics.

Objectives: To assess the contribution of our diabetes- lipid unit to the secondary stroke prevention in diabetics with a first-ever ischemic stroke two years after the event.

Methods: All the patients included in the survey (N=65) were under medical supervision in our diabetes- lipid unit every three months

for at least two years. 35 diabetic men and 30 diabetic women who suffered a first-ever ischemic stroke were included in the survey. Patients with AF, CAD, HF(NYHA>2) and smokers were excluded. BMI, HBA1c, LDL and TG were always tested and interventions were made accordingly. Finally, we checked who of these patients had a second event in a two-year period after the first one.

Results: Among the diabetic men, 82.9% had high LDL, 51.4% had high TG and only 14.2% had a normal BMI. After two years of therapy 71.4% achieved the LDL goal, 94.2% the TG goal, 40% had desirable HBA1c, yet 22.9% increased their BMI. Among the diabetic women, 90% had high LDL, 30% had high TG and only 6.7% had a normal BMI. After two years of therapy 60% achieved the LDL goal, 100% the TG goal, 73.3% had desirable HBA1c, yet 16.7% increased their BMI.

Discussion: After two years of therapy at our Special diabetes-lipid primary care unit only 5/35 men and 4/30 women had had a second cerebral ischemic event.

Conclusion: Special diabetes-lipid primary care units contribute to the close monitoring of risk factors and therefore avoidance of recurrent stroke

ID 2034- The Boundaries Prescription: Treating Co-Dependency in General Practice

Giovanni COLUCCI [(1)], Maria ZAMPARELLA [(2)]

(1) Past General Practitioner Asl Ta Distretto 5, Martina Franca, Italie
(2) General Practitioner, Bari, Italie

Context: In the DIAMOND study (in Italy), the epidemiological data on AC derive from real-world studies conducted on large populations attending cardiology clinics. The red flags are very varied in the pathology and do not guide the diagnosis

Objectives: To evaluate naive subjects for cardiac amyloidosis through red flags and laboratory and instrumental investigations

Methods: 15 General Practitioners participated in the study (Statte-Martina Franca 22,000 users), from the management archives we enrolled through a quarry (age ≥65 years, Heart failure, CKD, AF, Arrhythmia, Diarrhea, CTS, Persistent low back pain, Hypotension, azotemia, creatinine) 6369 patients who had clinical symptoms or instrumental data suspicious for AC. M: 2845 (44.7%); F: 3524 (55.3%), Age (mean ± STD): 76.9 ± 7.9.

Results: Symptoms suggestive of AC: Lp (12.4%); STC (8.4%); D (6.3%); SC (4.9%); AF (4.2%); A (3.2%). On 3781 patients with Urea and Creatinine, we calculated UCR and GFR with EPI-CKD and related them to AF. In a logistic regression [OR: 1.49 (1.15-1.86); p: 0.015]; Age [OR: 1.03 (1.01-1.05); p: 0.01]; Sex [OR: 0.99 (0.75-1.32); p: 0.79].

Discussion: Having a UCR ≥ 30 - ≤ 100 the risk of having AF is high, associated with GFR. Monitoring the UCR is crucial for the management of critically ill patients, as it provides information not only on cardio-renal function but also on water balance and protein metabolism.

Conclusion: Having a UCR ≥ 30 - ≤ 100 the risk of having AF is high, associated with GFR. Monitoring the UCR is crucial for the management of critically ill patients, as it provides information not only on cardio-renal function but also on water balance and protein metabolism.

Context: Bullous pemphigoid (BP) is the most common autoimmune blistering disease in elderly patients. DPP-4 inhibitors (gliptins) have emerged as significant triggering factors, with a 2-3 fold increased risk. We present a case successfully managed with biological therapy after corticosteroid-related complications.

Methods: A 74-year-old male with type 2 diabetes (on linagliptin since October 2024), hypertension, and COPD presented in January 2025 with progressive pruritic lesions evolving over two months. Examination revealed generalized eczematous plaques with tense and flaccid blisters on trunk and extremities, plus oral hemorrhagic bullae. Skin biopsy with direct immunofluorescence demonstrated linear C3 (+++), IgG (++), and IgM (+) deposition at the basement membrane zone. Anti-BP180 antibodies confirmed the diagnosis. Initial treatment consisted of linagliptin withdrawal, prednisone 60mg/day (0.75mg/kg/day), and topical triamcinolone 0.1%. Despite appropriate dosing, the patient showed limited response with persistent new blister formation. Critically, he developed a D6 vertebral fracture in April 2025, a severe corticosteroid complication. Given disease refractoriness, diabetes comorbidity, and corticosteroid-related morbidity, dupilumab was initiated (600mg loading dose, then 300mg bi-weekly). This enabled rapid corticosteroid tapering to 5mg/day within four months, with complete clinical remission maintained at six-month follow-up.

Originality: While dupilumab is approved for atopic dermatitis, its use in BP remains off-label despite growing evidence. This case uniquely demonstrates dupilumab's dual benefit: achieving disease control while preventing further corticosteroid complications in a high-risk patient with multiple comorbidities.

Lessons learned and future implications: This case highlights three critical points: (1) maintaining high clinical suspicion for gliptin-induced BP in diabetic patients with new-onset bullous eruptions; (2) early consideration of steroid-sparing agents in elderly patients with significant comorbidities; (3) dupilumab's potential as first-line therapy in selected cases rather than salvage treatment

Discussion: Gliptin-induced BP requires prompt recognition and drug withdrawal. Traditional high-dose corticosteroids pose significant risks in elderly diabetic patients. Dupilumab emerges as an effective steroid-sparing alternative, achieving rapid disease control while minimizing complications. Further research should establish optimal timing for biological therapy initiation in high-risk populations.

Conclusion: Dupilumab offers a paradigm shift in BP management, particularly for patients with corticosteroid contraindications or complications. Prospective studies are needed to establish optimal timing and patient selection criteria for biological therapy in BP.

Aga Khan University Hospital, Karachi, Pakistan

Context: The evolution of Employee Health and Wellness Program launched in 2019 for early detection, prevention and management of physical and mental health concerns among full-time employees. Guided by emerging data and needs, program has expanded over successive screening cycles.To date, 3,674 employees have been screened.

Methods: First screening cycle in 2019 revealed two major findings. Hepatitis C–positive employees were identified predominantly from housekeeping department, received timely treatment. This led to creation of a policy requiring universal Hepatitis C screening at pre-employment—initially for housekeeping, later expanded to all employees.The same cycle also identified multiple employees at risk of diabetes and hypertension, who were treated. Mental health assessment was introduced which helped flag early signs of low mood and stress. In 2022, the second cycle included detailed psychological assessment. Physical health findings highlighted increased cardiometabolic risk with diabetes and hypertension. The mental health data reaffirmed significant stress. By 2025, the program expanded further by incorporating Coronary Calcium Scoring to detect subclinical coronary artery disease and prevent fatal cardiac events by timely intervention. Mental health screening was strengthened enabling identification of depression, anxiety, and

stress.Confidential referrals were made to a dedicated psychologist, ensuring anonymity and help-seeking. Strengths of the program include progressive refinement, evidence-based expansion and treatment. Limitations involved logistical constraints and ensuring consistent participation.

Originality: Wellness program combining infectious disease screening, chronic disease management, advanced cardiac risk assessment, and structured mental health evaluation reflects a commitment to inclusivity, equity and fraternity within the workplace. Promoting equitable health for all irrespective of job category or socioeconomic status to ensure employees feel valued and protected.

Lessons learned and future implications: Improving program regularly, continuous data monitoring, expanding services and policies as new needs arise. Future directions may include workplace resilience training, health promotion and regular digital health monitoring.

Discussion: Early identification enabled timely treatment and organizational policy reform. Identification of early cardiometabolic risks strengthened preventive cardiovascular care reducing fatal cardiac events. Combined with structured mental health assessments to support comprehensive physical and mental well-being among employees

Conclusion: This program demonstrates how comprehensive, tailored wellness programs strengthen preventive care, enable timely intervention and support sustained well-being, contributing to a healthier, resilient workforce

ID 453- The contribution of a special Diabetes and Lipids Primary Care Unit to the secondary prevention of ischemic stroke in diabetic patients

Margot DURAIN

Docteur, La Motte Servolex, France

Context: The dietary supplement (DS) market is booming, as is the world of sports, particularly running. These trends are intertwined, with athletes consuming more and more DS to enhance their performance. DS are not regulated products, and their composition remains unreliable, with a particular risk of contamination by doping substances. Furthermore, patients, who are the primary target of marketing and social media, sometimes abuse DS in order to quickly respond to some difficulties. This consumption may mask underlying problems such as poor lifestyle choices, a poor relationship with sport or food, or more serious medical conditions. It then becomes difficult for users to sort through the information and consume these products safely and knowledgeably.

Objectives: In this context, we sought to gather reliable information on DS to create a preventive intervention on the use of dietary supplements by runners, aimed at improving their use and introducing an educational framework on nutrition.

Methods: This work therefore consisted of a review of the literature on DS, whose information has been cross-checked with French and European recommendations as well as with various expert consensus opinions. A preventive intervention has been developed using educational research to maximize its educational impact. A digital flyer was also designed, allowing athletes to keep a copy of the recommendations and nutritional information relating to DS. The intervention was performed to a few volunteer athletes with the aim of gathering opinions on the relevance of both the presentation and its content and evaluating the initial areas for improvement.

Results: 15 DS have been selected and reviewed, and a presentation which took form of a slideshow has been created.

Discussion: This subject takes place in a world of overcomsuption were everything should be avaliable quikly and where patients seek for easy solutions to their problems, neglecting impact of nutrition on health and performance, bad nutrition being responsible of a lot of pathological issues.

Conclusion: This work makes it possible, through a subject that interests the targeted

population, to carry out more general nutritional prevention and to disseminate reliable, safe, and scientifically validated advice and recommendations on alimentary and DS consumption.

Context: Sleep duration is recognized as a modifiable factor influencing cardiometabolic health. However, its association with apolipoproteins—sensitive biomarkers of atherogenic dyslipidemia—remains inadequately examined in community and primary care populations.

Objectives: To investigate the relationship between habitual sleep duration and apolipoprotein profiles, focusing on ApoB, ApoA1, and the ApoB/A1 ratio, and to compare these associations with traditional lipid markers.

Methods: We analyzed 4,677 adults from the 2007 Taiwanese Survey on Hypertension, Hyperglycemia, and Hyperlipidemia. Sleep duration was categorized as short (<7 hours), normal (7–9 hours), or long (>9 hours). Linear and logistic regression models were applied with sequential adjustments for age, sex, smoking, alcohol use, and physical activity. Outcomes included ApoB, ApoA1, ApoB/A1 ratio, and conventional lipid parameters.

Results: Of all participants, 57.6% reported short sleep, 39.1% normal sleep, and 3.4% long sleep. After full adjustment, long sleep was associated with higher ApoB (β=+3.59 mg/dL; 95% CI: 0.07–7.11), lower ApoA1 (β=–4.71 mg/dL; 95% CI: –7.89 to –1.52), and an increased ApoB/A1 ratio (β=+0.056; 95% CI: 0.025–0.088). Long sleep also increased the odds of high ApoB (OR 2.00; 95% CI: 1.00–3.68) and high ApoB/A1 ratio (OR 1.93; 95% CI: 1.34–2.81). Short sleep showed no significant deviations from normal sleep. Traditional lipid measures demonstrated minimal variation across sleep categories.

Discussion: Findings suggest a U-shaped relationship between sleep duration and apolipoproteins, driven predominantly by adverse profiles in long sleepers rather than short sleepers. Apolipoproteins appeared more sensitive than conventional lipid markers in detecting sleep-related metabolic risk.

Conclusion: Long sleep duration (>9 hours) is independently associated with a more atherogenic apolipoprotein profile, while short sleep shows no meaningful differences. Incorporating sleep assessment and apolipoprotein testing may enhance cardiometabolic risk detection in primary care.

Context: Food insecurity (FI) is linked to adverse physical and psychological health outcomes, including increased risks of addictive behaviors and eating disorders. Emerging evidence indicates that FI may increase

vulnerability to muscle dysmorphia (MD), defined as obsessive preoccupation with muscularity and leanness. However, the mechanisms through which FI influences exercise and eating-related psychopathology remain insufficiently clarified.

Objectives: This study investigates whether MD mediates the relationships between FI and both exercise addiction (EA) and muscularity-oriented eating (MOE). Additionally, it examines whether resilience, the capacity to recover from adversity, moderates these mediating effects. Gender differences were further explored to inform tailored intervention strategies.

Methods: A total of 1,500 young Taiwanese adults (Mage = 22.2 years) completed an online survey. Structural equation modeling was used to examine the relationships among FI, MD, EA, and MOE. Mediation analysis tested whether MD explained the associations between FI and both EA and MOE. Moderated mediation was conducted to determine whether these effects differed by resilience levels. Gender differences were assessed via measurement invariance testing.

Results: FI showed indirect associations with increased risks of EA (β = 0.431, [0.312, 0.563]) and MOE (β = 2.3, [1.707, 2.887]) via MD. Gender differences emerged, with FI more strongly predicting MOE risk among males and EA risk among females. Resilience moderated the mediating paths between FI and EA (index = 0.066, [0.032, 0.105]) and between FI and MOE (index = 0.341, [0.163, 0.528]).

Discussion: FI may increase behavioral addiction and disordered eating through intensified body image concerns. Individuals with higher resilience appeared more attentive to their body image, with males emphasizing muscularity and females focusing on leanness. MD plays a central role in linking FI to maladaptive exercise–eating behaviors. Strengthening resilience may help attenuate the adverse effects of FI in young adults.

Conclusion: Food insecurity indirectly elevates risks of exercise addiction and muscularity-oriented eating through heightened muscle dysmorphia. While resilience partially buffers these adverse effects, the degree of body image awareness differs between males and females. Muscle dysmorphia emerges as a pivotal psychological mechanism, underscoring the importance of targeted resilience-building and gender-sensitive interventions to mitigate FI-related risks.

Context: Lipschütz genital ulcers are a rare condition affecting young women, usually caused by viral infections, most often Epstein-Barr virus (EBV). They pose a diagnostic challenge since they do not fall into the main causative categories such as sexually transmitted infections (STIs) or autoimmune processes.

Methods: A healthy 25-year-old woman presented to her Family Doctor after urgent evaluation by Gynecology due to isolated genital ulcers with well-defined edges and clean bases, with palpable bilateral inguinal lymphadenopathy as the only abnormal finding on physical exam. She reported no improvement despite completing antiviral treatment prescribed for suspected primary herpes simplex virus infection. Her doctor requested cultures of ulcer exudate, endocervical, and urine samples. A few days later, she returned with asthenia, sore throat, fever, and right hypochondrium pain without palpable organomegaly. Additional screening was performed including serologies for hepatotropic viruses, EBV, and cytomegalovirus (CMV), as well as blood tests including complete blood count, biochemistry with liver profile, and autoimmunity. The review showed lymphocytosis with elevated transaminases and positive serologies (IgM and IgG) for EBV

and CMV. Given these results and persistent ulcers, she was referred to Gynecology via teleconsultation, which concluded the diagnosis of Lipschütz ulcers in the context of infectious Mononucleosis. She evolved favorably with symptomatic management.

Originality: In this clinical case, Lipschütz ulcers were the only initial manifestation, unlike most cases reported in scientific literature where they are associated with infectious symptoms from the onset.

Lessons learned and future implications: To avoid unnecessary treatments, it would be advisable to disseminate differential diagnostic algorithms in which, especially in young women regardless of sexual activity, non-sexually transmitted infectious causes are considered.

Discussion: Gynecology interconsultation can be a key tool for early diagnosis, considering that genital ulcers may be the only presenting sign in some cases.

Conclusion: It is important to emphasize the need to consider infectious mononucleosis as a differential diagnosis of genital ulcers by exclusion. Gynecology interconsultation is proposed as a good resource for early identification of an uncommon condition such as Lipschütz ulcers.

ID 2178- The Effect of the COVID-19 Pandemic on Smoking and Nicotine Dependence Levels in Family Medicine Residency Students

Hannah KIELTY, Finola MINIHAN

Yew Medical Centre, Balbriggan, Dublin, Irlande

Context: Sick day rules are critical guidelines that help patients manage their prescribed medications safely during periods of acute illness, such as vomiting, or dehydration. These

rules are especially important for individuals with chronic conditions. Failure to adjust or withhold certain medications during illnesses can lead to serious complications, including hypoglycaemia, or hypotension. Despite their importance, awareness of sick day rules remains low among patients and healthcare providers.

Objectives: The aim of this audit is to identify patients taking SGLT2 inhibitors, increase awareness for patients by using patient information leaflets, and for healthcare providers by using pop up alerts on charts. We hoped that with this audit and the implementation of changes we would hit a target of 90% of our patients on SGLT2 inhibitors having sick day rules discussed and information provided. Although this target was not achieved, we did achieve a significant improvement.

Methods: We used SOCRATES software system to identify patients on SGLT2 inhibitors. Notes, and medication review entries were reviewed and an audit spreadsheet was completed. We designed a template information sheet to be accessed through their patient file and provided to them on the day of review. We also introduce a pop-up alert on the patient's chart to remind healthcare staff to discuss Sick Day Rules.

Results: In August 2024, 76 patients were included in our audit. On reaudit in March 2025, we had 74 patients included. We increasesd our Sick Day rule discussions from 21% to 53% during this audit time period. Written information provided increased from 19% to 87%

Discussion: This highlights the lack of appropriate advice provided to patients re Sick Day rules, focusing on SGLT2 inhibitors. Once particular measures were introduced to support healthcare professionals in providing this advice with memory aids, and take home leaflets, this led to an increase in discussions.

Conclusion: We continue to offer patient leaflets re Sick Day Rules. We will continue to use alerts to remind staff to provide advice. We will incorporate SGLT2 inhibitor sick day advice into structured medication review templates and also recommend that a pop- up alert be introduced at time of first prescribing of SGLT2 inhibitors.

ID 2243- The effects of adapted physical activity among people with disabilities (PSH) aged 18 to 59: a scoping review

Johnathan SUN, Jibran KHAN, Oisin BRANNICK

King's College London, London, Royaume-Uni

Context: Chronic kidney disease (CKD) substantially increases cardiovascular morbidity, risk of renal failure, and premature mortality. UK guidelines NICE TA775 (2022) recommends dapagliflozin for patients with CKD (eGFR 25-75 mL/min/1.73m²) on optimised ACEi/ARB therapy who also have type 2 diabetes or significant albuminuria (ACR ≥22.6 mg/mmol). Large clinical trials have demonstrated the reno- and cardioprotective benefits of SGLT2-inhibitors, yet real-world uptake in CKD patients remains suboptimal, particularly in primary care where most CKD is managed.

Objectives: To evaluate SGLT2-inhibitor implementation in primary care by identifying CKD patients eligible for dapagliflozin and examining renal monitoring patterns.

Methods: A retrospective cross-sectional analysis was conducted in a UK general practice setting using electronic health records (April 2025). Adults (≥18 years) previously recorded as CKD G3a-G5 were included. Exclusion criteria were type 1 diabetes and current SGLT2-inhibitor use.

Results: Of 158 patients with CKD 3a-5, 38 (24.1%) met general TA775 criteria. After exclusions (n=25), 13 patients (8.2%) remained eligible for dapagliflozin. Additionally, 32 patients (20.3%) were overdue for renal testing, including 15 patients (9.5%) with no ACR result on record. These findings indicate gaps in essential testing and prescribing processes needed to identify and treat eligible patients.

Discussion: Suboptimal ACR testing, incomplete ACEi/ARB optimisation and variability in clinician familiarity with updated CKD guidance likely contributed to low eligibility recognition. These results reflect national data: the 2017 National CKD Audit (NCKDA) reported proteinuria measurement in <15% of non diabetic and 54% of diabetic patients. Global KDIGO guidelines align closely with UK guidelines on dapagliflozin prescription, demonstrating the growing importance of addressing this implementation gap.

Conclusion: This study identifies a substantial mismatch between NICE TA775 guidance and real-world CKD management. System-level interventions such as electronic alerts, strengthened eGFR/ACR recall systems, and structured medication reviews may improve uptake of dapagliflozin and overall CKD care quality. Given the international approval of SGLT2-inhibitors for CKD, implementation gaps identified here may highlight opportunities for stronger CKD management globally.

Context: Anticoagulation therapy is essential for patients with mechanical heart valve prostheses to prevent thromboembolic events. Warfarin and acenocoumarol are the most commonly used vitamin K antagonists (VKAs). This report presents the case of a 70-year-old woman with a mechanical mitral valve who had persistent difficulty maintaining an adequate International Normalized Ratio (INR) while on acenocoumarol.

Methods: The patient, who underwent mechanical mitral valve replacement seven years earlier, was managed with acenocoumarol and attended regular follow-ups with consistent INR monitoring. Despite this, her INR remained outside the therapeutic range (2.5–3.5) for almost one year, with fluctuations both above and below the target. This unstable control increased the risk of thromboembolic and bleeding complications. Given the repeated difficulties in achieving stable anticoagulation, clinicians decided to switch her to warfarin, a VKA with a longer half-life and more predictable pharmacokinetics. Transition to warfarin was performed with careful dose titration and bridging with low-molecular-weight heparin until reaching INR > 2. Subsequent monitoring aimed to stabilize anticoagulation. After two months on warfarin, the patient's INR consistently remained within the therapeutic range, reflecting markedly improved control compared with her previous treatment with acenocoumarol.

Originality: This case illustrates the challenges of anticoagulation management in patients with mechanical valves and highlights the need to individualize therapy based on clinical response.

Lessons learned and future implications: Although both VKAs are effective, elderly patients often exhibit greater INR variability with acenocoumarol. The patient's improvement after transitioning to warfarin supports its potential advantage in achieving more stable anticoagulation.

Discussion: Current evidence, including the PLECTRUM study, shows that time in therapeutic range is significantly higher with warfarin than with acenocoumarol in patients with mechanical prostheses, regardless of comorbidities or clinical characteristics. These findings suggest superior INR stability with warfarin. Earlier studies, such as Barcellona et al., reported no major differences in INR control but noted fewer overdosing episodes with warfarin. Overall, accumulated data favor warfarin due to its longer half-life and more consistent anticoagulant effect.

Conclusion: In conclusion, warfarin is generally preferred over acenocoumarol in patients with mechanical prostheses owing to its superior

INR stability, although acenocoumarol may remain an option in selected circumstances.

Dharani YERRAKALVA

University Of Cambridge, Cambridge, Royaume-Uni

Context: Mobile health (mHealth) apps are emerging as an intervention adjunct to support healthcare professionals (HCPs) in tackling high levels of obesity and physical inactivity seen in community settings. However, it is unclear to what extent their use is being integrated into routine primary care practice.

Objectives: To quantify how often primary care healthcare professionals (HCPs) are recommending physical activity (PA) and weight loss apps, and to identify barriers and facilitators influencing these recommendations.

Methods: We systematically searched four electronic databases for studies reporting recommendation rates of PA and weight loss apps by primary care HCPs, and barriers and facilitators to their recommendation. Study quality was assessed using the JBI Critical Appraisal Checklist for Studies Reporting Prevalence Data and the CASP Qualitative Studies Checklist. We then undertook a meta-aggregation synthesis.

Results: Four studies were included, all reporting recommendation rates and three exploring barriers and facilitators. Recommendation rates varied widely (13–65%), with lower rates for diet-specific (14%) and exercise-specific apps (13%). Common barriers included limited knowledge of apps, uncertainty about effectiveness, and time constraints related to both recommending apps and managing follow-up. Facilitators included access to trusted app lists, targeted app education, and integration of apps into clinical systems.

Discussion: Primary care HCPs' recommendation of PA and weight loss apps is highly variable. Evidence is limited by the small number and size of studies.

Conclusion: . Enhancing HCP knowledge through training and integrating apps into routine practice may increase recommendation rates.

ID 677- The experience of touch among general practitioners who practice dance. A qualitative study.

Amanda HOWE [(1)] , Sankha RANDENIKUMARA [(2)], Mariano GRANERO [(3)]

(1) University Of East Anglia, Norwich, Royaume-Uni
(2) Wonca South Asia, Colombo, Sri lanka
(3) Wonca Iberoamericana, Buenos Aires, Argentine

Context: All family doctors sooner or later have to make a policy – a "statement of principles designed to guide decisions, and lead to actions to achieve relevant outcomes". We rely on WONCA and Member Organisation leaders to do this at a national and international level, and have some excellent examples. But it is only recently that WONCA has begun to bring these together, to share them across our community, and help us all learn how to adapt these for our own needs and use

Objectives: At this workshop we shall share the latest findings from a global WONCA survey of what we already have: why these documents were created; who they are aimed at; what we know about their impact; and how we can use them more effectively and widely. We shall also do a presentation on what we know about writing and using policies effectively to advocate within our own contexts and settings. Attendees will be able to experiment with examples to share best practice, and ask questions / give feedback.

Teaching method and workshop: 5 minutes welcome and introductions 5 minutes; presentation of project findings and documents 10 minutes; presentation of workshop activities - with slides sharing exemplar documents and

key questions about value and use 15 minutes - small group exercises

Expected outcomes: Attendees will leave with both more awareness of what WONCA already can provide (policy access, policy and advocacy skill toolkit) and how they can use it for their own needs. We shall also feed any queries arising into our future briefings for members.

Conclusion: . This is part of the ongoing and widely supported work of the SIGPA, and uses the findings of our recent project as the evidence for the work shared. The workshop will also allow people to join the SIG, participate in a future analysis of policy needs and production, and findings will be fed into WONCA's ongoing priorities to assist members.

Context: Adapted Physical Activity (APA) improves quality of life (QoL) and functional capacities (FC) in patients with chronic conditions. Few data exist on the continuation of the effect in the medium term after the end of an APA program. Does the improvement in QoL and FC continue after the program has ended?

Objectives: The aim of this study was to measure the impact of an APA program on the QoL and FC of patients before, at the end, and at a distance after the end of the program.

Methods: Quasi-experimental single-center before/after study. Adult patients included by their general practitioner had: obesity and/or cancer and/or sarcopenia. The intervention consisted of an APA program of 3 supervised sessions per week for 4 months led by an APA teacher within a primary care health center (MSP). Assessments of QoL using the WHOQOL-BREF and FC using specific tests were conducted at T0, T1 (4 months), T2 (8 months), T3 (12 months), and analysis was performed with the Friedman test. The study received CPP approval.

Results: The sample included 122 patients. The main result is the significant improvement in overall QoL and its sub-dimensions, as well as FC, maintained up to 8 months after the program (p=0.002). Specific benefits were observed according to the subgroups analyzed. An increase in QoL and its relational component was observed in the first 4 months following the program. Age > 65 years seemed to lead to a faster decrease in benefits on QoL from the APA program.

Discussion: The study is ongoing to improve its power, particularly for subgroup analysis, which is a limitation of the current work. The strength was the absence of out-of-pocket expenses for patients and the proximity of the site, which allowed the inclusion of individuals with socioeconomic and/or mobility difficulties. Supporting patients in continuing physical activity in daily life after the program should be improved to maintain the positive impact on their QoL.

Conclusion: APA has a lasting positive effect on QoL and functional capacities. These benefits continue after the end of the program, highlighting the need to encourage ongoing physical activity after the intervention.

ID 106- The Future of Family Medicine from Family Physicians' Perspective

Suneet SANDHU BHARJ [(1)] , Thomas HALLETT [(2)]

(1) Reckitt Benckiser Group, Plc, London, Royaume-Uni
(2) Reckitt Benckiser Group, Plc, Hull, Royaume-Uni

Context: Air pollution is a growing global concern with well-documented effects on respiratory health. While much attention has been given to lower respiratory conditions whereas upper airway symptoms—particularly sore throat—has received comparatively less focus. This is especially relevant considering the

ever-rising pollution levels globally in recent years.

Objectives: This narrative review explores the relationship between exposure to environmental pollutants, and the incidence and mechanisms of sore throat. It identifies key pollutants involved, affected populations, and potential mechanisms.

Methods: Website searches (WHO, State of Global Air). Embase search 1: - Search string: 'pollution'/exp AND 'air pollution'/exp AND ('sore throat'/exp OR 'pharyngitis'/exp). - Date limit: 2010-2025. - Population: Newborn – 80+. - English language only. - In humans only. - Peer- reviewed. - 155 hits, 20 were deemed as relevant. Embase search 2: - Search string: 'pollution' AND ('sore throat':ti OR 'pharyngitis':ti). - Date limit: None. - Population: Newborn – 80+. - English language only. - In humans only. - Peer reviewed. - 11 hits, 7 were deemed as relevant. Studies that focused on infectious causes of sore throat, and on respiratory disorders that do not include sore throat were excluded.

Results: Pollution is increasing in recent years, with highest levels of the population being exposed above recommended limits of PM2.5 in Asia and Africa. Pollutants such as PM2.5, NO_2, SO_2, and O3 contribute to throat irritation through inflammatory and neurogenic mechanisms. Vulnerable populations including children, the elderly, and those with pre-existing conditions experience heightened symptoms.

Discussion: As pollution levels continue to rise globally, the incidence of sore throat is becoming an increasing health concern. Providing effective symptomatic relief can play a pivotal role in reducing the burden on overstretched healthcare systems by empowering individuals to manage mild symptoms through self-care. This is particularly critical in developing markets, where access to timely medical advice may be limited.

Conclusion: Air pollution often contributes to sore throat. This is of particular concern considering exceeding levels of pollution in various regions globally. Future research should aim to build a clearer picture and inform clinical practice.

(1) Ntu Lee Kong Chian School Of Medicine, Singapore, Singapour
(2) NUS Yong Loo Lin School of Medicine, Singapore, Singapour

Context: Osteoporosis is a growing concern in ageing Asian populations and can lead to preventable fractures and reduced quality of life. Early identification plays an important role in primary care, particularly in low-income settings with limited access to health resources. In Singapore, little is known about whether osteoporosis risk varies across ethnic groups within low-income communities; identifying such patterns may support more targeted screening.

Objectives: This study examined whether ethnicity is associated with Osteoporosis Self-Assessment Tool (OST) scores in a low-income population of community-dwelling adults in Singapore.

Methods: A cross-sectional community screening was conducted in Toa Payoh under the Neighbourhood Health Service. OST scores were calculated, and sex-stratified linear regression examined associations between ethnicity, chronic illness, and OST scores. Statistical significance was set at $p < 0.05$.

Results: Of 116 participants screened, 106 with complete data were included: 51 females (mean age 64.0 ± 10.3 years) and 55 males. (mean age 63.7 ± 11.0 years) In females, Chinese had the lowest mean OST score (−2.12 ± 3.24) vs Malay (0.60 ± 3.67), Indian (2.38 ± 3.31), and Others (2.87 ± 4.11). Adjusted for chronic illness, ethnicity strongly predicted OST score ($F(4,46)=4.38$, $p=0.004$, $R^2=0.28$); Malay ($\beta=2.98$, $p=0.008$), Indian ($\beta=4.75$, $p=0.002$), and Other females ($\beta=5.72$, $p=0.010$) had

significantly higher scores (lower risk) than Chinese females. Chronic illness was non-significant (β=−1.69, p=0.110). In males, OST scores were similar across ethnicities (range 0.49–4.30); neither ethnicity nor chronic illness was significant (F(4,50)=1.51, p=0.215)

Discussion: Even in a socioeconomically homogeneous population, ethnic differences in osteoporosis risk persist, particularly in females. Given the higher observed risk in Chinese females, community-based initiatives could prioritize screening and early intervention for this subgroup, using OST to efficiently identify those at greatest risk. Limitations include small sample size, with some ethnic subgroups having fewer than 5 participants, cross-sectional design, self-reported chronic illness, and recruitment from rental housing blocks with typical monthly incomes below SGD 1500 may limit generalizability.

Conclusion: Chinese females in low-income settings showed highest osteoporosis risk by OST screening. Targeted screening strategies for this subgroup may improve early detection in primary care.

ID 399- The GWAS (genome-wide association study) for hypertension based on the METS-VF score: using a KoGES analysis

Joana VELOSO GOMES, Filipa HENRIQUES DA SILVA, Jessica NUNES, Gracinda SILVA

Usf Estrela-Do-Mar / Uls Algarve, Faro, Portugal

Context: Municipalities are increasingly recognised as key players in promoting public health and wellbeing. However, integrated approaches that bridge primary care and local governance remain limited. Family doctors, with their comprehensive clinical expertise and deep community ties, are uniquely positioned to lead transformative health strategies at the municipal level.

Objectives: We propose the creation of dedicated Municipal Health Departments in every local council, led by a family doctor. These departments would coordinate health promotion, disease prevention, and community engagement initiatives, working in collaboration with primary care teams, local authorities, and community organisations. The family doctor leader would ensure that health policies are truly patient-centred, evidence-based, and adapted to local needs.

Methods: Expected Outcomes: This model aims to improve population health indicators, increase health equity, and foster more resilient communities. By placing family doctors at the helm, municipalities can better address local health challenges, respond rapidly to emerging issues, and strengthen the link between healthcare and other social determinants.

Results: Melhoria dos indicadores de saúde pública ao nível local, com redução da incidência de doenças evitáveis e promoção de estilos de vida saudáveis. Maior equidade no acesso aos cuidados de saúde, especialmente em populações vulneráveis ou desfavorecidas. Fortalecimento da resposta a emergências de saúde pública, como surtos, através de uma coordenação mais ágil e próxima da comunidade. Aumento da literacia em saúde e do envolvimento dos cidadãos em decisões relacionadas com o bem-estar do município. Criação de sinergias entre os serviços de saúde, autarquias e organizações comunitárias, potenciando intervenções mais eficazes e sustentáveis.

Discussion: The active involvement of family doctors in leading these structures may promote policies that are better tailored to the real needs of the population and strengthen the integration of primary care with municipal health strategies. This model may also help to enhance the role of the family doctor, increasing their participation in strategic decision-making and raising their visibility within the community and among policymakers.

Conclusion: Implementing Municipal Health Departments led by family doctors represents a bold step towards integrated, community-driven healthcare. This project offers a scalable blueprint for municipalities across Europe to

enhance health governance and empower family doctors as agents of change.

Joana VELOSO GOMES, Filipa HENRIQUES DA SILVA, Jessica NUNES, Gracinda SILVA

Usf Estrela-Do-Mar / Uls Algarve, Faro, Portugal

Context: Intimate partner violence (IPV) remains a persistent challenge with profound physical, mental, and social consequences. Effective intervention requires coordination between multiple sectors, including local authorities, police forces, Family Health Units from Primary Care, schools, and the portuguese Commission for Citizenship and Gender Equality (CIG).

Objectives: To develop, implement, and evaluate an integrated model for the prevention, early detection, and intervention in IPV, fostering synergies.

Methods: The project is structured around five key pillars: Awareness and Education - Regular sessions in schools, by focusing on gender equality, emotional literacy, and violence prevention, involving students, teachers, and parents. Early Detection and Referral - training for Family Health Units professionals, police, and local authority staff, in collaboration with CIG, to identify signs of IPV and activate integrated referral protocols. Community Response - Establishment of multidisciplinary support offices within the local authority, a local helpline, and direct involvement of CIG in defining intervention strategies. Monitoring and Evaluation: Joint definition of process and outcome indicators with CIG, and regular intersectoral meetings for assessment and adjustment of actions. Promotion of Local Policies: Development of recommendations and public policies, with CIG's input, to reinforce prevention and protection of victims.

Results: Expected Results: - Increased literacy on IPV and gender equality - Improved early detection and referral capacity - Reduction in unreported and recurrent cases - Strengthened local support network and positive impact on public policies

Discussion: Discussion: The project leverages the central position of family doctors by providing targeted training and integrated referral protocols, enabling them to work closely with local authorities, police, schools, and the Commission for Citizenship and Gender Equality (CIG). Multisectoral collaboration, supported by regular intersectoral meetings and shared resources, enhances the capacity of family doctors to address IPV holistically. Despite ongoing challenges—such as time constraints and the need for sustained inter-agency communication—empowering Family Health Units as frontline actors is key to the project's success and scalability.

Conclusion: Family doctors are key to tackling domestic violence — they know their patients, build trust, and act early. Investing in them is investing in safer, stronger communities.

ID 1288- The Hidden Danger of Toluene Solvent inhalation : A Case of Acute Neurological and Metabolic Disturbance

Florian STIGLER

Golden Nuggets, Stockerau, Autriche

Context: Family doctors often feel overwhelmed by guidelines and new studies, yet under-supported in translating evidence into everyday decisions. To address this, the "Golden Nuggets of Family Medicine", a micro-learning newsletter was created that offers 2-minute, evidence-based updates for GPs (on family-medicine.org).

Methods: This practice-based reflection draws on the first two years of the initiative. Each Nugget starts from a concrete clinical question raised in practice or by colleagues. We conduct a focused search of major journals and guidelines, appraise research studies, and present absolute effects and uncertainties in plain language. Drafts are shortened, structured into key messages, and checked by at least one GP colleague for realism and

readability before distributed as an open-access emails and PDFs.

Originality: Golden Nuggets combine rigorous evidence curation with focused brevity, understandable numbers and independence from industry funding. The format is "by GPs, for GPs", with readers' questions, critiques and topic suggestions shaping future issues and skills-focused Nuggets.

Lessons learned and future implications: By end-2025, after 1.5 years, the newsletter had attracted over 5,000 subscribers in more than 80 countries, largely through word of mouth. Readers report using Nuggets to prepare teaching, question guideline recommendations and discuss options with patients. The project also enabled a global survey of 468 GPs, showing how a simple newsletter can seed wider professional development and global collaborations.

Discussion: The initiative exposes tensions between trial evidence and overtreatment, between guideline enthusiasm and modest effect sizes, and between being understandable and oversimplification. Naming these tensions appears to validate the uncertainty inherent to family medicine and supports more reflective shared decision-making.

Conclusion: A curated, GP-led micro-learning newsletter can make evidence feel more accessible, trustworthy and clinically useful. The Golden Nuggets model is transferable and could be adapted by other primary care networks to support continuing education and practice-relevant research.

ID 1830- The impact of attention deficit disorder (ADHD) on the healthcare costs

Hye Rang BAK

Samsung Changwon Hospital, Changwon, Corée (République de)

Context: Hypertension is a leading global health burden, influenced by both metabolic dysfunction and genetic predisposition. While insulin resistance and visceral adiposity are established contributors, their interplay with genetic factors in hypertension remains incompletely understood. The Metabolic Score for Visceral Fat (METS-VF) provides a validated surrogate for visceral adiposity, yet the genetic architecture of hypertension stratified by METS-VF has not been fully explored.

Objectives: The study aims to investigate the contribution of genetic factors by evaluating the association between single nucleotide polymorphisms (SNPs) and hypertension in populations stratified by METS-VF levels.

Methods: We analyzed 70,513 participants from the Korean Genome and Epidemiology Study (KoGES). Participants were stratified into tertiles according to METS-VF values, and hypertension prevalence was compared across groups. Genome-wide association studies (GWAS) were performed separately for the lowest (T1) and highest (T3) tertiles, adjusting for age, sex, lifestyle factors. Genome-wide significance was defined as $p < 5 \times 10^{-8}$. Expression Quantitative Trait Loci (eQTL) analyses were conducted and presented in Supplementary Tables.

Results: Hypertension prevalence was substantially higher in the high-risk T3 group (47.3%) compared with the T1 group (14.6%, $p < 0.001$). GWAS revealed distinct genetic architectures between groups. In T3, 11 loci achieved genome-wide significance, compared with 6 loci in T1. The strongest signals were observed at rs16998073 in FGF5 and rs112735431 in RNF213, both associated with increased hypertension risk across tertiles. Conversely, variants near PRDM8 (rs17004846) and ATP2B1 (rs11105365) demonstrated protective effects. Notably, NT5C2 (rs12416331) was significant only in T1 and has been linked to hyperuricemia, suggesting a uric acid–mediated mechanism. Additional loci included ENPEP, SPTBN1, KCNK3, MYL2, CUX2, and ALDH2.

Discussion: To our knowledge, this is the first study to apply METS-VF to GWAS of hypertension. But, the observational design limits causal inference, and the absence of longitudinal data precludes assessment of temporal relationships.

Conclusion: This large-scale GWAS stratified by visceral adiposity identified both shared and unique genetic determinants of hypertension. The findings underscore the modifying effect of visceral fat on genetic associations. Compared with prior METS-IR based analyses, METS-VF may provide a more comprehensive index for integrating metabolic and genetic risk in hypertension.

ID 2114- The Impact of Climate Change on Family Medicine Practices: A Systematic Review

Gertruda STRIMAITE, Rima PILICIAUSKIENE

Vilnius University Faculty Of Medicine, Public Institution Karoliniškės Outpatient Clinic In Vilnius, Vilnius, Lituanie

Context: Insomnia is among the most prevalent sleep disorders worldwide, and in Europe, prolonged-release melatonin is approved as a safe, effective, and non-addictive treatment for patients over 55 years of age.

Objectives: To review the existing literature on the use of prolonged-release melatonin for the treatment of insomnia and to assess family physicians' prescribing practices and attitudes toward its use based on the conducted survey.

Methods: A literature review of the evidence published 2021-2025 on Pubmed. Search strings were formulated from the following term sets: 1) sleep, insomnia 2) melatonin and 3) study type. The search included free full-text articles in English and was limited to review articles and systematic reviews involving only human studies. And a survey of 22 family physicians from XXX Outpatient Clinic in XXX regarding the prescription of melatonin for the treatment of insomnia was carried out.

Results: Based on the literature review, prolonged-release melatonin (PRM) reduced sleep onset latency (SOL), especially in adults ≥65 years, and total sleep time (TST) as well as subjective sleep quality improved mainly in older adults. Among the surveyed physicians, 11 of 22 prescribed melatonin for insomnia, reporting moderate effectiveness in improving sleep onset, quality, and reducing nighttime awakenings, while noting unclear efficacy and limited scientific evidence as the main barriers.

Discussion: Data on long-term melatonin use remain limited, and the quality of available preparations is variable due to less stringent regulation compared with prescription medications.

Conclusion: Prolonged-release melatonin is a safe and moderately effective option for adults ≥55 years, and further research is needed to provide robust evidence on optimal dosing, duration, and long-term outcomes in primary care.

ID 1437- The Impact of Coordinated Care on the Rapid Diagnostic Pathway for Symptomatic Arrhythmia in an Older Adult: Case Report

Stefan BÖSNER [(1)] , Anna Christine STEINACKER [(2)]

(1) Department Of General Practice, Univerity Of Marburg, Marburg, Allemagne
(2) University Of Applied Sciences, Fulda, Allemagne

Context: Embodied patient-perspective simulations, which are also known as point-of-view simulations, are widely used in healthcare education to enable students to experience aspects of disability, care, and dependency from a patient's point of view. Common examples include navigating a wheelchair through a course, wearing an age-simulation suit, or completing tasks while blindfolded. These exercises are intended to foster empathy and stimulate reflection on patients' lived experiences. At the same time, the literature remains divided regarding their pedagogical value and the extent to which short-term simulations can create meaningful insights without reinforcing stereotypes.

Objectives: This exploratory study investigates both how patient-perspective simulations are implemented in nursing education and how they influence learning processes. It examines educators' pedagogical intentions, design choices, and debriefing strategies, as well as students' experiences of engagement,

reflection, and professional attitude development.

Methods: A qualitative research design was employed. Data were collected through focused interviews with nursing educators and nursing students and through participant observation based on focused ethnography. This allowed examination of the situated experience of the simulations and the pedagogical reasoning behind their implementation. Ethical approval was granted by a university ethics committee, and all procedures followed the principles of informed consent, non-maleficence, and the General Data Protection Regulation (GDPR).

Results: Preliminary findings indicate that students engage more deeply with learning materials and demonstrate enhanced reflective activity following the simulations. Educators emphasize that the value of these exercises lies less in producing an authentic adoption of the patient's perspective—which they largely consider unattainable—and more in creating structured opportunities for embodied experience, emotional involvement, and guided reflection.

Discussion: The pedagogical potential of patient-perspective simulations appears closely tied to educators' intentional design and reflective framing of the exercises. Influential factors include facilitators' preparation and debriefing practices, group dynamics, and the integration of real narratives from individuals with relevant lived experiences.

Conclusion: Initial findings suggest that patient-perspective simulations may support deeper learning involvement and contribute to developing reflective professional attitudes when thoughtfully implemented within an educational framework.

ID 1508- The Impact of Eating Behaviors on Type 2 Diabetes Mellitus Risk Assessment

Jack Min NG, Ching-Ping HSU, Hsin-Yin HSU

Department Of Family Medicine, Taipei Mackay Memorial Hospital, Taipei, Taiwan., Taipei City, Taïwan

Context: Progressive Resistance Training (PRT) is an effective intervention against osteoporosis and sarcopenia in aging populations, however, long-term adherence is poor. A recent feasibility study by Lin et al. (2025) addressed this by implementing a physician-guided educational model, achieving a 54.5% success rate in referring participants to community-based training.

Objectives: This secondary analysis aimed to identify baseline physiological characteristics that might predict successful referral to long-term training and to quantify the physiological adaptations resulting from the short-term intervention.

Methods: This is a secondary analysis of data from 11 subjects from the original trial. Non-parametric Mann-Whitney U tests were used for baseline comparisons, and the Wilcoxon signed-rank test for pre-post analysis. Key variables included bone mineral density (BMD) and Appendicular Lean Mass Index (ALMI) measured using whole-body dual-energy X-ray absorptiometry (DXA) scans, and fitness metrics including peak oxygen uptake (VO2), peak workload (W), and peak metabolic equivalents (METs) measured using cardiopulmonary exercise testing (CPET).

Results: Data from 11 female participants (median age 68) with diagnosed osteoporosis were analyzed; two also met criteria for sarcopenia. Participants were categorized as Successfully Referred (SR, n=6) or Unsuccessfully Referred (UR, n=5), however, only nine participants successfully completed the program. Baseline comparisons revealed no significant differences between SR and UR groups in osteoporosis severity (lumbar T-score, $p = 0.647$) and muscle mass (ALMI, $p = 0.201$). As expected for the brief program, no statistically significant post-intervention changes were observed in bone mineral density (lumbar T-score, $p = 0.859$) or muscle mass (ALMI, $p = 0.575$). Among the nine completers, the intervention elicited statistically significant increases in peak workload (27 W, $p = 0.011$) and peak oxygen uptake (VO2) (3.44 mL/kg/min, $p = 0.027$), irrespective of SR or UR groups.

Discussion: The lack of baseline physiological predictors suggests that adherence may be influenced more by psychosocial factors, such as a lower "perceived need" in fitter individuals, rather than physical capacity. Despite the short duration, the intervention successfully initiated meaningful cardiopulmonary improvements.

Conclusion: A brief, physician-guided PRT program can substantially improve fitness in older women with osteoporosis. This approach offers a promising, feasible strategy for managing musculoskeletal health and facilitating transition to sustainable exercise.

ID 1996- The influence of inflammatory and fibrotic markers on atrial fibrillation development in patients with arterial hypertension

Yu-Hsuan HAN, Ming-Hwai LIN

Department Of Family Medicine, Taipei Veterans General Hospital, Taipei, Taïwan

Context: Polypharmacy is a major challenge in home care, increasing risks of adverse drug events, readmission, and mortality. Existing medication review tools (e.g. the Medication Regimen Complexity Index (MRCI), Beers, STOPP/START, PIM-Taiwan) are often fragmented and time-consuming.

Objectives: This study aimed to develop an integrated medication optimization flowchart that incorporates these criteria and to evaluate the feasibility and effectiveness of using a Large Language Model (LLM) to implement this flowchart for home care patients with polypharmacy.

Methods: Home care patients with MRCI scores above 40 were included. Comprehensive medication lists were collected for each patient. A LLM (ChatGPT, GPT-5.1 model) was adapted using structured prompts and rule-based constraints to apply the Beers Criteria (2023), STOPP/START (v3), and PIM-Taiwan (2023). The AI generated prescribing suggestions, identified potentially inappropriate medications, and recommended potential omissions based on START criteria. AI-generated recommendations were reviewed by two family physicians and implemented when clinically appropriate. The MRCI scores were calculated pre- and post-intervention. Paired t-tests were conducted to assess the significance of changes in medication regimen complexity.

Results: A total of 26 patients (mean age: 86.3) were included. Participants had an average of 5.7 chronic diseases and used an average of 13 medications. The mean MRCI score decreased significantly from 48.29 ± 10.41 pre-intervention to 40.69 ± 11.05 post-intervention, representing a mean reduction of 7.6 points ($t(25) = -4.4$, $p < 0.001$). No adverse events related to deprescribing were reported during follow-up.

Discussion: The integrated flowchart demonstrated feasibility and efficiency in reducing medication regimen complexity. The LLM significantly improved the speed and consistency of applying multiple prescribing criteria, indicating its potential as a decision-support tool. However, AI outputs required mandatory clinician verification to mitigate risks of hallucination or misinterpretation. The focus was on simplifying regimens; the direct impact on clinical outcomes like readmission warrants future longitudinal studies.

Conclusion: This study introduces an AI-assisted integrated medication optimization flowchart that enhances rational prescribing and reduces polypharmacy in home care settings. The use of a LLM shows strong potential as a valuable decision-support tool in primary care, particularly in resource-limited environments. Further studies are warranted to assess clinical outcomes and scalability across different healthcare systems.

ID 1216- The Invisible Impact of Adolescent Obesity: A Primary Care Case Report

Zejdush TAHIRI

Ubt, Gjilan, Kosovo

Context: In post-war Kosovo, the magnitude of inappropriate use of benzodiazepines is unknown to date.

Objectives: The aim of this study was to assess the prevalence and correlates of continuation of intake of benzodiazepines beyond prescription (referred to as "inappropriate use") in the adult population of Gjilan region in Kosovo.

Methods: A cross-sectional study was conducted in Gjilan region including a representative sample of 780 individuals attending different pharmacies and reporting use of benzodiazepines (385 men and 395 women; age range 18–87 years; response rate: 90%). A structured questionnaire was administered to all participants inquiring about the use of benzodiazepines and socio-demographic characteristics.

Results: Overall, the prevalence of inappropriate use of benzodiazepines was 58%. In multivariable-adjusted models, inappropriate use of benzodiazepines was significantly associated with older age (OR 1.7, 95% CI 1.1–2.7), middle education (OR 1.8, 95% CI 1.2–2.7), daily use (OR 1.4, 95% CI 1.1–2.0) and addiction awareness (OR 2.7, 95% CI 2.0–3.8). Furthermore, there was evidence of a borderline relationship with rural residence (OR 1.2, 95% CI 0.9–1.7).

Discussion: The main finding of this cross-sectional study conducted in Kosovo consists of a high prevalence of inappropriate use of benzodiazepines. Independent correlates of inappropriate use of benzodiazepines included older age, middle education, daily use of these drugs and addiction awareness. Also, there was a hint for an association with rural residence.

Conclusion: Our study provides novel evidence about the prevalence and selected correlates of inappropriate use of benzodiazepines in Gjilan region of Kosovo. Health professionals and policymakers in Kosovo should be aware of the magnitude and determinants of drug misuse in this transitional society.

ID 1860- The Last Breath: A Family's Reckoning with Death

Jeanne LANG, Camille LAVRIL

Co Author, Paris, France

Context: Point-of-care ultrasound (POCUS) in primary care is expanding, but the level of scientific evidence remains limited. In the absence of international guidelines, this systematic review relies on several expert consensus statements and identifies ten main indications: confirmation of early intrauterine pregnancy, cholecystitis, cholelithiasis, intra-abdominal fluid, hydronephrosis, bladder volume assessment, abdominal aortic aneurysm, deep vein thrombosis, pleural effusion, subcutaneous abscess or foreign body.

Objectives: To evaluate the scientific evidence available in the literature supporting the expert-based indications for POCUS in general practice.

Methods: Systematic literature review following Cochrane methodology and PRISMA guidelines. The study was registred in PROSPERO. Searches were conducted in PubMed, Scopus, and Cochrane databases, including studies assessing POCUS in general practice between 2015 and 2025. Two independent reviewers screened eligible articles, extracted data using a standardized form, and assessed study quality using ROBINS-I v2 and QUADAS-2 tools.

Results: Of the 2985 articles sorted by title and abstract, 2919 were excluded. Of the 66 articles selected for full text reading, 61 were excluded and 5 prospective diagnostic or interventional studies were included (two on deep vein thrombosis, one on abdominal aortic aneurysm, one on abdominopelvic ultrasound, one on cutaneous abscess). Reported sensitivity of POCUS ranged from 69% to 98% and specificity from 95% to 99%. Cohen's kappa exceeded 0.80 in two studies. Three studies had a low risk of bias, while two showed high risk.

Discussion: The main strength of this study is that the selected articles concerned different

countries, a large number of patients and are contemporary, which reinforces the external validity. The limit was due to the heterogeneity of the articles, which did not allow a meta-analysis to be made.

Conclusion: Three high-quality studies confirm the reliability of POCUS for selected major indications in general practice. However, evidence remains limited for other applications. POCUS appears to be a promising tool in primary care, but further research is needed to strengthen the level of evidence.

Aix Marseille Universite, Marseille, France

Context: Context and objectives: In France, the number of practicing gynecologists is declining.Midwives and general practitioners are authorized to provide gynecological care, but this remains uncommon among them, leading to delays and gaps in care. Midwives and general practitioners are authorized to provide gynecological care,but this is rarely practiced by the latter, leading to delays andgaps in patient care. The objective of this study was toevaluate the gynecological practice of general practitioners working in the PACA regionand to identify the factors that may influence it.

Objectives: The objective of this study was toevaluate the gynecological practice of general practitioners working in the PACA regionand to identify the factors that may influence it.

Methods: Materials and methods: Quantitative, observational, descriptive, and cross-sectional study using a self-administered questionnaire.

Results: Results: The majority of respondents performed routine procedures such as HPV vaccination, prescribing contraception, and STI testing, while technical contraceptive procedures (insertion/removal of IUDs or implants) and cervical cancer screeningwere less commonly performed. For obstetric care, while initial pregnancy checkupswere often prescribed, few provided follow-up care until the seventh month. Femalegeneral practitioners who considered their initial training to be sufficient or who hadundergone additional training were more involved in gynecological and obstetric care.The main barriers identified were lack of The main obstacles identified were the lack of routine practice, the proximity of specialists, and lack of time. Conversely,recognition of the role of the general practitioner, personal conviction or interest, and the desire to diversify the patient base encouraged gynecological practice.

Discussion: Discussion: Better informing patients, promoting gynecological procedures, strengthening perinatal networks, raising awareness among male physicians, adapting initial training to private practice, and delegating certain tasks could encourage general practitioners to become more involved in gynecological practice.

Conclusion: Conclusion: Our results are consistent with studies conducted in other regions and shed light on the factors influencing the practice of gynecology by general practitioners in the PACA region, enabling us to propose strategies for improving gynecological care in general medicine.

Université De Namur, Namur, Belgique

Context: Our mentoring program has been defined as a "Pedagogical, support and exchange system between an experienced doctor (mentor) and the student (mentee) in a longitudinal (3 years) and non-hierarchical relationship, aimed at the professional empowerment of the mentee".The mentoring takes place in a friendly and non-hierarchical atmosphere with 4 meetings per year of

approximately 1.5 to 2 hours every 3 months during the 3 years of the mentee's assistantship.

Objectives: This is an interim evaluation of our mentoring program

Methods: Mentees' questionnaires were examined using a semi-quantitative approach, followed by an inductive thematic analysis of the open-ended responses. Mentors were assessed through a separate questionnaire."

Results: The results are very encouraging from both the mentees' and mentors' perspectives. The inductive thematic analysis highlighted seven main themes (the challenges of general practice residency, the organization of the internship, work–life balance, on-call duties, clinical cases, ethical issues, the final thesis, and professional relationships."). Four locations were identified where the meetings took place: the mentor's doctor's office, the mentor's home; a restaurant/café/bar; an outdoor or informal setting ("in a park," "during a walk," "in a garden," "during a bowling game"). Of the 27 students, only one did not complete all the meetings and was the subject of a separate analysis.

Discussion: Several potential pitfalls have been identified: mentor training and the method of forming mentor-mentee pairs. The deliberately encouraged informal framework for mentor-mentee meetings could lead to unstructured processes, but it remains a distinctive feature of our program.

Conclusion: Our interim evaluation after one year of operation is encouraging, even though many potential pitfalls have been identified. The specific features of our program, namely the three-year longitudinal follow-up of mentees and the informal framework of mentor-mentee meetings, still need to be precisely defined.

ID 831- The positive impact of an innovative welcome day on the mental health of first-year family medicine residents : a qualitative and quantitative study in East Occitanie.ie

Yaiza GIANZO [(1)], Iria CAUSÍN [(1)], Marc PERARNAU [(2)]

(1) Cs La Calzada, Gijón, Espagne
(2) Cs La Calzada, Barcelona, Espagne

Context: A 64-year-old man with poorly controlled hypertension and long-term smoking presented after a sudden, brief loss of consciousness triggered by laughter. Episodes were identical to two previous events years earlier. He experienced no prodromes, chest pain, palpitations, or dyspnea, and recovered fully within seconds. Examination and initial tests, including ECG, labs, and chest X-ray, were normal. The clinical picture suggested situational syncope, potentially laughter-induced ("gelastic syncope"), but cardiac causes required exclusion due to age and risk factors.

Methods: Assessment included detailed history, physical examination, and initial cardiovascular and neurological screening. Differential diagnoses considered reflex syncope, Valsalva-related situational syncope, arrhythmias, carotid sinus hypersensitivity, cataplexy, orthostatic hypotension, neurological disorders, and structural heart disease. Further recommended evaluations included Holter monitoring or event recording, echocardiography, and monitored carotid sinus massage, with consideration of tilt-table testing.

Originality: Laughter-induced syncope is an uncommon and often underrecognized entity within situational reflex syncope. Its reproducible emotional trigger, absence of prodromes, and abrupt onset make it a distinct clinical presentation, easily confused with neurological or cardiac disorders. This case highlights a rare but benign mechanism that contrasts with more typical vasovagal pathways.

Lessons learned and future implications: This case demonstrates the importance of exploring situational triggers when evaluating transient

loss of consciousness. Laughter can mimic a brief Valsalva maneuver, decreasing venous return and cerebral perfusion. Although reflex syncope is generally benign, older patients with cardiovascular risk factors warrant a systematic cardiac workup to rule out arrhythmogenic or structural disease. Increased awareness of laughter-induced syncope may prevent unnecessary investigations and reduce diagnostic uncertainty. Future research could clarify its prevalence and assess whether specific patient profiles—such as those with autonomic hypersensitivity—are predisposed.

Discussion: Laughter-induced syncope illustrates how everyday actions can provoke unexpected physiological responses. Recognizing emotional triggers enables clinicians to balance reassurance with targeted evaluation, avoiding misdiagnosis and unnecessary interventions.

Conclusion: The patient's presentation is most consistent with laughter-induced situational syncope, a rare form of reflex syncope. Despite its benign nature, appropriate cardiovascular evaluation remains essential in older individuals. Recognizing such unusual triggers helps refine diagnostic accuracy and supports personalized patient counseling

Context: Humanization in Primary Care is a wholistic and collaborative process in which all members of the multidisciplinary team—physicians, nurses, administrative staff, social workers, and other professionals—contribute to providing care that is proximate, more dignified, and person-centered. This approach recognizes that the quality of care depends on the coordinated interaction of diverse roles and competencies, particularly when addressing the needs of vulnerable populations. Within this framework, the SER+HUMANO (BE MORE HUMAN) strategy was developed to strengthen a culture of humanization through shared responsibility across the entire team.

Methods: The SER+HUMANO strategy was implemented in a Primary Care center with the goal of highlighting the contribution of all professionals and improving the overall patient experience. The initiative focused on promoting personalized care, enhancing communication and support for vulnerable groups, improving physical spaces to foster citizen well-being, and promoting the emotional and professional health of the team. Additionally, shared leadership and partnerships with local institutions were encouraged. After one year of implementation, adult patient satisfaction increased by 8%, complaints about inadequate treatment were reduced to zero, and perceptions of reception and accompaniment improved significantly, especially among older adults and individuals with communication difficulties. Identified limitations included the need for continuous evaluation and the importance of maintaining institutional commitment to ensure sustainability.

Originality: This project stands out for embedding humanization as a transversal axis across all professional roles, going beyond the traditional focus on the physician–patient relationship. It introduces a systemic approach in which every interaction—clinical, administrative, or social—contributes to truly person-centered care.

Lessons learned and future implications: Shared responsibility and effective communication among professionals were key to fostering trust, cohesion, and comprehensive responses. Future lines of work include consolidating impact indicators and expanding the model to other health centers.

Discussion: The experience shows that humanizing care does not mean adding tasks, but rather transforming the organizational culture by recognizing the value of each role within an integrated and empathetic approach.

Conclusion: Embedding humanization as a structural axis in Primary Care enhances satisfaction, accessibility, and respect in patient relationships, while strengthening teams committed to more inclusive, compassionate, and sustainable care.

Aušrinė JACKEVIČIŪTĖ [(1)] , Monika JUKONĖ [(2)]

(1) Faculty Of Medicine, Vilnius University, Vilnius, Lituanie
(2) Vilnius University Hospital Santaros Klinikos, Vilnius, Lituanie

Context: LHON is characterized by mitochondrial deoxyribonucleic acid (mtDNA) point mutations that lead to retinal ganglion cell degeneration and acute, progressive visual loss. In rare instances, referred to as LHON plus, additional systemic manifestations might occur, including peripheral neuropathy, ataxia, myopathy, or cardiac arrhythmias.

Methods: We report a male patient who first experienced mild visual impairment at 12 years of age. After two decades, his vision deteriorated over several months, resulting in the complete loss of reading ability. At age 45, he developed gait ataxia, lower limb paresthesia, foot pain, and left palm muscle atrophy. After extensive examinations, mtDNA sequencing detected two mitochondrial mutations, while electroneurography confirmed chronic sensorimotor axonal polyneuropathy. Based on these findings, a diagnosis of LHON plus was established.

Originality: Genetic analysis identified the m.8836A>G mutation, which has been reported in sporadic cases of LHON. Moreover, another mutation, m.9957T>C, typically linked to recurrent focal neurological deficits, seizures, headaches, and myopathy (MELAS syndrome), was also detected. The coexistence of these mitochondrial mutations has not been previously documented. The combination of this unique genotype and peripheral nerve involvement represents an atypical case of LHON.

Lessons learned and future implications: The coexistence of two mtDNA mutations might synergistically worsen mitochondrial dysfunction, broadening the phenotype from isolated optic neuropathy to systemic LHON plus. Comprehensive mtDNA sequencing should be performed in patients with an atypical clinical course.

Discussion: Our patient was treated with idebenone, vitamin E, alpha-lipoic acid, and creatine monohydrate for mitochondrial and neuroprotective support, alongside pregabalin and ongoing rehabilitation. Neuromuscular symptoms showed notable recovery, though visual improvement was temporary. Some studies report reversal of visual loss in patients treated during the acute stage, mainly in those harboring the more prevalent m.14484T>C mutation. These findings underline the potential role of genotype in determining therapeutic response.

Conclusion: LHON plus is often misdiagnosed and mismanaged due to its low prevalence in the population (<1:1 000 000). Despite limited treatment options, early diagnosis and prompt mitochondrial-targeted therapy might slow disease progression or partially restore function. Long-term multidisciplinary management is vital to preserve quality of life.

ID 601- The Quiet Rebellion: Storytelling as a Tool for Healing in Burnout Recovery

Juan Carlos TOMAS LÓEZ, Eugenia Del Rocio RIVERA TELLO, Hector Raul VARGAS SANCHEZ, Elizabeth GUZMAN MEDINA

Mexican Social Security Institute, Mexico, Mexique

Context: The Mexican Social Security Institute (IMSS) is the largest healthcare institution in Mexico. It has 54 million beneficiaries, of whom 5.3 million are diagnosed with diabetes. The

target for fasting glucose control is at least 40% (fasting plasma glucose between 70 and 130 mg/dL).

Methods: One of the potential causes for not achieving the control target is therapeutic inertia, which is present in a certain proportion of primary care physicians. To identify therapeutic inertia, the IMSS Family Medicine Division developed an evaluation tool, consisting of a retrospective review of medical records to identify the therapeutic adjustments made by physicians in the last 6 months of care. During 2024, the tool was implemented in 1,250 Family Medicine Units nationwide, through department heads or unit directors.

Originality: The following results were identified: More than 12,000 patient records were reviewed each month. The results were analyzed quarterly In the first quarter, 47% of patients underwent therapeutic adjustments, increasing to 64% in the last quarter of 2024, with an annual average of 55.7%. The average for the first half of 2025 was 63%.

Lessons learned and future implications: There is therapeutic inertia in primary care, so mechanisms will be established to easily identify it and provide feedback to physicians. The implementation of Pharmacological Control facilitated adjustments to the pharmacological treatment of patients with diabetes, improving glycemic control. At the Mexican Social Security Institute (IMSS), this tool will continue to be implemented in Family Medicine Units, and training for primary care physicians on making therapeutic adjustments for diabetes will continue.

Discussion: It is possible to create agile monitoring and evaluation tools for primary care medical staff to advise and change pharmacological prescribing behaviors, for the benefit of patients

Conclusion: It is important and necessary to create tools to identify therapeutic inertia in primary care physicians, to provide guidance and change prescribing behavior in order to improve metabolic control in persons living with type 2 diabetes

Corresponding author: Juan Carlos Tomas Lóez, tomljc80@yahoo.com.mx

ID 2183- The Relationship Between Family Physicians' Burnout and Patient-perceived Psychosocial Support in Primary Care

Juan Carlos TOMAS LÓEZ, Eugenia Del Rocio RIVERA TELLO

Mexican Social Security Institute, Mexico, Mexique

Context: Diabetes management requires the control of several metabolic and physiological indicators. Family factors influence metabolic control in persons living with diabetes.

Objectives: To determine the difference in family cohesion and adaptability between patients with controlled type 2 diabetes and those with uncontrolled diabetes.

Methods: Design: Observational, retrospective, cross-sectional, descriptive, and comparative. Materials and Methods: 147 patients with type 2 diabetes mellitus attending the outpatient clinic of a Family Medicine Unit were included. A survey on metabolic control and the FACES III questionnaire for family cohesion and adaptability were administered.

Results: A total of 147 patients were interviewed: 71 uncontrolled patients (48.3%) and 76 controlled patients (51.7%). Among patients with metabolic control, the following family cohesion patterns were found: Unrelated: 72.36%, Semi-related: 15.78%, Related: 6.66%, and Enmeshed: 5.26%. Family adaptability patterns were: Rigid: 1.31%, Structured: 9.21%, Flexible: 3.94%, and Chaotic: 85.54%. Among patients with poor metabolic control, the following family cohesion patterns were found: Unrelated: 85.93%, Semi-related: 7.04%, Related: 1.40%, and Enmeshed: 5.63%. Family adaptability patterns were: Rigid: 12.67%, Structured: 1.40%, Flexible: 9.85%, and Chaotic: 76.08%. For family cohesion, a chi-square value of 5.39 was obtained; $p = 0.020$. For family adaptability: chi-square value of 0.12; $p = 0.726$.

Discussion: Families with diabetic patients tend toward extreme cohesion, which is significantly accentuated in those with metabolic

dysregulation, who are more frequently classified as unrelated families. Patients with metabolic dysregulation tend to have more rigid family structures compared to the group with metabolic control.

Conclusion: Therefore, a lack of cohesion and family rigidity could influence metabolic dysregulation in patients with type 2 diabetes. There is no conflict of interest. The study was submitted for evaluation by the local ethics committee.

ID 1634- The Relationship between TyG Index and Comorbidity of Diabetes and Hypertension in the old adults

Gabriela PATIÑO MURILLO

Primary Care, Ávila, Spain, Avila, Espagne

Context: Hypertension is one of the most common chronic conditions managed in primary care, yet blood pressure control remains suboptimal despite evidence-based guidelines. Institutional digital tools, including electronic health records and shared clinical platforms, are routinely used and may support continuity, safety and equity in hypertension follow-up. However, little is known about how primary care professionals perceive these tools in everyday clinical practice, and no qualitative studies have explored perceived usefulness, ease of use or barriers related to these systems in this primary care context.

Objectives: Primary objective: To explore primary care professionals' perceptions of institutional digital tools used in the follow-up of patients with hypertension. Secondary objectives: To identify barriers and facilitators influencing their use, examine how these tools are integrated into daily workflows, and explore expectations for future digital solutions.

Methods: This ongoing qualitative exploratory study is being conducted in primary care centres in a non-specified region (XXX). Semi-structured interviews are carried out with family physicians, residents, nurses and nursing residents who routinely use institutional digital tools. Purposive sampling ensures variation in experience, professional role and practice setting. Interviews are audio-recorded, transcribed verbatim and analysed using thematic analysis. A deductive–inductive approach is applied: the Technology Acceptance Model guides initial coding while allowing additional themes to emerge. Credibility is ensured through investigator triangulation and documentation of analytic decisions. Data collection and analysis will be completed before the conference.

Results: Anticipated themes include: – Perceived usefulness: better organisation of clinical information and support for timely follow-up. – Perceived ease of use: varied experiences related to system usability, navigation and consultation time. – Barriers: technical issues, interoperability limitations, administrative burden and structural constraints in some settings. – Facilitators: familiarity with the system, routine integration and rapid access to relevant data. – Equity considerations: digital literacy gaps and unequal patient access to digital resources. Final thematic categories will be presented at the conference.

Discussion: Preliminary insights suggest that digital tool adoption is shaped by technological, organisational and human-factor elements, highlighting both strengths and areas for improvement within primary care.

Conclusion: Understanding professionals' perceptions can inform more human-centred, equitable and effective digital strategies for hypertension management in primary care.

ID 234- The Relationship of Body Mass Index and All-Cause Mortality: Mediation by Left Ventricular Mass

Tania RUBAIYYAT, Jamie WICKETT, George KIM

Western University, London, Canada

Context: International medical graduates (IMGs) are a cohort of family medicine residents who have done their medical degree outside of XXX. Due to the heterogeneous

medical degree background of IMGs, one might wonder if IMGs have a different experience in receiving feedback compared to their XXX trained counterparts.

Objectives: The objective of this qualitative research study was to explore and describe the experience of recent IMG resident graduates' experience in receiving feedback during their Family Medicine training at Western University.

Methods: A qualitative descriptive design using Iterative and interpretative analysis techniques was used. A semi-structured interview guide was used.

Results: Three distinct themes were noted. The first theme was the meaning of feedback. The logistics of feedback was the second theme - four sub-themes 1) type and timing of feedback; 2) delivery of the feedback (who and how); 3) resident-initiated feedback and 4) evolution of feedback throughout residency. The final theme was experience with feedback: two sub-themes- 1) experience with positive feedback and 2) experience with negative feedback.

Discussion: All participants agreed the purpose of feedback is to address areas of improvement with the goal of improving overall performance. Both formal and informal feedback were received. They received feedback mostly from their core FM supervisors. Most feedback occurred face to face. Usually, most of the feedback is initiated by the supervisor. In this study, residents have initiated the feedback to comprehend the expectations of that rotation. Over the residency, residents did not notice any change in the frequency of formal feedback. Informal feedback became less frequent. Residents received positive and negative feedback in a wide variety of areas. Positive feedback boosted their confidence while negative feedback made them to question their ability and affected performance negatively.

Conclusion: This study provided an enhanced understanding of the experience of IMG residents in receiving feedback during FM residency, which can be used by the Postgraduate program in reviewing the way in which feedback is delivered to IMG residents.

ID 915- The role of acupuncture in general medicine: between preconceptions and recommendations

Sarah Lou MAMOUNE, Benjamin BASTIAN, Karl BEAUFRETON, Eric MENER

Université De Rennes, Rennes, France

Context: The practice of hypnosis in general medicine is widespread in XX. While several studies have documented patients' positive experiences during and shortly after hypnotherapy, the long-term persistence of these therapeutic benefits remains insufficiently explored.

Objectives: Explore patients' experiences one year after specific hypnotherapy in general practice in XX.

Methods: Qualitative study conducted through semi-structured interviews with adult patients of five general practitioners trained in the same method of hypnosis. Participants had received 3 to 6 therapy sessions completed 12 to 15 months prior. The interview guide was developed in collaboration with several hypnotherapy experts. A thematic analysis was performed on verbatim transcripts after double independent coding. The external validity and methodological rigor were assessed using the COREQ checklist.

Results: Eleven interviews were conducted between May and July 2021, until data saturation was reached. Patients reported an overall positive therapeutic experience, with perceived benefits persisting one year later. Hypnosis was perceived as a therapeutic tool that promoted self-awareness, increased self-confidence, and improved symptom self-management skills. The therapeutic alliance was identified as a key factor. The main obstacle mentioned was the financial cost of the therapy.

Discussion: A key strength of this study is the inclusion of patients treated with the same hypnotherapy method. Hypnosis appears to be a relevant within a person-centered model of care. It enables patients to gain a better

understanding of their illness and become more autonomous in dealing with it. However, the lack of analysis of external factors may limit the interpretation of the results.

Conclusion: Patients reported a positive experience with concrete changes in their daily lives that were still evident one year later. They embraced it as a real therapeutic education tool, with half of the patients practicing self-hypnosis. These findings support the need for further research into the effectiveness and potential indications of hypnotherapy in primary care.

ID 1770- The role of general practitioners in Mass gatherings events

Marloes MINNAARD [(1)], Stuart HOLMES [(2)] , Rianne VAN VLIET [(3)]

(1) Staff Member, Utrecht, Pays-Bas
(2) General Practitioner, Manchester, Royaume-Uni
(3) General Practitioner, Den Haag, Pays-Bas

Context: General practitioners (GPs) working in prisons operate within a healthcare environment that diverges substantially from community practice. Prison consultations are shaped by collaboration with prison authorities, disciplinary measures such as solitary confinement, and the legal frameworks underpinning access to medical care for incarcerated individuals. Compared to the general population, prisoners demonstrate markedly higher prevalence of substance use disorders, psychiatric illnesses, and intellectual disabilities, creating complex challenges for primary care delivery. The European Forum for Primary Care position paper (2022) emphasizes the critical role of primary care in addressing detainees' complex health needs and ensuring continuity of care.

Objectives: To understand the legal and organizational principles of prison healthcare, using the Netherlands and UK as examples. To identify systemic and clinical differences between prison consultations and community practice. To explore the prevalence and complexity of health problems in prison populations. To compare challenges internationally and evaluate potential solutions. To define the scope of influence of GPs in prison healthcare systems.

Teaching method and workshop: The workshop will employ interactive group work, case-based discussions, and structured reflection. Participants will identify bottlenecks, compare them across countries, and identify feasible interventions. Facilitators will emphasize active engagement a

Expected outcomes: Participants will gain insight into prison healthcare systems, improve confidence in managing complex patient needs, and recognize interventions within their professional scope versus those requiring systemic change.

Conclusion: Prison healthcare presents distinctive challenges but also opportunities for innovation and collaboration. By sharing experiences internationally, participants will strengthen patient-centered care in prisons and advocate for systemic improvements. This workshop contributes to WONCA's mission of advancing primary care globally, while aligning with WHO recommendations on equivalence of care and the European Forum for Primary Care's call for stronger integration of prison health into mainstream primary care.

Corresponding author: Marloes Minnaard, mc_minnaard@hotmail.com

ID 2271- The Role of Lifestyle Medicine in Family Medicine: Structured Debate and Vision-Building.

Danijela TODOROVIĆ GRBIĆ

Jzu Dom Zdravlja Kozarska Dubica, Prijedor, Bosnie-Herzégovine

Context: Family physicians often deeply intertwine their sense of identity with constant responsibility and service to patients. Because of this, the transition into retirement can be psychologically challenging. Retired or near-retirement doctors may experience anxiety, loss of purpose, and fear of becoming irrelevant. In such circumstances, some continue to work excessively, even beyond formal retirement, to preserve meaning, status, and routine. These patterns frequently remain

unrecognized in primary care systems, leaving physicians without adequate psychological or structural support.

Methods: A qualitative, reflective, case-based approach was used. The analysis focuses on a 66-year-old retired family physician who continues to work up to 20 shifts per month in both primary care and hospital settings. The case was interpreted using psychological frameworks related to work addiction, perfectionism, existential anxiety, and the need for control. The reflection examines behavioral patterns, emotional drivers, and environmental factors that contribute to persistent over-engagement in work after retirement.

Originality: Work addiction in physicians, especially after retirement, is an under-explored topic. This case highlights how identity loss—not financial motives—is often the central mechanism behind continued excessive work.

Lessons learned and future implications: This case demonstrates that retirement transitions require psychological preparation, not only administrative planning. Without structured support, physicians may remain trapped in unhealthy work patterns driven by fear of losing identity. Future healthcare strategies should include mentorship opportunities for retired doctors, gradual reduction of workload, psychological counseling, and improved awareness of work addiction within the medical profession.

Discussion: The presented case suggests that persistent work engagement after retirement reflects a coping mechanism rather than a continued professional duty. The doctor's behavior aligns with features of work addiction—compulsion, inability to disengage, and emotional dependence on professional roles. Primary care physicians often tie their self-worth to their usefulness, making retirement psychologically destabilizing. This highlights systemic gaps: insufficient emotional support, lack of transition planning, and a culture that rewards self-sacrifice.

Conclusion: Work addiction and identity loss among retired physicians are real but frequently overlooked issues. Recognizing these patterns is crucial for building healthier retirement pathways. Structured interventions—education, counseling, mentorship roles, and gradual withdrawal from clinical duties—can help physicians navigate identity changes while maintaining well-being.

ID 723- The Role of Point-of-Care Ultrasound (POCUS) in Community and Home Care

Alejandra MAY MOTA, Mercedes RETANA PUIGMARTÍ, Zully AMAYA CARRERA, Darío MARTÍN MORERA, Esteban VICIANA NIETO, Katia QUISPE MUNARRIZ

Camps Blancs-Primary Care Center, Instituto Catalán De La Salud, Sant Boi De Llobregat., Barcelona, Espagne

Context: Given the increase in international migration, the health assessment of immigrant patients should be considered comparable to that of native-born patients, while incorporating specific considerations such as inclusion in preventive care and health-promotion programs, screening for imported diseases (according to country of origin and migration route), and assessment and adaptation of immunization status to the vaccination schedule in effect in the host country.

Methods: The patient is a 38-year-old woman, originally from XXX , residing in XXX for the past year. She is married and heterosexual. She denies engaging in high-risk sexual practices and reports no history of blood transfusions or intravenous drug use.

Originality: Six months after arriving in XXX, she attended her family physician for an initial consultation due to longstanding asthenia. She reported that, during the previous year in her country of origin, she had experienced multiple illnesses, including upper respiratory tract infections, pneumonia, episodes of diarrhea, and three episodes of oral candidiasis. These conditions were managed symptomatically, without further diagnostic evaluation. The patient also stated that access to healthcare in her hometown is limited. The patient's physical examination revealed no significant findings.

General blood tests showed lymphopenia, abnormal liver function tests, and positive HIV 1-2 antibodies and p24 antigen.

Lessons learned and future implications: Upon identification of human immunodeficiency virus (HIV), the patient is referred to the infectious diseases department at the designated tertiary care hospital, where she will initiate appropriate antiretroviral therapy. The transmission route was determined to be sexual. The patient is currently well controlled. It is important to underscore the differences in health equity across countries. According to the World Health Organization in 2025, the gap in life expectancy between nations may reach up to 33 years.

Discussion: Primary care physicians play a crucial role as the first point of contact with the healthcare system, allowing early identification of risk factors, timely diagnostic evaluation, and initiation of appropriate management.

Conclusion: Early diagnosis enables prompt initiation of antiretroviral therapy, providing both individual benefits—reducing morbidity and mortality—and collective benefits by interrupting the chain of transmission, making early detection in primary care essential for public health. Keywords:HIV infections, primary health care, immigrants, health equity.

Corresponding author: Alejandra May Mota, ale_28@hotmail.com

ID 637- The Role of Primary Care in Breast Cancer Screening

Alejandra MAY MOTA, Mercedes RETANA PUIGMARTÍ, Zully AMAYA CARRERA, Darío MARTÍN MORERA, Katia QUISPE MUNARRIZ, Esteban VICIANA NIETO

Camps Blancs-Primary Care Center, Instituto Catalán De La Salud, Sant Boi De Llobregat., Barcelona, Espagne

Context: Lower back pain is one of the most common reasons patients visit primary care physicians. The Ministry of Health recognizes it as a significant public health issue due to its high prevalence and the substantial healthcare costs it imposes.

Methods: 70-year-old patient. Retired nurse. Medical history: benign prostatic hypertrophy. Three-month history of progressively worsening lower back pain, aggravated by physical activity, accompanied by asthenia. Self-medicated with first-step analgesics with partial improvement. Physical examination revealed moderate lumbar tenderness without radiculopathy and tenderness of the anterior wall of the left hemithorax. In light of the prolonged symptom duration, the patient's advanced age, and the presence of systemic manifestations, further diagnostic investigations were undertaken. Laboratory findings: normocytic-normochromic anemia, renal failure, hypercalcemia. Imaging tests: lumbosacral spine X-ray: no apparent alterations. CT scan : mass in the upper left chest wall, with lysis of the anterolateral region of the left third rib, measuring 7 x 4.4 cm in the axial plane. Several vertebral and sternal lytic lesions, the most evident of which was the vertebral transverse process (T8). Grade II compression fracture of T4. Lytic lesions of the sternum.

Originality: The combination of chronic back pain, anemia, renal dysfunction, hypercalcemia, and multiple lytic bone lesions suggests multiple myeloma with skeletal involvement. The patient was finally diagnosed with IgA kappa IIIA Durie-Salmon/International Staging System II multiple myeloma with treatment criteria for bone lesions.

Lessons learned and future implications: One of the common presentations of multiple myeloma is bone pain, which can be mistaken for other degenerative skeletal conditions, potentially delaying diagnosis. There is a Cochrane database review on "Red flags to screen for vertebral fracture in people presenting with low back pain" that may be useful in our practice.

Discussion: This case underscores the importance of careful evaluation of elderly patients with new-onset back pain and systemic symptoms, highlights early recognition of red flags, and emphasizes the role of primary care physicians in initiating timely investigations and coordinating management for serious underlying conditions.

Conclusion: The primary care physician plays a crucial role in the early diagnosis of multiple myeloma, thereby contributing to improved survival and quality of life. Keywords: multiple myeloma, hypercalcemia, low back pain.

Corresponding author: Alejandra May Mota, ale_28@hotmail.com

ID 1225- the role of primary care physicians in humanitarian aid to disaster zones

Pedro CARDOSO, Sandra CRUZ, Conde INÊS, Ferreira JOANA

Unidade Local De Saúde De Trás-Os-Montes E Alto Douro, Vila Real, Portugal

Context: Energy poverty—difficulty achieving adequate indoor thermal comfort—has been consistently linked to poorer mental health. Yet the effects of corrective interventions on validated mental-health outcomes remain unclear

Objectives: Quantify the impact of interventions that reduce energy poverty (fabric insulation, draught-proofing, central-heating, whole-house packages, and educational advice) on validated mental-health outcomes versus usual care/no intervention or alternative interventions.

Methods: We registered a protocol (PRISMA 2020) and searched MEDLINE/PubMed, Embase, Scopus, Web of Science, CENTRAL, PsycINFO, CINAHL and grey sources (2005–2025). Eligible studies evaluated interventions targeting thermal comfort/affordability (fabric insulation, heating systems, whole-house retrofits, behavioural advice) and reported validated mental-health outcomes (e.g., GHQ-12, SF-12/36 MCS, HADS/PHQ/GAD). We included randomised and non-randomised comparative designs and undertook random-effects meta-analyses by intervention class where ≥3 comparable estimates were available; otherwise, we applied SWiM narrative synthesis. Risk of bias was assessed with RoB 2/ROBINS-I; certainty with GRADE.

Results: Eight intervention studies met criteria (United Kingdom n=6, New Zealand n=1, Portugal n=1), including one cluster RCT and seven non-randomised evaluations. Structural fabric upgrades and heating/system improvements were most common; purely behavioural/educational interventions were rare. Pooled effects (GHQ-12/SF-12 MCS) suggested small but clinically meaningful improvements in psychological distress/mental health following fabric upgrades and combined packages; system-only upgrades showed modest, directionally similar gains. Heterogeneity was moderate, reflecting differences in intervention bundles, populations and instruments. Subgroup evidence—limited but consistent—indicated larger benefits among more deprived households and those with poorer baseline thermal performance. Cost-effectiveness analyses (mainly UK) favoured insulation/heating upgrades when mental-health gains and co-benefits were included. Overall risk of bias was “some concerns” (cRCT) and “moderate–serious” (non-randomised) due to confounding, selection and self-report; GRADE certainty was low to moderate.

Discussion: Energy-efficiency retrofits—especially insulation combined with controllable heating—yield modest, consistent improvements in GHQ-12 and MCS, likely mediated by thermal comfort and reduced bill stress. Benefits appear larger in the coldest, most deprived homes. Evidence remains constrained by bias and heterogeneity; stronger, longer studies with objective mediators and economic evaluation are priorities.

Conclusion: Energy-efficiency retrofits—especially insulation and central-heating packages—likely improve mental-health outcomes, with equity-relevant gains in high-need groups. Stronger evidence is needed from well-designed RCTs/quasi-experiments using standardised mental-health measures, longer follow-up and cost-utility endpoints, particularly beyond the UK.

Context: Rhinitis is highly prevalent across all ages, significantly impairing the quality of life of patients and their cohabitants. Underdiagnosis and misdiagnosis are common, leading to under or inappropriate treatment, negative economic impact, and potential harm. Most people manage it episodically, through self-management or OTC medications. Many underestimate their symptoms, not bringing them to the attention of their family physician. Allergic rhinitis (AR) is strongly associated with an increased risk of developing asthma often due to sensitisation to multiple allergens. Those with AR are more likely to have frequent asthma exacerbations and poorer symptom control than those with asthma alone. Managing allergic rhinitis well in primary care is also an important opportunity to take a One Health approach, protecting patients from environmental changes and protecting the planet from inappropriate medicines use.

Objectives: This workshop will discuss primary care-derived person-centred cases on diagnostic and management challenges in rhinitis. Participants will explore practical, evidence-informed strategies to improve recognition, shared decision-making, and sustainable management of rhinitis within the broader context of respiratory and planetary health.

Teaching method and workshop: After a short introduction, participants will engage in group work using clinical vignettes. The faculty will facilitate discussions introducing practical tools. A voting system will support interaction. These free tools were co-produced by primary care c

Expected outcomes: Participants should be able to a) List some challenges in the diagnosis and management of Rhinitis; b) Assess the impact of patients' symptoms considering their ideas, concerns, and expectations; c) Consider a diagnosis of asthma as the most important com

Conclusion: Rhinitis is a risk factor for the development of asthma and is often associated with poorer asthma control and reduced patient quality of life. Enhancing primary care with person-centred, environmentally responsible approaches can improve patient and planetary outcomes.

ID 542- The School as a Territory of Care: Medical Education Building Bridges for Health Education on Electronic Cigarettes among Students

Jennifer NEIL [(1)] , Clare DELANY [(2)], Elizabeth MCLINDON [(1)], Kelsey HEGARTY [(1)]

(1) Department Of General Practice And Primary Care, The University Of Melbourne, Melbourne, Australie
(2) Department Of Medical Education, The University Of Melbourne, Melbourne, Australie

Context: Domestic and family violence (DFV) is very common worldwide with one in four women being subjected to intimate partner violence and one in two adults being survivors of child abuse. General practitioners (GPs) are not immune from being affected by DFV. GPs are unique in that they manage whole families with longitudinal, comprehensive care. Yet, people who use DFV, (most commonly, but not exclusively, men) are more likely to attend their GP than people who don't use DFV, meaning that GP survivors of DFV will encounter them in their clinics.

Objectives: What are the experiences of survivor GPs when working with people who use DFV?

Methods: This study used a phenomenological qualitative approach to gain a deep understanding of [country] GP DFV survivors' experiences when working with people who use DFV, whether it be a patient or a parent/carer of a patient who is being abused.

Participants were [country] GPs who self-identified as survivors of all forms of DFV. Purposive sampling was used to recruit participants from two [country] GP online groups. Semi-structured interviews took place and were audio recorded and transcribed verbatim. Reflexive thematic analysis was undertaken.

Results: Participants (20) were female and worked in a range of locations throughout [country]. All participants worked with people who used DFV. Three themes were identified: Feeling unsafe; Unprofessional feelings; and tension in the relationship. Changes in the doctor/patient relationship were evident with multiple participants firing patients due to either feeling 'triggered' or feeling that they were unable to work with the patients or parents of abused children due to judgement, hatred or anger. These feelings were identified as a direct result of their own experiences of abuse.

Discussion: This is the first qualitative study investigating GP survivors' experiences working with people who use violence. There is little in the health professions literature on this topic. Survivor GPs would benefit from support when working with people who use DFV due to secondary re-traumatisation.

Conclusion: Survivor GPs would benefit from support when working with both people who use DFV and their families. Further research is recommended to investigate how best to support survivors GPs.

ID 1247- The Silent Stumble: Association Between Objective Sensory Impairment and Fall History Among Elderly Residents in Singapore Rental Housing

Jia Wen LIU, I Ren TAI

Cardinal Tien Hospital, New Taipei City, Taïwan

Context: Peptic ulcer disease (PUD) remains a frequent and clinically significant problem in both primary and acute care settings. Proton pump inhibitors (PPIs) have traditionally served as the cornerstone of therapy. Vonoprazan, a potassium-competitive acid blocker (P-CAB), has gained increasing use due to its rapid and sustained acid suppression, yet its advantages over PPIs in real-world clinical practice remain inadequately defined.

Objectives: To critically appraise recent evidence comparing vonoprazan with PPIs in the management of acute PUD, with a focus on ulcer healing, upper gastrointestinal (GI) rebleeding, adverse events, and cost-effectiveness from a primary care perspective.

Methods: A structured PubMed search identified 19 eligible studies published between 2019 and 2025, including randomized trials, cohort studies, meta-analyses, and network meta-analyses. Exclusion criteria included non-human studies, non-English publications, inconclusive results, and studies unrelated to peptic or duodenal ulcers. Extracted outcomes included ulcer healing rates, upper GI rebleeding, treatment-related adverse events, hospitalization duration, transfusion needs, and economic evaluations.

Results: Across studies, vonoprazan achieved ulcer healing rates that were consistently non-inferior and in some cases modestly superior to PPIs. Several East Asian real-world cohorts reported numerically lower short-term rebleeding rates with vonoprazan, though significance varied. Serious adverse events did not differ between groups, while minor gastrointestinal symptoms appeared slightly more common with vonoprazan but without clinical consequence. Economic analyses suggested potential cost-effectiveness for high-risk subgroups, although higher upfront drug costs limit widespread use. Mortality outcomes were low and showed no meaningful differences.

Discussion: Vonoprazan's potent acid suppression may offer clinical benefits in selected scenarios, particularly when rapid control is required or PPI response is suboptimal. However, the concentration of available evidence in East Asia and heterogeneity across studies limit broader generalization. For primary care physicians, treatment selection must balance clinical

efficacy with medication cost, patient comorbidity, and local practice patterns.

Conclusion: Vonoprazan offers potent and reliable acid suppression with efficacy and safety comparable to PPIs in acute PUD management. Although cost remains a limiting factor, it represents a reasonable therapeutic option in appropriately selected patients. Treatment choice should remain individualized, guided by clinical risk, treatment response, and healthcare system context.

Victoria AZAROV, Zsófia LÁZÁR

Semmelweis University, Budapest, Hongrie

Context: Acute exacerbations of chronic obstructive pulmonary disease (AE-COPD) are commonly first evaluated in primary care, where early identification of patients at risk of deterioration is essential. The pulmonary artery–ascending aorta (PA/A) ratio on chest CT has been proposed as a non-invasive marker of pulmonary hypertension and adverse outcomes in stable COPD, but its relevance during exacerbations and its importance for general practice remain unclear.

Objectives: To assess the inter-observer variability of PA/A ratio values and their associations to clinically relevant outcomes in patients hospitalized with AE-COPD.

Methods: We performed a retrospective study of adults hospitalized with a primary diagnosis of AE-COPD who underwent chest CT during hospitalization between 1 January 2020 and 31 March 2025. Two independent observers measured the PA/A ratio using standardized anatomical landmarks, and the mean of their measurements was used to categorize patients into two groups using the established cut-off of PA/A >1. Outcomes included length of hospital stay, need for non-invasive ventilation (NIV), and antibiotic treatment. Statistical analyses included Bland–Altman comparison, t-tests, and Fisher's exact tests.

Results: Of 174 patients screened, 35 met inclusion and exclusion criteria (16 males/19 females, mean age: 68.8 ± 8.4 years). All patients were treated with systemic corticosteroids. Interobserver analysis showed good agreement (bias: –0.01, 95% limits of agreement: –0.15 to 0.12) and no systematic difference was found (p=0.32). 20 patients had a mean PA/A ≤1 and 15 patients showed PA/A >1. Length of hospital stay did not differ between groups (10.9 vs 11.3 days, p=0.83) and antibiotic rates were comparable (65% vs 73%, p=0.72). However, NIV use was significantly higher in the >1 group (25% vs 67%, p=0.02).

Discussion: A PA/A ratio >1 was strongly associated with an increased need for NIV, suggesting value as an early indicator of exacerbation severity. For primary care clinicians, familiarity with this parameter may support triage decisions and improve interpretation of radiology reports from referrals.

Conclusion: PA/A ratio is a reproducible measurement and may help identify AE-COPD patients at higher risk of requiring respiratory support. Prospective studies in community-managed COPD populations are warranted to explore its role in guiding referral urgency and follow-up in primary care.

(1) Nowon Eulji Medical Center, Seoul, Corée (République de)
(2) Theragen Health Co. Ltd, Seongnam-Si, Corée (République de)

Context: Hypertension is a major risk factor for cardiovascular and renal diseases. Genome-wide association studies (GWAS) have identified numerous single nucleotide polymorphisms (SNPs) linked to hypertension. Specifically, the rs17249754 polymorphism in the ATP2B1 gene is implicated in blood

pressure (BP) regulation. The A allele is hypothesized to confer protection by influencing Ca2+ ion handling in vascular smooth muscle cells.

Objectives: This study analyzed the association between ATP2B1 rs17249754 and BP, focusing on interactions with smoking and alcohol consumption in a cohort.

Methods: A total of 65,535 participants from the Genome and Epidemiology Study were included. Genotyping, quality control, phasing, and imputation were performed using standard protocols. The target polymorphism, ATP2B1 rs17249754, was extracted using PLINK. Linear regression evaluated the associations with systolic and diastolic BP, stratified by lifestyle factors and adjusted for covariates.

Results: Linear regression analyses, adjusted for covariates such as sex, age, BMI, and lifestyle factors, revealed that individuals with the AA genotype exhibited significantly lower systolic (SBP) and diastolic blood pressure (DBP) compared to GA or GG genotypes. Lifestyle factors strongly influenced these genetic effects. Among smokers, current smokers with the AA genotype showed SBP reduction compared to GA or GG genotypes. Similar associations were observed among non-drinkers and current drinkers.

Discussion: The ATP2B1 rs17249754 polymorphism regulates calcium homeostasis via PMCA1, reducing vascular smooth muscle contraction and BP. Smoking and alcohol consumption might disrupt calcium regulation and increase oxidative stress, which could exacerbate BP dysregulation, particularly in GA or GG genotypes. Smoking cessation and reduced alcohol intake may help mitigate these effects, possibly allowing the A allele to play a protective role.

Conclusion: This study emphasizes the interplay between genetic and environmental factors in BP regulation, supporting the integration of genetic markers with lifestyle interventions for personalized hypertension management.

Hoon-Ki PARK, Hyojeong LEE

Hanyang Univrtsity College Of Medicine, Seoul, Corée (République de)

Context: The integrated curriculum aims to help students construct clinically meaningful knowledge. A systematic evaluation of content interconnection is necessary to assess its effectiveness. As curriculum autonomy has expanded following academic system reform, reviewing and refining each college's integrated curriculum has become increasingly important.

Objectives: This study aimed to evaluate the level of integration and operational status of the cardiovascular system block to prepare basic data for future curriculum evaluation and improvement.

Methods: We analyzed the cardiovascular system block delivered over four weeks (March 4–28, 2025) at Hanyang University. The course included 68 sessions (109 hours), which were conducted by 29 faculty members, and nine second-year students participated. The level of integration was assessed using three items scored on a 4-point scale. Scores were categorized as follows: Isolation (below 5), Initial (5 to under 8), Intermediate (8 to under 11), and Mature (11 to12). Students completed a survey after each session. Descriptive statistics were used, and a group interview was conducted after the course and qualitatively analyzed.

Results: The overall integration score of the cardiovascular system block was 8.60 (level of intermediate). The majority of sessions received an intermediate rating (n=48), followed by an initial rating (n=16) and a mature rating (n=1). No sessions received an isolation rating. Problem-based learning (PBL) and case-based teaching (CBT) had high integration scores (10.52 and 10.57). Students reported lower perceived integration when content or clinical cases were too detailed, rare, or broad.

Discussion: Reorganizing session order and using common clinical cases may enhance integration. For enhancing the overall integrated curriculum, future studies will compare faculty and student perspectives and explore integration in other system blocks.

Conclusion: The block showed moderate integration, but deeper content-level nesting—defined as the structural embedding of concepts across sessions—was limited. Deep learning methods, like PBL and CBT, augmented integration.

Yu Hyeon YI

Department Of Family Medicine, Pusan National University School Of Medicine, Yangsan, Korea; Department Of Family Medicine, Pusan National University Hospital, Busan, Korea, Busan, Moldova (République de)

Context: Despite major advances in lung cancer diagnosis and treatment, substantial geographic and socioeconomic disparities in survival remain worldwide. In Korea—where universal health coverage and national cancer screening programs are established—regional inequalities persist, suggesting an important role of contextual socioeconomic conditions. The Regional Deprivation Index (RDI) provides a multidimensional measure of structural deprivation that may explain spatial variations in outcomes.

Objectives: To investigate temporal trends and regional differences in lung cancer survival across Korea from 2003 to 2020, and to quantify the contribution of contextual deprivation to survival inequalities.

Methods: We analyzed data on 29,065 individuals newly diagnosed with lung cancer using the Korean Regional Cancer Registry. Survival outcomes were estimated using multilevel frailty survival models that incorporated individual-level clinical and demographic factors alongside regional-level characteristics. Contextual deprivation was measured using the RDI, a composite indicator comprising nine socioeconomic dimensions: housing environment, education, social class, elderly population share, single-person households, car ownership, housing type, household composition, and marital status. Empirical Bayesian estimation was applied to generate smoothed spatial survival estimates and to visualize variations by year, sex, age group, and cancer stage.

Results: Between 2003 and 2020, overall survival improved from 41.4% to 67.9%. However, persistent and substantial regional disparities remained throughout the study period. Each one-point increase in the RDI was associated with an approximately 3.9% decrease in survival probability. After adjusting for individual and contextual characteristics, regional heterogeneity was reduced by nearly one-third, indicating that contextual deprivation meaningfully contributed to spatial inequalities. More deprived regions consistently demonstrated lower 1-, 3-, and 5-year survival rates across all tumor stages.

Discussion: Even with national screening initiatives and advances in therapeutics, improvements in lung cancer survival have not been equitably distributed across regions. Contextual deprivation continues to exert a strong influence on survival disparities, reflecting enduring structural barriers within deprived communities.

Conclusion: Addressing socioeconomic deprivation and ensuring equitable access to high-quality cancer care are essential to reducing regional survival inequalities. Policies that incorporate social equity into cancer control strategies are needed so that future advancements translate into improved outcomes for all patients.

Context: Despite the growing evidence suggesting an association between screen time exposure (STE) in children and autism symptoms, an understanding of this among the general child population is lacking.

Objectives: We aimed to determine the associations between STE and results on the Modified Checklist for Autism in Toddlers, Revised with Follow-Up (M-CHAT-R/F) questionnaire, in children from a multi-ethnic population-based sample in XXX.

Methods: This cross-sectional study included children between 17 and 24 months of age, with no known developmental conditions, attending routine visits in primary care. Caregivers reported daily screen time via a questionnaire and completed the M-CHAT-R/F (standard administration protocol followed). Logistic and linear regression analyses and structured equation modelling including covariates were conducted.

Results: The sample comprised 5,336 multi-ethnic children (mean age 18.6 ± 0.9 months, 64.2% Chinese ethnicity, 23.9% Malay, 5.8% Indian). Mean STE was 1.31 ± 1.33 h/day. Increased STE was associated with a higher likelihood of a positive M-CHAT-R/F screen (OR = 1.24, 95% CI [1.01, 1.53], $p < 0.05$). Higher STE was associated with greater odds of having a response of concern for the social-communication questions but not those on motor/sensory aversion. Both the final M-CHAT-R/F score and the screening outcome was directly explained by STE in the structural equation model ($\beta = 0.05$, 95% CI [0.03, 0.07], $p < 0.001$ and OR = 1.24, 95% CI [1.01, 1.53], $p < 0.05$).

Discussion: Strengths of study include the large, community-based multi-ethnic study sample. Limitations include: cross sectional nature limits ability to infer causality, potential reporting bias of STE. In future studies, factors such as screen time content and co-viewing could be explored.

Conclusion: Findings suggest a significant association between higher STE and autism symptoms, especially social communication domain. Evaluation and support of children with a positive M-CHAT-R/F screening result should include addressing STE and mitigating exposure.

Seonmee KIM, Dohee LEE

Korea University Guro Hospital, Seoul, Corée (République de)

Context: Osteoporosis and obesity are highly prevalent chronic conditions that pose major health challenges worldwide. While both are traditionally viewed through distinct clinical lenses, their coexistence is increasingly recognized as an important issue in primary care, where early screening and comprehensive risk management are critical. Understanding how these conditions interact to influence long-term mortality may help improve preventive strategies in aging populations

Objectives: To examine the combined effects of osteoporosis and obesity on all-cause and cardiovascular mortality in a nationally representative Korean population, emphasizing implications for integrated primary care management.

Methods: Data were drawn from the Korea National Health and Nutrition Examination Survey (2007–2012) linked with national mortality records through 2019. Adults aged ≥50 years who underwent dual-energy X-ray absorptiometry (DEXA) were included (n≈21,300). Osteoporosis was defined as a T-score ≤ −2.5, and obesity was defined by DEXA-measured body fat percentage. Participants were categorized into four groups according to osteoporosis and obesity status (G+O+, G+O−, G−O+, G−O−). Cox proportional hazards models were applied to estimate hazard ratios for all-cause and cardiovascular mortality after adjustment for demographic, behavioral, and clinical factors.

Results: Over a median follow-up of 8.2 years, approximately 2,100 deaths occurred, including 600 cardiovascular deaths. Preliminary analyses suggest that osteoporosis independently increases mortality risk and may amplify adverse outcomes when combined with obesity. Full analyses will be presented at the conference.

Discussion: These findings underscore the need for a holistic approach to managing patients with osteoporosis and obesity in primary care. Lifestyle counseling, fall prevention, and cardiovascular risk control should be integrated to address overlapping metabolic and skeletal risks.

Conclusion: The coexistence of osteoporosis and obesity may be a key determinant of long-term survival among older adults. Proactive screening and multidisciplinary management strategies in primary care can improve outcomes for this growing patient population.

Corresponding author: Seonmee Kim, ksmpdh@korea.ac.kr

ID 987- Therapeutic management of climacteric symptoms: a survey of general practitioners in XXX (2024)

Matheus MATOS, Fabio QUAGLIATO, Soraya VARELLA, Clarice ITO, Maria Eduarda SOUZA, Marcelo DUTRA

Centro Universitário Barão De Mauá, Ribeirão Preto, Brésil

Context: Population aging demands strategies that promote physical, mental, and social well-being, particularly within Primary Health Care. In a Family Health Unit in XXX, a group of older adults presented signs of social isolation, low mood, and mild functional limitations. In response, a structured handicraft group was implemented as a strategy to stimulate cognition, strengthen social bonds, and enhance overall quality of life.

Methods: The project was carried out over three years and involved approximately 17 older adults aged 57 to 89. Weekly sessions were conducted by the Unit Health team and included activities such as dish-towel painting, knitting, crocheting, emphasizing fine motor coordination, attention, memory, and creative expression. The Family and Community Medicine team monitored participants' physical and emotional conditions, adapting activities to individual needs. Strengths of the project included continuity, multidisciplinary involvement, and a welcoming environment. Limitations included material constraints and reliance on professional engagement to sustain the group.

Originality: Although social groups are common in Primary Care, the structured use of handicraft activities as a therapeutic tool, combined with the longitudinal follow-up provided by the Family and Community Medicine team, proved to be an innovative approach within the Unit Health. While the literature highlights the benefits of artistic interventions for older adults, few reports describe long-term initiatives integrated with clinical care, which distinguishes this experience.

Lessons learned and future implications: The experience demonstrated that cultural and artistic activities help build social ties, promote a sense of belonging, and may reduce symptoms of depression and anxiety. Future steps include expanding community partnerships, diversifying artistic techniques and developing quantitative assessment tools.

Discussion: The implementation of a structured handicraft group within the Family Health Unit demonstrated that artistic and manual activities can serve as powerful catalysts for physical, emotional, and social well-being among older adults. The observed outcomes align with evidence that group-based creative interventions promote cognitive stimulation, reduce loneliness and support functional capacity in aging populations.

Conclusion: Integrating manual activities, creativity and biopsychosocial care reinforces the central role of Primary Health Care in promoting health.This handicraft group positively impacted older adults' well-being and represents a replicable model for other communities, contributing to comprehensive and holistic care for older populations.

Matheus MATOS, Fabio QUAGLIATO, Soraya VARELLA, Matheus FALEIROS, Camila MARTINELLI, Carolina MENEGHETTI, Marcelo DUTRA, Lucila ANGELOTTI

Centro Universitário Barão De Mauá, Ribeirão Preto, Brésil

Context: Meningitis is a severe infection of the meninges, primarily caused by viruses and bacteria, characterized by high lethality and rapid dissemination. Therefore, it is a notifiable disease in XXX. In 2023, the country recorded 14,281 confirmed cases and 1,604 deaths.

Objectives: This study aimed to analyze the epidemiological data on the incidence and temporal trends of meningitis in XXX between 2019 and 2023.

Methods: This ecological study used secondary data from the Notifiable Diseases Information System (SINAN). Incidence rates (per 100,000 inhabitants) were collected and organized into a time series, with emphasis on variations during and after the COVID-19 pandemic.

Results: The COVID-19 pandemic affected the dynamics of infectious diseases. Facciola et al. (2023) observed a 41% decrease in notifications during the pandemic period, including meningitis and tuberculosis. In the post-pandemic scenario, Bloom et al. (2023) reported a global increase in invasive meningococcal disease, attributed to declining vaccination coverage.

Discussion: In XXX, meningitis rates dropped in 2020–2021: a 57.6% decrease nationwide, 61.5% in XXX, and 32.6% in XXX. However, in 2023, the municipal rate reached 29.93 cases per 100,000 inhabitants, a 148.7% increase compared to 2022. Kadambari et al. (2019) also highlighted the rise in viral meningitis after isolation, associated with the resumption of social interactions and reduced vaccination coverage.

Conclusion: The decline in notifications during the pandemic reflects the effect of distancing measures, while the subsequent increase highlights the importance of continuous epidemiological surveillance, early diagnosis, and strengthened vaccination campaigns. Monitoring meningitis trends is essential for understanding the impact of health policies and preventing outbreaks in urban centers such as XXX.

ID 1550- Therapeutic Patient Education (TPE): From Learners' Feedback to Practical Multidisciplinary Collaboration Experiences

Fakhrunnisa AKBAR

The Indus Hospital Karachi, Karachi, Pakistan

Context: Cobalamin deficiency, B12 deficiency, macrocytic anemia, megaloblastic anemia, nutritional anemia, vitamin B12 deficiency, Pakistan

Objectives: To examine the associations of sociodemographic factors, comorbidities, diet, medications, vitamin D levels, hematological indices, and symptoms with vitamin B12 status among primary care patients in Karachi, Pakistan

Methods: This cross-sectional study was conducted in 2023 at the tertiary care hospital. Adults recently tested for vitamin B12 as advised by physicians were enrolled (n=252). Data on demographics, comorbidity, medications, diet, and symptoms were collected through structured interviews, alongside BMI and laboratory results. Associations were analyzed using descriptive statistics, Chi-square, and correlation coefficient, with $p<0.05$ considered significant.

Results: Of 252 participants (71.4% female, median age 46 years), fatigue (79.5%), muscle weakness (73.2%), and numbness/tingling (69%) were the most frequent symptoms in those with B12 deficiency or insufficiency. Decreased appetite (p=0.003) and weight loss (p=0.010) were significantly associated with low B12 levels. Dietary patterns showed strong

associations: reduced milk intake (72% deficient) and infrequent red meat consumption (49.6% deficient) were linked to deficiency. Vitamin D correlated positively with B12 levels (r=0.215, p=0.006), while mean corpuscular volume correlated negatively (r=-0.151, p=0.019). No significant associations were found with BMI (p=0.175), comorbidities (p>0.05), or metformin/PPI use (p>0.05).

Discussion: This study demonstrate that low vitamin B12 levels are strongly associated with inadequate consumption of milk and red meat, highlighting the central role of dietary insufficiency rather than chronic comorbidities or medication use. Constitutional symptoms—including decreased appetite and weight loss—alongside neurological manifestations such as numbness and weakness, were more prominent among deficient individuals, reinforcing their value as clinical indicators. The positive correlation between vitamin D and B12 levels suggests shared nutritional and socioeconomic determinants affecting overall micronutrient status. The absence of significant associations with BMI, metformin, and PPI use indicates that diet and socioeconomic factors may be more influential in this setting.

Conclusion: Low vitamin B12 levels were associated with specific dietary insufficiencies, constitutional and neurological symptoms, and hematological indices. These findings highlight the need for heightened clinical awareness and integration of dietary counseling within primary care. These findings highlight the need for targeted screening and interventions to prevent deficiency in underprivileged populations

ID 691- Three magic ingredients in a seedbox for General Practitioners: a sparkling recipe for cultivating Planetary Health in primary care teams

Didier THERY [(1)], Paul TRANIER [(2)]

(1) Aix Marseille Universite, Marseille, France
(2) Universite Paris Cite, Paris, France

Context: CURRENT KNOWLEDGE ON THE MANAGEMENT OF ANKLE SPRAINS IN PRIMARY CARE: A SYSTEMATIC REVIEW OF THE LITERATURE

Objectives: Objective : Acute ankle sprains are one of the most common reasons for consulting a general practitioner. The aim of this study was to analyze recent data from the literature on the management of ankle sprains and compare it with previous French recommendations and the new HAS 2025 recommendations.

Methods: Materials and methods : This systematic review of the literature was conducted using the PubMed, Cochrane, Lissa, and Google Scholar databases, including randomized trials, meta-analyses, systematic reviews, and recommendations published between 2005 and 2024. The data were synthesized according to the main areas of management: diagnosis, initial treatment, immobilization, paraclinical examinations, drug treatments, rehabilitation, return to sport, alternative therapies, and surgery.

Results: Results : OARs are confirmed as the diagnostic tool of choice. The RICE protocol, although widely used, is based on a low level of evidence and provides only temporary symptomatic relief. Functional supports are superior to strict immobilization, except in rare cases of severe sprains. Paracetamol and topical NSAIDs are the first-line analgesics; oral NSAIDs should be reserved for selected cases, and opioids are not indicated. X-rays remain the first-line paraclinical examination, while ultrasound appears promising but requires further studies to clarify its role. Active, early, and proprioceptive rehabilitation is key to preventing recurrence, while passive modalities have not been shown to be effective. Return to sport must be individualized, guided by clinical, functional, and psychological criteria. Surgery does not provide lasting functional benefit and should remain exceptional.

Discussion: Discussion : The 2000/2004 recommendations were already ahead of their time, favoring functional treatment, paracetamol, and proprioceptive

rehabilitation. Recent data confirm these choices and refine them, particularly through the use of topical NSAIDs, the relativization of the RICE protocol, and the use of validated scores (FAAM, Ankle-GO, ALR-RSI).

Conclusion: Conclusion : Optimal management of ankle sprains is based on a functional approach that is well thought out and tailored to the clinical context. The 2025 recommendations confirm the relevance of historical guidelines, while incorporating recent evidence to guide follow-up and ensure a safe return to sport.

Swaleha TARIQ, Samar ZAKI, Hamida FARAZDAQ, Tabinda ASHFAQ, Sadia MASOOD

Akuh, Karachi, Pakistan

Context: Family physicians must be competent to manage the urgent care problems presenting to them for appropriate patient care. This workshop gives learners the knowledge and hands-on experience to manage common urgent cases confidently and recognize when emergency referral is needed. Through case based simulation and real-world scenarios, participants strengthen their skills, build confidence, and learn to provide safe, effective, and compassionate care for every patient in a safe enviorment. Moreover, Artifcial intelligence based scenario will be used to integrate innovative technology in teaching and learning

Objectives: Recognize and assess key urgent care presentations. Formulate appropriate initial management plans according to the recent guidelines. Identify red flags that warrant referral to emergency department Demonstrate effective communication and teamwork in acute scenarios. Using innovative technology (Artificial Intelligence) based scenarios to promote effective teaching and learning to promote learning in a safe enviorment. Reflect and apply feedback to improve performance.

Teaching method and workshop: Teaching method: Case based simulations Participants: Divided into 4 small groups for active participation. Each small group will be facilitated by a facilitator. Each group will discuss two case based simulation scenarios so tatal 8 scenarios will be di

Expected outcomes: By the end of the session the participants will be able to manage the common problems presenting in the Family medicine urgent care setting including appropriate referral.

Conclusion: This urgent care workshop is designed to empower learners with the skills and confidence needed to provide timely, effective patient care. By combining practical knowledge with hands-on experience, participants learn not only how to manage common urgent cases but also how to recognize situations that require immediate emergency referral. The workshop fosters critical thinking, sharpens decision-making, and emphasizes patient safety in a simulation based enviorment helping learners grow professionally. The integration of innovative Artificial Intelligence based scenarios will promote effective teaching and learning in a safe enviorment. The feedback to the trainees will help in invidualized learning and hence improving the quality of patient care.

ID 1746- Thyreotoxicosis masked as essential tremor in a young woman

Hui ZHAO, Xin FENGLING

The Department Of Health Management, Center Hospital Of Dalian University Of Technology, Dalian, Chine

Context: Multimorbidity (more than 2 chronic diseases or health conditions) was common in the Chinese population. Patients with multimorbidity have more complex healthcare requirements, which often result in more frequent hospitalizations, premature death, longer hospital stays, and greater costs.

Objectives: Little research has examined the relationship between multimorbidity phenotypes and clinical outcomes. Hence, this

study aimed to investigate the clusters of multimorbidity and ascertain the relationship between the clusters and hospital service utilization and mortality.

Methods: This population-based retrospective cohort study used data from 13,792 China Health and Retirement Longitudinal Study (CHARLS) participants.This population-based retrospective cohort study used data from the CHARLS, the baseline data collected in 2011. Participants were followed up in 2013, 2015, and 2018. The questionnaire information, laboratory data, hospital admission, and medication records were captured at each time. Data were analyzed between September 2023 to May 2024. Cox proportional hazards models were used to evaluate associations between multimorbidity clusters and future mortality. Negative binomial regression models were used to evaluate the relationship between the health service burden associated with various multimorbidity groups.

Results: Out of the 13,792 participants who were recognized as having multiple health conditions, four clusters were identified as multimorbidity clusters, including digestion and respiratory, hypertension, heart and digestion, and cancer. During the follow-up of 7 years, 1,743 individuals died. In a multifactorial Cox model, participating in the hypertension cluster was found to be associated with a higher risk of all-cause mortality [hazard ratio (HR): 1.398] compared to the cancer cluster. In 2018, the heart and digestive cluster had the highest risk of hospitalization. The incidence rate ratio (IRR) for hospital stays in the heart and digestion cluster was 1.661, indicating an elevated risk.

Discussion: These data indicate that multimorbidity manifests in various ways, and the clusters of multimorbidity are linked to varied levels of mortality and health burden in the general population. These findings could aid in identifying the population, rather than individual patients, to target treatments that can support healthcare systems.

Conclusion: These specific multimorbidity patterns emphasize the need to accurately and specifically identify, prevent, and manage multimorbidity in Chinese.

ID 161- Thyroid diseases in men

Jure BOSANAC

Zdravstveni Dom Črnomelj, Črnomelj, Slovénie

Context: Tick-borne encephalitis (TBE), which is highly endemic to XXXXXXXX, often follows a biphasic course. First phase encompasses fever, malaise, fatigue, myalgias, headache, arthralgias, leukopenia, thrombocytopenia and abnormal liver tests, followed by improvement. About 10% of patients then develop meningitis, meningoencephalitis or meningoencephalomyelitis.

Methods: A 64-year-old woman, later diagnosed with TBE, presented to primary practice in XXXXXXXX in May 2025 with 10-day history of cough, sneezing, myalgia, nasal and ocular discharge, joint pain and evening sweats. Physical examination, vital parameters and CRP were normal with borderline thrombocytopenia and low lymphocytes. Seven days later she had a fever, headache, high neutrophils and normal CRP. Next day somnolence, frontotemporal headache, neck pain, vertigo, poor concentration, photophobia and high fever developed. Rapid neurological exam was normal.

Originality: Most literature focuses on TBE cases where CNS infection has already developed and is written from the perspective of tertiary care. One study showed inadequate knowledge of TBE and its symptomatology in primary care doctors. Another concluded that clinical manifestation is often unclear in the initial phase of TBE and in cases manifesting without CNS involvement. There is a lack of similar publications about TBE in primary care.

Lessons learned and future implications: TBE is an important yet challenging diagnosis to make in primary care. Efforts at local and national levels focused on providing an up-to-date structured education about TBE epidemiology, clinical features and laboratory findings to family physicians in high-incidence

areas, could increase the number of diagnoses in early stages.

Discussion: Diagnosis of TBE is rarely made in the first phase due to nonspecific presentation. Even in highly endemic areas, many causes of similar disease manifestations must be considered. Fever, malaise, fatigue, myalgia, headache, arthralgia, leukopenia, thrombocytopenia and abnormal liver tests, however, are common and could contribute to improved early recognition of TBE. This case illustrates such nonspecific TBE presentation, where correct diagnosis was established only after CNS involvement.

Conclusion: This case report highlights the nonspecific presentation of TBE in the first phase and calls for a structured education about TBE for all family physicians working in high-incidence areas in order to improve early recognition and diagnosis of TBE and thus enhance patient care.

ID 2299- Thyroid ultrasound screening and thyroid function in asymptomatic adults in primary care

Kui Ting TEONG

General Medicine, Khoo Teck Puat Hospital, Singapore, Singapore, Singapour

Context: Artesunate is the standard treatment for severe malaria. Although clinical recovery is typically rapid, a delayed haemolytic reaction can appear 1–3 weeks later, often when the patient has transitioned back to primary care. Awareness in community settings is therefore crucial, especially in regions where malaria is uncommon.

Methods: A 39-year-old man was treated with artesunate for severe Plasmodium falciparum malaria. He improved quickly and was discharged with stable haemoglobin. Two weeks later, he presented with fatigue, dark urine and jaundice. Tests showed severe anaemia, raised LDH, indirect hyperbilirubinaemia and low haptoglobin. The direct antiglobulin test (DAT) was weakly positive, creating uncertainty regarding autoimmune haemolysis. Further evaluation excluded G6PD deficiency, drug-induced causes, recurrent malaria and mechanical haemolysis. He was admitted and received transfusion. At six-week review, he was asymptomatic and the DAT had reverted to negative, indicating the initial weak result was likely a transient, infection-related false positive, while the overall pattern was consistent with post-artesunate delayed haemolysis (PADH).

Originality: PADH is uncommon and often under-recognised in non-endemic settings. This case is notable for the initially weakly positive DAT, which later reverted to negative, adding diagnostic complexity and demonstrating the importance of interpreting results within clinical context. The delayed haemolysis pattern also reflects the mechanism of splenic "pitting", where once-infected erythrocytes are cleared from circulation, leading to reduced red cell survival

Lessons learned and future implications: Patients treated with artesunate should be advised about delayed haemolysis, and follow-up blood tests at 1–3 weeks can facilitate early detection. Understanding transient DAT positivity reduces the risk of incorrect autoimmune labelling.

Discussion: PADH typically presents 1–3 weeks after artesunate therapy with raised LDH, indirect hyperbilirubinaemia and low haptoglobin. The process involves splenic pitting of previously parasitised erythrocytes, explaining the predictable timing. Although DAT is usually negative, transient weak positivity may occur during infection and should be interpreted cautiously. Early recognition and shared follow-up between hospital and primary care are important as delayed haemolysis often emerges after discharge.

Conclusion: Post-artesunate delayed haemolysis is an important clinical entity. Increased awareness and structured post-treatment monitoring can support earlier diagnosis and reduce complications, particularly in regions where severe malaria is infrequently encountered.

ID 207- Tick-borne encephalitis - a diagnostic challenge in primary care?

Clément PORCHER

Département De Médecine Générale, Université De Poitiers, Chauray, France

Context: Sexuality is a topic that is increasingly present in public debate and in culture. It is also an important aspect of overall health. Yet it remains a taboo subject for both general practitioners and patients. We therefore looked into the practices, expectations, and barriers that General Practitioners face when addressing this topic during consultations.

Objectives: To analyze the perceptions of GPs regarding the discussion of sexuality in consultations with their patients, in order to identify barriers and facilitators.

Methods: A qualitative study based on 13 semi-structured individual interviews conducted with a representative sample of practicing GPs. The data were analyzed using an interpretative phenomenological method.

Results: All interviewed GPs unanimously acknowledged that addressing sexuality falls within their professional scope. However, the topic remains infrequently discussed and is approached unequally between genders. For male patients, aside from the pubertal period when screening for sexually transmitted infections is addressed, sexuality is almost never discussed. Among female patients, it is discussed when contraception is the reason for consultation and during screenings or smear tests, if performed by the practitioner. The most overlooked patients in discussions about sexuality are the elderly. The most frequently reported barrier is discomfort in addressing the topic, which is described as a societal taboo. Lack of routine inquiry is also mentioned, as sexual health questions are not commonly included in standard consultations. Gender differences between the practitioner and the patient present a significant challenge. The main facilitators seem to be the presence of informational materials in waiting rooms and the establishment of dedicated consultations.

Discussion: This study highlights a paradox between the prominent place that sexuality holds in the public sphere and the persistent difficulties in addressing it during General Practice consultations.

Conclusion: Although GPs are convinced of the necessity of discussing sexuality with their patients, they struggle to do so regularly and inclusively. Discomfort related to gender, age, and societal taboos hinders these discussions. Displaying information in waiting rooms and implementing dedicated consultations appear to help overcome these difficulties.

ID 42- Ti'Doc Medical Congress

Munya KOENIG

Doctor, Amiens, France

Context: In XXX, there is more difficulties to have access quickly to primary care, moreover we observed that parents present a lack of knowledges, while newborn's medical care depends of parental vigilance. Improving parental knowledge on newborn's health by general practitioners could lead to a reduction of tension in primary care. Do multiparous have better knowledge as primiparous ?

Objectives: Compare medical knowledge of primiparous versus multiparous parents with respect to the main pathologies in newborns aged 0-12 months. Secondly, develop a brochure with basic information on newborns health.

Methods: We obtained CNIL authorization. We included parents with at least one child under twelve months, french speaking-reading-friendly. It was a single-center retrospective observational quantitative study. A questionnaire addressing the first year period was distributed in maternity and pediatrics emergency. Statistics data were compared with a Chi2-Test, Student-test, Fischer-Test, Wilcoxon-test. Moreover, an univarious and a multivarious analysis were made.

Results: 134 responses were obtained: 63 composed the group primiparous and 71 the group multiparous. 100% of the respondents

had under the middle mark, we found a significant difference regarding the number of false responses between multiparous and primiparous (29,6% vs 57,1% p=0,001). Infact, only 53% (p= 0,241) correctly defined fever, 30% didn't define correctly diarrhea (p= 0,229). Infront of fever, we also observed a tendency towards self-medication in the multiparous group. Our results confirmed our initial hypothesis, that multiparous skills gained through medical advice, provides them better knowledges as primiparous.

Discussion: Our sample was comparable to national statistics: the average age was 29,7 years (5.3) p<0,001; 82,9% were women p= 0.783; 53% were multiparous p<0,001; 51,2% were high-level study background p= 0.069. The study was limited by multiple bias linked to our selection mode (paper questionnaire) as selection, input, information, temporal biases. However our results were relevant, in agreement with literature's data.

Conclusion: We ascertained a global lack of parental knowledge regarding basic definitions, simple cares, emergency signs. Parents expressed their need to be informed. It seems important to develop standards preventing actions to help parents with newborn's health: as brochures, dedicated consultations, online articles/videos. It may improve parental empowerment in primary care.

ID 2017- Time motion and patient satisfaction in outpatient department at a government tertiary hospital

Benarbia LEILA

Université Paris Cité, Paris, France

Context: Access to abortion is a major public health issue. The literature reports differences in the time taken to seek an abortion. This can be explained by inequalities in healthcare provision, but also by inequalities in access to care linked to social determinants of health, like migration. The choice of method, and even the possibility of an abortion, are also conditioned by pregnancy dating.

Objectives: The aim of this study was to assess the impact of migration on the delay in access to medical abortion, and to analyze the link between migratory background and access to care.

Methods: This was a retrospective, descriptive and analytical observational study via an online questionnaire. We surveyed adults who had requested an abortion in the last five years. The primary endpoint was the time between discovery of pregnancy and consultation for medical abortion. Secondary criteria were the date of pregnancy at the first abortion consultation and the time between the two consultations.

Results: 153 participants had undergone an abortion, 77% a medical abortion. The sample's health literacy concerning abortion was low. A comparison of participants by migratory group (first-generation migrants, second-generation migrants and non-migrants) revealed significant differences. Migrant participants were more likely to consult at the hospital and at a later date. They also had more difficulty booking appointments and more delays in complementary examinations.

Discussion: The sample had a high socio-economic status and good access to care in general. Participants who had a primary care physician (PCP) were more aware of the time required to carry out an abortion, had more reliable sources of information, reported fewer abortion-related delays due to complementary examinations, had fewer difficulties making an appointment. Having a PCP was found to be an indicator of good access to care, as it is correlated with socio-economic level and health literacy.

Conclusion: Common barriers to the entire population were identified: availability of care and health literacy concerning abortion. We also found barriers specific to the migrant population: socio- economic and health literacy in general. We observed that second-generation migrant participants had a better socio-economic level than first-generation migrants, but retained informational barriers compared with non-migrants.

Ema DEJHALLA [(1)] , Tina ZAVIDIĆ [(2)], Branislava POPOVIĆ [(2)], Tatjana ČULINA [(2)]

(1) Medical Centre For Occupational Health Rijeka-Family Medicine Office, Rijeka, Croatie
(2) Faculty Of Medicine, University Of Rijeka, Rijeka, Croatie

Context: Metabolic syndrome (MetS) is increasingly prevalent among young adults, largely influenced by diet quality and physical activity. University students represent a vulnerable group due to irregular routines, academic stress, and varying health behaviors.

Objectives: This study aimed to determine the prevalence of MetS among students at the University of Rijeka and examine its associations with dietary habits, physical activity, gender, and faculty type (health vs. non-health).

Methods: A cross-sectional study was conducted from September 2024 to March 2025 among 217 randomly selected students aged 18–24 years from 16 faculties. Data collection included the Mediterranean Diet Adherence Screener (MEDAS), the International Physical Activity Questionnaire Short Form (IPAQ-SF), and a general sociodemographic questionnaire. Anthropometric measurements (height, weight, waist circumference) and biochemical markers (fasting glucose, triglycerides, HDL cholesterol) were obtained following standardized procedures. MetS was diagnosed using IDF criteria supplemented by the Polish Experts Consensus (2022). Statistical analyses included descriptive tests, t-tests, ANOVA, Spearman's correlations, and multivariate logistic regression.

Results: MetS prevalence was 5.5%. Significant factors associated with metabolic risk included obesity (BMI, $p < 0.05$), low physical activity ($p < 0.05$), elevated blood pressure ($p < 0.01$), high triglycerides ($p < 0.05$), and increased waist-to-height ratio ($p < 0.01$). Female students reported lower physical activity ($p < 0.05$), while non-health faculty students showed lower Mediterranean diet adherence and lower physical activity (both $p < 0.05$). Higher MEDAS scores correlated with lower BMI and lower triglycerides ($p < 0.05$). Logistic regression indicated that waist circumference and triglycerides were significant predictors of WHR, while BMI showed a negative association. For WHtR, triglycerides, systolic blood pressure, and BMI were significant positive predictors. Glucose, HDL cholesterol, and diastolic blood pressure were not significant in either model.

Discussion: Lifestyle patterns—particularly diet and physical activity—demonstrate strong associations with metabolic risk. Differences by gender and faculty type highlight groups that may benefit from targeted health promotion.

Conclusion: The 5.5% MetS prevalence underscores the need to promote Mediterranean diet adherence and physical activity among university students, with particular focus on females and non-health faculty students. Longitudinal studies are recommended to evaluate intervention effectiveness.

ID 1910- Tinea corporis incognito following systemic corticosteroid self-medication: a zoonotic infection masked as psoriasis

Xénia WÖSTMANN

Society Of General Practitioners Of Slovakia, Somotor, Slovaquie

Context: 41-year-old woman with no significant medical history came in for an examination due to pain in her right shoulder. The pain appeared suddenly on Friday evening after she had hung up laundry. Due to the severe pain, she was examined at the emergency room on Friday evening, Saturday, and Sunday, with the conclusion being a traumatic strain of the right shoulder. Analgesics were administered with temporary relief. Status presens: patient exhausted and sweaty, she stated that she had been coughing for the last few days, she had a

temperature of up to 38.5°C once, right shoulder is sensitive, mobility normal. Auscultation of the right lung weakened from the base to the scapula. A POCT CRP test elevated (above 200 mg/ml) a POCUS / Point of care Ultrasound/, showed no sliding and extensive effusion of the right lung. Diagnosis: V.s. lung empyema. The patient was transported to the pulmonary department in emergency mode. Excesive empyema of the right lung was confirmed. Although the course was complicated, patient survived and is doing relatively well.

Methods: The correct diagnosis was made in a very short time, approximately 15 minutes, based on a detailed medical history, thorough clinical examination, and the use of POCT methods - POCT CRP and POCUS.

Originality: This case study is unique in that, despite the patient being seen several times in the emergency room, her complaints were downplayed and she was misdiagnosed. I have known the patient for more than 20 years, so I knew at first glance that her condition was serious.The use of POCUS imaging helped me convince the patient, who believed she "only" had a pulled shoulder, to undergo acute hospitalization.

Lessons learned and future implications: POCT devices are not only helpful in determining an early diagnosis, but also helps save lives.

Discussion: How are POCT devices/methods used in your country?

Conclusion: Since 2024, general practitioners in XXXX are able to use a new method within POCT devices, the point-of-care ultrasonography (POCUS). It can be used independently or in combination with other POCTs. POCT- CRP, Troponin T, Nt-pro BNP, and D-dimer testing.Combining POCT methods in practice helps both doctors and patients.

ID 1142- Agenoethics: Re-grounding Responsibility in Agency Beyond Biological Life

Enmanuel CHIRINO, Pilar SANZ, Eva DE LA TORRE BUEDO, Sona GARCIA

000, Madrid, Espagne

Context: Optic neuritis in individuals living with HIV is an uncommon and diagnostically challenging condition. Unlike typical optic neuritis associated with multiple sclerosis, HIV-positive patients require a broader differential diagnosis that includes infectious, inflammatory, and demyelinating processes. This case highlights the crucial role of primary care in the early detection of neuro-ophthalmic emergencies and the importance of coordinated, multidisciplinary evaluation

Methods: A 52-year-old woman with long-standing HIV infection presented to her primary care physician with a one-week history of right-eye pain, visual discomfort, and progressive visual-field loss. Physical examination revealed a non-reactive right pupil and confirmed visual-field impairment. She was urgently referred to ophthalmology. Investigations included OCT, brain MRI, and pending CSF and serological studies (oligoclonal bands, anti-AQP4, and anti-MOG antibodies). High-dose corticosteroids were administered during hospitalization. Clinical evolution and specialist assessments were documented through discharge

Originality: This case is clinically relevant due to the diagnostic complexity created by HIV infection. MRI showed multiple subcortical lesions, but only one with clear demyelinating features—an ambiguous pattern that sits at the crossroads of several entities: early MS, NMOSD, MOGAD, or HIV-related white-matter changes. The case adds value to the limited literature addressing optic neuritis in HIV-positive individuals and emphasizes the importance of integrating clinical intuition with advanced diagnostics

Lessons learned and future implications: Primary care intuition and familiarity with the patient's history are essential for detecting early neuro-ophthalmic warning signs. HIV infection broadens the differential diagnosis of

optic neuritis and requires multidisciplinary evaluation. Timely referral and rapid corticosteroid treatment significantly improve outcomes.

Discussion: The patient exhibited significant clinical improvement following corticosteroid therapy, with visual acuity rising from 0.4 to 0.8 and resolution of retro-ocular pain. This favorable outcome was made possible by the prompt recognition in primary care that the presentation was not benign. The early suspicion of optic nerve pathology triggered rapid referral, timely imaging, and initiation of therapy—crucial factors in preserving optic nerve function.

Conclusion: Early identification and coordinated care between primary and specialist services were decisive in ensuring rapid diagnosis and optimal visual recovery. Further evaluation will clarify the underlying demyelinating process and guide long-term management in the context of HIV.

Genelyza Theresa GARCIA

City Healh Office-Dagupan City, Dagupan City, Philippines

Context: Lung cancer is the leading cause of cancer-related mortality among non-AIDS-defining malignancies in people living with HIV (PLWH). Despite advancements in antiretroviral therapy, PLWH continue to face elevated risks for lung cancer due to various factors.

Objectives: To assess the prevalence and contributing risk factors of lung cancer among PLWH.

Methods: A comprehensive literature review was conducted, identifying 1,787 records through a systematic search strategy. After removing duplicates and screening titles and abstracts, 180 full-text articles were evaluated for eligibility. Thirteen studies met the inclusion criteria, encompassing data from eight countries with a total sample size of 1,275,734 individuals. The quality of each study was assessed using the Newcastle-Ottawa Scale for cohort studies.

Results: The standardized incidence ratios (SIRs) for lung cancer among PLWH ranged from 0.70 to 4.8 across the included studies. Notably, studies from China reported higher SIRs of 4.8 (95% CI: 4.4–5.1) for males and 4.2 (95% CI: 3.5–5.0) for females. Key risk factors identified include higher smoking prevalence among PLWH, immunosuppression, and low CD4 counts. While some studies suggest a potential link between highly active antiretroviral therapy (HAART) and lung cancer development, the evidence remains inconclusive.

Discussion: Lung cancer incidence is two to three times higher in people living with HIV, driven by factors such as aging, smoking, and HIV-related immunosuppression, despite improvements in survival associated with HAART. Most cases are non-small-cell lung cancers, particularly adenocarcinoma, reflecting patterns in the general population, though the underlying mechanisms in the context of HIV remain unclear.

Conclusion: Lung cancer remains a significant health concern for PLWH, with risk factors such as smoking, immunosuppression, and low CD4 counts playing pivotal roles. To mitigate this risk, it is crucial to implement smoking cessation programs, initiate early antiretroviral therapy, and maintain a high index of suspicion when evaluating respiratory symptoms.

(1) The Public Health Center Of The Ministry Of Health Of Ukraine, Kyiv, Ukraine
(2) World Health Organization, Country Office In Ukraine, Kyiv, Ukraine

Context: Tobacco use is a leading risk factor for non-communicable diseases (NCDs), and primary care physicians play a key role in smoking cessation. The WHO First Clinical Guidelines on Tobacco Cessation for Adults highlight that brief advice delivered by healthcare providers is among the most effective interventions to support smoking cessation.

Objectives: We examined the current practices, barriers, and opportunities faced by the regional primary care physicians in providing smoking cessation counseling.

Methods: In 2022, 45 in-depth telephone interviews were conducted with primary care physicians across three regions of XXX to explore various aspects of smoking cessation counseling.

Results: A total of 96% of doctors recognize smoking as a significant risk factor for the development of NCDs. The same portion reported providing smoking cessation counseling, with the frequency of consultations influenced by patient-specific diseases (cardiovascular disease, diabetes, chronic obstructive pulmonary disease, hypertension), symptoms (shortness of breath, cough, high blood pressure, pregnancy), age and smoking history. All physicians can identify smokers through observable indicators, such as smell, hoarse voice, cough, and yellowing of fingers. Most physicians (89%) highlighted smoking as an NCD risk and used tailored question–answer counseling with examples and statistics. Many physicians highlighted the limited evidence on the health effects of newer tobacco and nicotine products. 71% of doctors consistently documented patient's smoking in medical records and 70% of doctors used this information in clinical decisions, including treatment adjustments, medication choices, and monitoring smoking behavior. Half of physicians reported that patients rarely sought smoking cessation counseling on their own. Self-referral typically occurred when patients' health declined or they recognized smoking's impact on disease progression.

Discussion: Since heavy smokers are primary recognized by doctors, they are more likely to receive counseling than light smokers, indicating inequalities in access to care. Limited evidence on the risks of newer tobacco and nicotine products restricts physicians' ability to provide persuasive smoking cessation counseling.

Conclusion: Our study highlights the need for regular training of healthcare professionals in effective, evidence-based interventions to raise awareness of smoking's impact and strengthen tobacco control. Findings may inform strategies for smoking cessation and prevention of smoking-related diseases globally.

ID 1034- Transforming a family physician-led home visit program to teach social determinants of health in undergraduate education: a longitudinal curricular and experiential program

Seung Kwon HONG

School Of Public Health, Seoul National University, Seuol, Corée (République de)

Context: Korea's healthcare system has expanded alongside rapid economic growth yet continues to exhibit structural imbalances, including metropolitan concentration of resources, weak capacity in essential disciplines, and uneven access to timely emergency and maternal–child services. Demographic aging, chronic disease burdens, and widening regional disparities intensify these pressures and challenge the sustainability of both primary and hospital care.

Objectives: To assess national policy responses introduced since 2020 to stabilize essential services and improve regional equity, and to appraise early signals of implementation and system effects.

Methods: We conducted a documentary review of government plans, legislation, and budget announcements from 2020–2025, complemented by secondary statistics and stakeholder statements. Each initiative was coded for goals, instruments, governance, funding, accountability, and stated indicators;

cross-cutting facilitators and risks were synthesized using a directed content-analysis framework.

Results: EFour flagship policies were identified: (1) a Public Medical Academy designed to expand public-interest training pipelines for essential disciplines; (2) a Regional Doctor System that channels trainees and specialists to underserved areas through region-linked admissions, rotations, and service obligations; (3) a Regional and Essential Healthcare Fund to develop networks, capacity, and continuity of critical services; and (4) reimbursement reform that realigns prices toward high-need, after-hours, and emergency care while protecting primary-care viability. Collectively, these policies pursue regional equity and essential-care sustainability but face obstacles of inter-ministerial coordination, consistent execution across jurisdictions, long-term workforce retention under obligation schemes, and balancing compensation across levels of care.

Discussion: Reform momentum accelerated with medical-school expansion and the Essential Healthcare Support Plan, yet progress remains fragmented. Early gains are visible in selected emergency coverage and targeted fee adjustments, while durable improvements in distribution and timely access are not yet demonstrable. Stronger alignment between education, payment, and service delivery is required, supported by transparent monitoring dashboards, credible milestones, and sustained stakeholder engagement.

Conclusion: Sustained impact will require regionally accountable training pathways, value-based purchasing that rewards outcomes and continuity, and investment in housing, childcare, team-based clinics, and shared call coverage to anchor professionals locally and strengthen primary and emergency care. Together, these steps can advance more equitable national health development while consolidating essential services across regions.

ID 2145- Transforming Long-Term Condition Management Through Digital and AI-Enabled Recall: A Practical Framework for Global Primary Care

Emanuela Rachel BOCHIS, Ioana Veronica GRĂJDEANU, Ana Maria Alexandra STANESCU

Carol Davila University Of Medicine And Pharmacy, Bucharest, Roumanie

Context: Vitamin D deficiency is acknowledged as a general health concern globally, particularly among populations with limited sunlight exposure. Beyond its well-known role in musculoskeletal health, vitamin D holds a myriad of under-recognized health benefits, from cardiovascular health, immunity, brain function, to fertility and other chronic diseases. Primary care physicians play a key role in preventive health strategies, including counseling and supplementation practices. Understanding patient behaviors and beliefs is essential for improving preventive care and reducing deficiency-related complications.

Objectives: To determine the prevalence and predictors of vitamin D supplementation among adult patients attending a family medicine practice, to evaluate the supplementation behaviors and to identify opportunities for improving preventive counseling on vitamin D in family medicine.

Methods: A cross-sectional survey was conducted between November 2025 and December 2025 in a family medicine practice in Bucharest. A total of 100 consecutive adult patients attending routine consultations were invited to complete a structured questionnaire with 10 questions on vitamin D intake, sources of information and perceived benefits. Data on age, gender and comorbidities were collected from medical records. The inclusion criteria were: patients aged 18 years old and above, attending a non-emergency appointment, able to read and complete a short form. Descriptive and inferential statistical analyses will be performed to explore associations between supplementation and demographic factors. Data analysis is ongoing.

Results: (Anticipated results): Although data collection is ongoing, early patterns suggest

suboptimal adherence to vitamin D supplementation during winter. The final results are anticipated to clarify which patient groups are least likely to supplement and to highlight opportunities for improving counseling and prevention in the family medicine setting. Comprehensive findings will be presented at the conference.

Discussion: Initial observations indicate suboptimal supplementation practices among adult patients. This highlights a broader public health challenge in regions with limited sunlight exposure. Understanding patient motivations and barriers may support the development of community-level prevention strategies grounded in primary care insights.

Conclusion: Early findings suggest that vitamin D supplementation remains inconsistent among adults. Preliminary trends emphasize the importance of patient education regarding vitamin D and its health benefits. Strenghtened communication and counseling in family medicine could improve supplementation practices.

ID 67- Transforming physician mental health support: Development, implementation and impact of an innovative "Mifne" service

Eloïse ROY, Sohela MOUSSAOUI

Main, Paris, France

Context: Missed appointments affect 6 to 10% of general practice patients in France, representing approximately 27 million absences annually. The main causes include forgetfulness, personal or professional constraints, and logistical or financial obstacles. These absences more frequently affect vulnerable populations such as young people, the elderly, those in precarious situations, or those with psychiatric disorders. Current solutions are primarily punitive and could exacerbate the marginalization of these patients.

Objectives: The following study aims to evaluate a non-punitive approach to reintegration into care.

Methods: A health center in the Paris region implemented a system to remind patients who had missed their appointment with a general practitioner and offer them a new appointment within a reasonable time frame. These consultations systematically included time dedicated to screening for violence, using digital tools and educational resources for practitioners. The study targeted patients over the age of 18 who had previously consulted at the health center and missed an appointment without notice between February and September 2024. The objective of the study was to assess the proportion of violence newly identified during appointments offered to patients who had missed a general medicine appointment.

Results: A total of 287 patients missed an appointment without notice, and of these, 151 were contacted by phone to reschedule a consultation. Sixty-one patients (40.4%) accepted a second appointment, and 31 (50.8%) actually attended. During systematic screening, 61.1% of those screened (N=11), reported violence, including 63.6% (N=7) that were previously unknown to healthcare professionals.

Discussion: Despite the low sample size due to a hard-to-reach population, the program illustrates the value of a proactive approach to turning missed appointments into opportunities for intervention.

Conclusion: These results highlight the importance of improving access to care for vulnerable populations and strengthening systematic screening for violence.

ID 1439- Transforming Rural Healthcare: An Evidence-Based Review of Artificial Intelligence Applications in Telemedicine

Tânia GOMES, Ana Cremilda DURÃES, Ana LOPES GOMES

Usf São Vítor-Uls Braga, Braga, Portugal

Context: Dermatological conditions are a frequent reason for consultation in primary care. Poikiloderma of Civatte (PC) is an underrecognized cutaneous disorder characterized by chronic hyper- and hypopigmentation, telangiectasias, and superficial atrophy. Awareness of this entity is important for early recognition and appropriate management.

Methods: A 70-year-old woman with fair skin phototype and medical history of hypertension, dyslipidemia, and osteoporosis presented to primary care with one-year history of hyperpigmented macules on the anterior and posterior infracervical regions and both forearms. She denied pruritus or other associated symptoms. Physical examination confirmed reticulated hyperpigmented lesions in the neck and décolletage area, without involvement elsewhere. Laboratory and endoscopic studies ruled out secondary causes of hyperpigmentation. She was referred to dermatology, where the main differential diagnoses were lichen planus pigmentosus or post-inflammatory pigmentation due to photosensitivity. Daily topical clobetasol and strict photoprotection were prescribed. Subsequent follow-up allowed confirmation of the diagnosis of Poikiloderma of Civatte.

Originality: This case highlights an uncommon but clinically relevant dermatological entity in primary care, often misdiagnosed due to its subtle presentation and similarity to other hyperpigmentation disorders. While PC is benign, its cosmetic impact can be significant and progression is typically irreversible.

Lessons learned and future implications: Early recognition of PC allows appropriate counseling on photoprotection and management, avoiding unnecessary investigations. Clinicians should consider PC in postmenopausal women presenting with reticulated pigmentation in sun-exposed areas, especially the neck and chest.

Discussion: PC predominantly affects sun-exposed regions in fair-skinned individuals over 40 years, with higher prevalence in postmenopausal women. Etiology is multifactorial, including ultraviolet radiation, hormonal changes, contact sensitization from perfumes or cosmetics, and intrinsic aging. Diagnosis is primarily clinical, supported by histology which is characteristic but not pathognomonic.

Conclusion: Poikiloderma of Civatte is a common, acquired, benign skin disorder with progressive course. Awareness in primary care is essential to provide early management, reduce cosmetic concerns, and prevent misdiagnosis.

ID 2086- Transient Ischemic Attack after Anticoagulant Discontinuation in Atrial Fibrillation

Cristina Maria MINCU

Family Medicine Practice, Romania, Bucharest, Roumanie

Context: Inappropriate antibiotic use is one of the key drivers of bacterial resistance and remains a major challenge in primary care. In family medicine, patients' understanding of when and how antibiotics should be used is often limited, which may lead to unnecessary antibiotic requests or incorrect self-medication behaviors.

Objectives: To assess adult patients' knowledge regarding the appropriate use of antibiotics in a family medicine setting in Romania.

Methods: This cross-sectional observational study was conducted in a family medicine practice. A total of 100 consecutive adult patients, attending for various reasons, were invited to complete an anonymous five-item questionnaire (Yes/No/Don't know). The questions addressed five common misconceptions: 1. Antibiotics treat colds or flu. 2. Leftover antibiotics can be used for another illness. 3. Antibiotic treatment can be stopped once symptoms improve. 4. It is safe to take antibiotics given by someone else. 5. Misuse of antibiotics can lead to bacterial resistance. Descriptive analysis (percentages) was used to summarize correct responses and identify knowledge gaps.

Results: A considerable proportion of patients are expected to hold misconceptions regarding antibiotic use—for instance, believing antibiotics are effective against viral infections or can be stopped early. The study will identify which questions reveal the most significant knowledge deficits.

Discussion: The preliminary findings of this study suggest that misconceptions regarding antibiotic use remain common among patients in primary care. Misunderstandings such as believing that antibiotics treat viral infections or that treatment can be stopped early reflect a gap in public health education. These results are consistent with other European studies showing persistent misinformation about antibiotics despite ongoing awareness campaigns. Family doctors are in a unique position to address these gaps through brief educational messages during consultations or by distributing clear informational materials. Implementing such low-cost, targeted strategies in daily practice could significantly improve patients' understanding and reduce unnecessary antibiotic use.

Conclusion: This study highlights the current level of patients' understanding regarding antibiotic use in Romanian primary care. The findings may guide simple, targeted educational interventions in family medicine practices to promote rational antibiotic use and help reduce antimicrobial resistance.

ID 1483- Traumatic Injury of the Sigmoid Colon: A Rare Complication of a Blunt Abdominal Trauma.

Margot PRIVAT

Rouen University, Faculty Of Medicine, Lyon, France

Context: In XXXX, there is an ongoing socio-political debate regarding the legalization of medical assistance in dying (MAiD). This study aimed to evaluate XXXX general practitioners' (GPs) perceptions and attitudes of home-based end-of-life care and their potential involvement in MAiD should it become legalized.

Methods: A cross-sectional quantitative survey was conducted using a questionnaire developed from previously published qualitative studies. Participants included private practice GPs—both established and locum physicians—regardless of whether they had completed their doctoral thesis.

Originality: This study provides new quantitative evidence regarding GPs' attitudes toward MAiD, complementing existing qualitative findings and broadening understanding of physicians' perspectives on this ethically complex issue.

Lessons learned and future implications: A total of 119 completed questionnaires were analyzed between March and May 2025. Among respondents, 61% were women and 56% were aged 30–40 years. Home-based end-of-life care was relatively infrequent, 50% of physicians managing one to two patients per year and 25% reported feeling comfortable with such care. The most reported concerns were insufficient time for patient support (61%) and professional isolation (66%). If MAiD were legalized, 49% of GPs stated they would consider performing the procedure. The most important conditions cited were the absence of external pressure on patients (94%) and adequate information regarding palliative care options (88%). Physicians were more favorable toward MAiD in cases involving refractory pain (81%), amyotrophic lateral sclerosis (87%), or other neurodegenerative diseases (81%). If MAiD were legalized in XXXXX, further studies will be required to explore GPs' perceptions of its impact on their clinical practice and professional identity.

Discussion: Home-based end-of-life care provided by GPs was rare and demanding, requiring significant time commitment and personal involvement. Many physicians reported feelings of isolation and difficulties accessing external resources such as home hospitalization services or palliative care teams. Existing legislation appeared inadequate for certain cases, particularly those involving refractory suffering in patients without a short-term terminal prognosis.

Conclusion: While a majority of GPs supported the legalization of MAiD, fewer expressed willingness to personally perform the act. Each end-of-life situation warrants an individualized ethical and clinical approach, supported by multidisciplinary collaboration and appropriate legislative frameworks.

ID 138- Triglyceride–Glucose Index as a Potential Indicator of Metabolic Syndrome

Claudia Maria GOMES PIMENTEL

University Of Porto, Porto, Portugal

Context: Family Medicine strives for equity, yet health disparities are persistently driven by social determinants. Historical attitudes often reinforce these disparities, and 19th-century visual culture is a powerful medium for critiquing the origins of these systemic biases. This visual analysis addresses the critical gap in understanding how historical art can illuminate the visual stigmatization and exclusion of vulnerable patients, a crucial dimension for cultivating humanism and enhancing Narrative Medicine in Primary Care.

Objectives: This paper employs a critical visual analysis of two key 19th-century European paintings to examine historical power dynamics and the representation of social determinants of health in patient care. The goal is to draw actionable implications for contemporary Family Medicine practice by demonstrating how these visual narratives challenge the traditional medical gaze.

Methods: Using the framework of narrative competence, this paper conducts a focused visual critique of Sir Luke Fildes' The Doctor (1891) and Christian Krohg's Sick Girl (1881). The analysis categorizes findings based on compositional elements, lighting, and subject positioning to interpret themes of power dynamics, social exclusion, and the presence or absence of professional fraternity in the doctor-patient relationship.

Results: It reveals a persistent pattern of visual exclusion and historical bias. Critiques of Fildes' The Doctor illustrate a Victorian emphasis on the heroic, dominating physician ("the gaze"), relegating the poor family to the dark periphery. This underscores a paternalistic system where the "human touch" was conditioned by the patient's low social status.

Discussion: By examining Fildes' compositional choices, physicians can recognize and challenge the contemporary remnants of the "medical gaze"—the tendency to objectify the patient or overlook the power imbalance inherent in clinical interactions. Conversely, studying Krohg's work provides a visual vocabulary for understanding the weight of social factors (housing, nutrition, and income) that often constitute the real story behind a chief complaint.

Conclusion: Visual critique, anchored by art historical sources, is a powerful tool for cultivating reflexive medical practice. This paper argues that by deconstructing the "invisible patient" in these visual narratives, Family Physicians can enhance their narrative competence. This enhanced skill set fosters genuine humanism and reaffirms a commitment to health equity in modern primary care.

Marloes MINNAARD [(1)], Martijn RUITEN [(2)]

(1) Staff Member, Utrecht, Pays-Bas
(2) Medical Director, Utrecht, Pays-Bas

Context: Working as a general practitioner (GP) in a prison environment entails distinctive challenges. Incarcerated individuals frequently present with complex health problems, including substance dependence, psychiatric disorders, intellectual disabilities, and chronic conditions. Delivering care is further complicated by restricted resources and the necessity of adhering to strict security measures.

Methods: Effective prison healthcare requires continuous refinement of protocols and preventive strategies. Tailored guidelines must

be implemented to ensure that medical services adequately respond to the distinct health profiles of inmates.

Originality: Over time, prison healthcare in the Netherlands has developed into a structured, safe, and multifaceted system. A central aim is to strengthen preventive medicine and to establish guidelines that specifically address the unique needs of the prison population.

Lessons learned and future implications: GPs working in prisons must demonstrate adaptability, creativity, and a thorough understanding of legal and security frameworks. Inmate health literacy is often limited, and medical resources remain less extensive than those available in community settings, demanding innovative approaches to care.

Discussion: Illustrative case studies will be presented to highlight both the challenges and the opportunities inherent in prison healthcare.

Conclusion: The overarching objective for GPs in prisons is to guarantee that the quality of care matches that provided outside prison walls. Despite systemic constraints, it is possible to deliver high-quality, patient-centered care. By acknowledging and addressing the specific healthcare needs of incarcerated populations, GPs can uphold standards of equity and continuity within correctional facilities.

ID 1413- Type 1 diabetes mellitus: relevance of the problem; a comprehensive approach to addressing issues related to prevention and effective measures to avert the development of the disease in children born to mothers with type 1 diabetes

So Yun MIN, Chul Min KIM, Chang Ho AN, Ki Chul KIM, Jae Young PARK, Han Hee BAE

Palliative Medicine, The Catholic University Of Korea, Seoul St. Mary's Hospital, Seoul, Corée (République de)

Context: Cancer is a major cause of mortality and a leading driver of healthcare costs, ranking second in total medical expenditure in South Korea. Although hospice and palliative care improve quality of life and reduce costs, comparative evidence on end-of-life medical costs across hospice settings in Korea remains limited. Therefore, a comprehensive evaluation of hospice cost-effectiveness is needed to inform healthcare resource allocation.

Objectives: To compare end-of-life medical costs among cancer patients across home-based hospice, inpatient hospice, and general ward settings, and to assess cost differences according to place of death.

Methods: This retrospective study analyzed medical records of 1,261 cancer patients who died at a single tertiary institution between January 1 and December 31, 2022. Medical expenses were evaluated for the final 1, 3, 6, and 12 months of life using SAS 9.4. Patients were categorized into hospice and non-hospice groups; hospice users were further divided into home-based and inpatient hospice subgroups, with the home-based group additionally classified as home-death or ward-death. Secondary analyses excluded patients who died within seven days of hospice admission to minimize underestimation of hospice-related costs.

Results: Hospice users showed more than 50% lower total medical expenditures than non-hospice users across all periods ($p < 0.05$). After excluding patients who died within seven days of hospice admission, home-based hospice care consistently incurred lower costs than inpatient hospice ($p < 0.05$). Furthermore, home deaths were associated with reduced expenses compared with ward deaths, except during the 12-month pre-death interval ($p < 0.05$).

Discussion: These findings provide quantitative evidence that hospice care—particularly home-based services—significantly reduces the economic burden at the end of life. The results are consistent with international evidence showing that early hospice referral and community-based palliative care, by

maintaining continuity outside hospitals, are associated with lower costs.

Conclusion: Hospice care substantially reduces end-of-life medical expenses for cancer patients, with the greatest savings observed in home-based and home-death settings. Early hospice referral and the expansion of home-based palliative services may enhance cost-effectiveness and promote patient-centered end-of-life care for cancer patients.

ID 626- Ulceronecrotic Tonsillitis in a Young Adult: A Rare Presentation

Eunhye CHAE

Department Of Family Medicine, Gangneung Asan Hospital, University Of Ulsan College Of Medicine, Gangneung-Si, Corée (République de)

Context: In recent years, sociocultural influences and changing health awareness have contributed to growing misperceptions of body weight, leading individuals to either underestimate or overestimate their body size. Inaccurate perceptions can result in inappropriate health behaviors, delayed recognition of obesity, and psychological distress. Understanding the discrepancy between objectively measured BMI and perceived body image is essential for improving awareness and developing effective health management strategies.

Objectives: This study aimed to examine the association between BMI-based body image perception accuracy and health behaviors and mental health indicators , and to further evaluate its relationship with metabolic syndrome components within the obese subgroup.

Methods: A cross-sectional analysis of 5,504 adults aged ≥ 19 years from the 2023 National survey was conducted. Participants were classified into three groups—underestimation, accurate perception, and overestimation—based on the concordance between measured BMI and self-perceived body image. Variables included sociodemographic factors, lifestyle behaviors, mental health indicators and clinical parameters. Among obese individuals, logistic regression analyses were performed to assess the association between obesity awareness and the prevalence and odds ratios of metabolic syndrome and its individual components.

Results: The underestimation group showed higher smoking rates, lower aerobic activity, and less frequent weight control efforts compared with the accurate perception group ($p<0.01$). They also had a higher prevalence of hypertension and diabetes and showed greater proportions of moderate and high risk hs-CRP levels. ($p<0.01$) The overestimation group exhibited higher anxiety scores and lower perceived health despite greater attempts at weight reduction. Among obese adults, unawareness of obesity was independently associated with increased odds of metabolic syndrome prevalence, abdominal obesity, hypertension, and hypertriglyceridemia compared with those who recognized their obesity ($p<0.01$).

Discussion: Underestimation of body weight was linked to adverse metabolic profiles and unhealthy lifestyle patterns, suggesting that individuals unaware of their obesity may fail to engage in preventive behaviors. Overestimation, in contrast, was associated with psychological distress, emphasizing the dual burden of both types of misperception.

Conclusion: Improving accuracy of body weight perception may promote healthier behaviors and reduce the risk of metabolic complications. In primary care, targeted strategies to enhance self-awareness could be beneficial for managing obesity.

Context: Reti-CVD is a deep learning-based algorithm that estimates cardiovascular

disease (CVD) risk through analysis of retinal fundus images. As a non-invasive and accessible tool that does not require blood tests or radiation exposure, it has gained interest as a novel screening method.

Objectives: This study aimed to investigate the relationship between Reti-CVD scores and coronary artery calcium scores (CACS), and to evaluate predictive differences according to body mass index (BMI) using subgroup analysis in a health screening population.

Methods: A retrospective cross-sectional study was conducted on 147 adults who underwent both retinal imaging and coronary CT at a university hospital in XXX Province, XXX, in 2024. Reti-CVD scores were calculated using a deep learning model based on retinal images. CACS was binarized: a score of 0 was defined as the non-calcified group, and ≥1 as the calcified group. Covariates included hypertension, DM, dyslipidemia, waist circumference, BMI, SBP, DBP, HbA1c, liver enzymes, renal markers and lipid profiles.

Results: The presence of coronary artery calcium was significantly associated with higher Reti-CVDscores (β = 3.84, p = 0.014). Hypertension (β = 3.69, p = 0.029) and systolic blood pressure (β = 0.21, p = 0.006) were also significant predictors. In subgroup analysis, participants with BMI ≥ 25.0 (n = 66) showed a stronger association between CACS and Reti-CVD (β = 6.03, p = 0.012). In contrast, the BMI < 25.0 group (n = 81) showed no significant association between CACS and Reti-CVD (p = 0.131), while SBP, DBP, and BMI remained significant predictors.

Discussion: The Reti-CVD score demonstrated a significant association with coronary artery calcium, particularly in overweight and obese individuals, suggesting that it reflects structural vascular changes. The observed associations with hypertension and blood pressure support the hypothesis that retinal microvascular changes correlate with systemic vascular health.

Conclusion: Reti-CVD was more sensitive to coronary calcification in individuals with higher BMI, indicating that this algorithm maybe especially useful in identifying high-risk groups. These findings support the potential of Reti-CVD as an adjunctive tool for early risk stratification and clinical decision-making. Reti-CVD may serve as a scalable biomarker for cardiovascular screening in both primary care and health screening settings.

Bo Kyung SHINE

1department Of Family Medicine, College Of Medicine, Dong-A University, Busan, Corée (République de)

Context: Schisandra chinensis has traditionally been recognized for its anti-inflammatory and antioxidant. Recent studies have further suggested its potential benefits for joint health, indicating that it may help protect cartilage and reduce inflammation-related discomfort.

Objectives: This study aimed to evaluate the efficacy and safety of oral Schisandra chinensis extract supplementation in improving joint and cartilage health among adults experiencing knee discomfort.

Methods: In this randomized, double-blind, placebo-controlled trial, 70 participants aged 40–75 years with knee joint discomfort were enrolled. Participants were randomly assigned to receive either Schisandra chinensis extract (1,000 mg/day; 500 mg twice daily) or a placebo for 8 weeks. The primary outcome was change in the Visual Analogue Scale (VAS) score. Secondary outcomes included changes in the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) and inflammatory biomarkers (CRP, ESR). Safety was evaluated through vital signs, laboratory tests, and adverse event monitoring.

Results: In the intention-to-treat (ITT) analysis, the treatment group showed a greater reduction in VAS than placebo (p=0.021), and WOMAC also improved significantly (p=0.035), with no serious adverse events.

Discussion: Eight weeks of oral Schisandra chinensis extract supplementation appears to be effective and safe for improving joint symptoms in adults with knee discomfort. These results are consistent with the traditional anti-inflammatory and antioxidant properties of Schisandra chinensis and suggest its potential to support cartilage protection and joint function. The improvement observed may be related to modulation of inflammatory pathways and oxidative stress, although the exact mechanisms require further investigation.

Conclusion: Schisandra chinensis extract supplementation shows promise as a functional ingredient for joint health. Further long-term and large-scale studies are warranted to confirm its clinical efficacy and elucidate the underlying mechanisms.

ID 503- Understanding health beliefs among women in developed and developing nations: a comparative survey study in XXX and YYY

Mitesh SHAH

Singhealth Polyclinics, Singapore, France

Context: Team-based care is vital in primary care where patients often have complex medical and psychosocial needs. However, medical undergraduates frequently struggle to appreciate how healthcare professionals collaborate to deliver coordinated, patient-centred care, despite participation in traditional student sit-ins at individual service stations at our primary care clinics.

Methods: Each year, eight batches of 18 medical undergraduates from the National University of Singapore undergo primary care rotations in our clinics. Previously, students observed various team members providing one-to-one care, followed by theoretical discussions. From June 2025, the teaching approach was redesigned to include: (1) a nurse preceptor-led briefing on team-based care; (2) continued sit-ins with nurses and allied health staff; (3) a two-hour allied health–led teaching session on professional roles in primary care; and (4) role-play sessions with pre-crafted scenarios followed by debriefing, replacing didactic discussions. Pre- and post-implementation feedback was collected and analysed.

Originality: This method of instruction has not been used before.

Lessons learned and future implications: Albeit more effort is needed to get the tutors from different domains to come together and teach the module, the results show that the undergraduates were better able to appreciate team-based care for holistic care of our chronic care patients. Gathering domain tutors for every batch of students was initially difficult, but when they eventually saw the benefit of modular teaching on this subject.

Discussion: Students reported markedly improved understanding of team-based care concepts and clearer appreciation of the distinct and complementary roles of healthcare professionals. They found the role-play simulations more engaging and relevant compared to passive observation. Tutors from multiple disciplines noted stronger student participation and insight during debriefings. Pre- and post-implementation surveys further confirmed the better appreciation of team-based care.

Conclusion: A structured, experiential teaching approach incorporating preceptor briefings, allied health teaching, and interprofessional role-play significantly enhanced medical students' appreciation of team-based care in primary care settings. This model, though resource-intensive, offers a replicable framework for other undergraduate training programs.

ID 814- Understanding Student Health Needs at a Multidisciplinary University in XXX: A Three-Year Retrospective Analysis of Health Service Utilization

Mir JUN

Yeoido St. Mary's Hospital, Seoul, Corée (République de)

Context: Diet is a key modifiable risk factor for non-communicable diseases, yet evidence linking macronutrient intake to mental health—particularly anxiety—remains limited. Understanding these associations may provide insight into potential preventive strategies.

Objectives: This study examined the association between macronutrient-based dietary patterns and mental health outcomes, including moderate-to-severe anxiety and suicidal ideation, and explored potential sex-specific differences using nationally representative data.

Methods: We analyzed 9,002 adults aged ≥19 years from the 2021–2023 Korea National Health and Nutrition Examination Survey. Dietary patterns were categorized as normal, high-carbohydrate (HCHO), high-fat (HF), or high-protein (HP) based on macronutrient energy proportions. Anxiety was assessed using the GAD-7 (≥10), and suicidal ideation was identified through self-report. Complex-survey logistic regression with sequential covariate adjustment was employed, including sex-stratified models.

Results: Dietary patterns were not associated with suicidal ideation. However, individuals in the HP group had significantly lower odds of moderate-to-severe anxiety compared with the normal-diet group (adjusted OR 0.49, 95% CI 0.30–0.81). In sex-stratified analyses, this inverse association remained significant only in men (OR 0.23, 95% CI 0.09–0.60). No significant associations were observed in women. Higher anxiety scores were strongly associated with suicidal thoughts, planning, and attempts.

Discussion: The association between high protein intake and lower anxiety may relate to increased availability of amino acids involved in neurotransmitter synthesis and stress regulation. The stronger effect observed in men suggests possible sex-specific metabolic or hormonal influences. However, the cross-sectional design limits causal interpretation, and dietary quality within macronutrient categories was not evaluated. Despite these limitations, the findings indicate that dietary composition—particularly protein intake—may be a modifiable factor linked to anxiety risk.

Conclusion: High-protein dietary patterns were associated with reduced odds of moderate-to-severe anxiety among Korean adults, especially men. Although no relationship was found between dietary patterns and suicidal ideation, the strong association between anxiety severity and suicide-related behaviors highlights the importance of identifying modifiable contributors to anxiety. Longitudinal studies are needed to clarify causality and underlying mechanisms.

ID 1841- Understanding Vulnerability to Homicides of Adolescent Females from the Perspective of Virtual Violence and Intersectionality

Wonsock KIM

Uijeongbu Eulji Medical Center, Eulji University School Of Medicine, Uijeongbu, Corée (République de)

Context: Understanding frailty is the key to identifying and predicting the health status of the older adults. The Frailty Index , which utilizes an accumulation of various variables , is very useful in predicting a patient's health status as changes in the degree of frailty can be monitored.

Objectives: It remains unclear whether the frailty index has a meaningful predictive value for major outcomes such as mortality and intensive care unit (ICU) admission. Therefore, the author aimed to investigate the association between the frailty index and major outcomes based on nationwide cohort data from the Korean population.

Methods: A total of 135,581 individuals who requested long-term care between 2009 and 2012 were enrolled in the study, and were followed-up until the end of 2020. A deficit-accumulation frailty index (range: 0–1; robust <0.15, pre-frail 0.15–0.24, mild-to-moderately frail 0.25–0.44, severely frail ≥0.45) was calculated using 41 variables at enrollment. Hazard ratios (HRs) and 95% confidence intervals (CI) were calculated using multivariate-adjusted Cox proportional hazards regression analysis.

Results: During the 6.30 years of follow-up, 92,336 cases of mortality were recorded. After adjustment, the HRs (95% CI) for mortality, compared to the robust group, were 1.27 (1.22−1.33) in the pre-frail group, 1.61 (1.55−1.67) in the mild-to-moderately frail group, and 2.32 (2.23−2.41) in the severely frail group (p for trend <0.001). Additionally, during the 5.49 years of follow-up for ICU admission with 40,070 cases, The HRs (95% CI) for ICU admission were 1.18 (1.11−1.26) in the pre-frail group, 1.39 (1.32−1.46) in the mild-to-moderately frail group, and 1.81 (1.72−1.90) in the severely frail group (p for trend <0.001).

Discussion: A significant increasing association depending on the stage of frailty according to FI was confirmed in our study (p for trend <0.001). Through this study, we confirmed that the HRs for mortality and ICU admission increased proportionate to the degree of frailty.

Conclusion: In this large-scale nationwide cohort study of older adults, frailty was significantly associated with increased risks of mortality and ICU admission according to frailty stages measured by frailty index. It seems that the frailty index provides additional value in predicting severe major outcomes such as mortality and ICU admission.

(2) Clalit, Tel Aviv, Israël

Context: Transgender and gender-diverse people continue to face major barriers in accessing primary healthcare, often due to lack of knowledge, assumptions, and systemic gaps within family practice settings. Family physicians serve as the first and sometimes only point of contact for this population, yet many report uncertainty in communication, hormone management, and preventive care. This workshop, led by three family physicians from Tel Aviv experienced in gender-affirming medicine, aims to equip participants with the knowledge, skills, and practical tools to provide inclusive and affirming care.

Objectives: • Recognize the unique health needs and barriers faced by transgender and gender-diverse patients. • Develop communication skills that foster trust and respect during clinical encounters. • Gain confidence in managing hormone therapy, preventive care, and multidisciplinary coordination. • Design practical steps toward building trans-friendly approaches within everyday family practice.

Teaching method and workshop: The workshop will be highly interactive, combining short, evidence-based presentations, small-group work, and experiential learning. • Mini-lecture: Overview of trans health inequities and key international guidelines. • Small-group case discus

Expected outcomes: Participants will gain practical, evidence-based skills to provide gender-affirming care, enhanced confidence in communication, and a clear understanding of where to intervene along the patient journey. The session promotes empathy, reflection, and a

Conclusion: This workshop offers a space for reflection, empathy, and skill-building, empowering family physicians to become advocates for equitable, humanistic, and gender-affirming primary care. Participants will leave with both practical tools and renewed confidence to make every clinical encounter more inclusive.

ID 1616- Unexpected Marked LDL-C Elevation in the Setting of Extensive Liver Metastases: Possible Pseudo-Hypercholesterolaemia

Wenjia XU

Singhealth Polyclinic, Singapore, Singapour

Context: Facial pain is a rare but potentially debilitating condition that can be a diagnostically challenging presentation in primary care. Early recognition of trigeminal

neuralgia is paramount to prevent prolonged suffering and unnecessary treatment. Here we present a case which highlights the importance of interprofessional collaboration, structured clinical reasoning, and pharmacogenetic considerations in managing neuropathic pain in a primary care setting.

Methods: A 56-year-old Chinese woman with hypertension, hyperlipidaemia and type 2 diabetes, presented with a one-month history of sharp, shooting right brow pain which radiates along the ophthalmic (V1) branch of the trigeminal nerve. Pain was triggered by wind and light touch, not relieved by pregabalin and lorazepam prescribed elsewhere. Physical examination was unremarkable. Based on the history and examination, a clinical diagnosis of trigeminal neuralgia was made. Given the patient's Asian ethnicity, she was referred to a neurologist for consideration of carbamazepine and HLA-B*1502 testing to avoid severe cutaneous reactions. Amitriptyline 10 mg nightly was prescribed for interim symptomatic relief. Magnetic resonance imaging (MRI) of the brain subsequently confirmed neurovascular compression of the right trigeminal nerve. The neurologist started the patient on carbamazepine after negative allele testing, and neurosurgery advised continued medical therapy.

Originality: This case highlights the important role of family physicians in recognizing uncommon neurological disorders and initiating safe, evidence-based management. While trigeminal neuralgia is well-described in literature, reports focusing on its identification and genetic testing implications in Asian primary care populations remain limited.

Lessons learned and future implications: Early identification of trigeminal neuralgia in primary care relies on meticulous history-taking and awareness of its characteristic pain distribution. Integrating pharmacogenetic testing into prescribing decisions demonstrates personalised, culturally sensitive care. Strengthening coordination between family physicians, neurologists, and neurosurgeons ensures timely diagnosis and optimal outcomes.

Discussion: This case reinforces the educational value of clinical reasoning and multidisciplinary coordination of care between family physicians and other specialists to provide holistic patient-centred care.

Conclusion: Family physicians play a pivotal role in early detection and safe management of trigeminal neuralgia through patient-centred, and collaborative care. Compassionate listening, shared decisions, and culturally informed prescribing reflect the humanistic values that define high-quality primary care.

ID 618- Unexplained Left Ventricular Hypertrophy Revealing Transthyretin Cardiac Amyloidosis: A primare Care-Driven Diagnosis

Raquel GRACIA-RODRÍGUEZ [(1)] , Raisa ALVAREZ-PANIAGUA [(2)]

(1) U.g.c. Bujalance, Córdoba, Espagne
(2) C.s. Cervera Del Río Alhama, La Rioja, Espagne

Context: Thyroid ultrasound has proven to be a highly valuable diagnostic tool when performed directly in primary care. Although hypothyroidism and thyroid disorders are often considered functional diseases, ultrasound enables rapid and non-invasive identification of structural abnormalities that can guide the etiological diagnosis and help rule out more serious conditions. Thyroid ultrasound can reveal chronic thyroiditis (CT) in up to 34% of patients with negative serological studies but histologically proven disease. In recent decades, the diagnosis of thyroid cancer—particularly papillary carcinoma—has increased significantly due to the widespread use of imaging techniques such as ultrasound.

Methods: We present the case of a 40-year-old woman who consulted for a right anterior cervical lump she had noticed four days earlier. She reported no weight loss or pain on palpation, and the lump was mobile when swallowing. Her family physician ordered routine blood tests and a thyroid ultrasound. The blood results were completely normal, but the ultrasound appointment had not yet been scheduled. Since I regularly perform

ultrasounds in my practice, I performed one during the consultation. The thyroid gland showed an irregular structure suggestive of chronic thyroiditis. A teleconsultation with the endocrinologist was requested to review the images and confirm the diagnosis, leading to early management.

Originality: The originality of this case lies in the practical application of ultrasound within the family medicine setting, where such resources are not routinely available. Performing point-of-care ultrasound (POCUS) in the office demonstrates how this tool enhances diagnostic accuracy, improves resource utilization, and strengthens continuity of care.

Lessons learned and future implications: This case highlights the need to incorporate thyroid ultrasound into the initial diagnostic approach in primary care, particularly in patients presenting with cervical masses or suspected thyroid dysfunction. Point-of-care imaging facilitates early detection of chronic thyroiditis, timely referral, and better patient reassurance.

Discussion: In this case, despite normal lab results and no alarming clinical signs, ultrasound revealed glandular changes consistent with chronic thyroiditis.

Conclusion: This enabled early referral and timely treatment, avoiding diagnostic delays and uncertainty. Immediate in-office ultrasound improved differential diagnosis and coordination with endocrinology, highlighting its value in enhancing diagnostic accuracy, physician autonomy, and efficient, patient-centered primary care.

(1) U.g.c. Bujalance, Córdoba, Espagne
(2) C.s. Cervera Del Rio Alhama, La Rioja, Espagne

Context: Sarcomas are tumors that represent 1% of all malignant neoplasms in adults. Despite well-defined referral guidelines, the diagnosis of sarcoma is often delayed, due to the rarity of the disease and inconspicuous presentation, as well as other patient- and physician-dependent factors.

Methods: A 58-year-old male patient underwent minor surgery for a fibroid (2017) on the anterior aspect of the left thigh. Investigating the patient's medical history, the pathological anatomy of the removed piece is not found. In 2018, the patient came again because the fibroid had reappeared, being painful on palpation and presenting a purplish color suggestive of a keloid. It is treated with topical treatment without improvement. He consulted again a year later, 2019, for the same symptoms. Physical examination: tumor of about 2 cm in the left thigh Evolution: Due to the persistence of the symptoms and the slow growth of the lesion, the patient was referred to the surgery service for evaluation. During the consultation, he suggests that it is a sebaceous cyst, but it was removed in 2020 and the lesion was sent for analysis. The pathological study describes a leiomyosarcoma measuring approximately 7 cm that affects the resection edges.

Originality: - Limited knowledge of the subject - The rarity of the disease.

Lessons learned and future implications: In Spain, there are no specific guidelines for these tumors, although there are general guidelines for tumorous lesions. By reviewing these clinical cases, we are conducting a doctoral thesis on the knowledge of family doctors about these tumors in order to develop training courses, protocols, and specific units for these types of tumors.

Discussion: Sarcoma must be managed by qualified professionals who achieve early diagnosis and treatment and are referred to expert reference centers. This management has a considerable time-dependent impact on the prognoses of these patients.

Conclusion: For many years, cancer care has focused primarily on improving survival rates. Now, there is increasing emphasis on

prevention, early diagnosis, long-term survivor care, and end-of-life care. Because of this, primary care is poised to play a crucial role due to its capacity to provide comprehensive, person-centered, longitudinal, and accessible care.

ID 1914- Unintentional Weight Loss Attributed to Anxiety in Primary Care: Hyperthyroidism Revealed Through Targeted Reassessment

Andrea FÜLEOVÁ

Gp Clinic, Bidovce, Slovakia, Košice, Slovaquie

Context: Acute coronary syndrome (ACS) is a common but diagnostically challenging condition in general practice. Its clinical presentation is often atypical or subtle, which can delay recognition. Late diagnosis or inappropriate management may result in poor outcomes and medico-legal consequences. Enhancing diagnostic skills in primary care is essential to ensure timely treatment and patient safety.

Methods: This report presents case studies of patients diagnosed with ACS in a general practice setting. Point-of-care testing (POCT) for cardiac biomarkers and electrocardiogram (ECG) recordings were performed directly in the outpatient clinic. The diagnostic process, clinical decision-making, and referral to specialized cardiology centers were analyzed. Current best-practice recommendations for ACS management in primary care are summarized. The cases illustrate varied presentations and highlight the role of rapid diagnostics in improving care.

Originality: These cases show that POCT and ECG are useful tools for general practitioners. The new point is that fast testing can directly improve patient outcomes. Finding problems early in primary care shortens the time from first contact to treatment, and lowers the risk of complications. Using these tests correctly in daily practice can greatly improve patients' chances of recovery.

Lessons learned and future implications: Timely use of POCT and ECG directly enhances quality of care and patient safety. General practitioners should be trained in rapid cardiovascular diagnostics and interpretation of test results. Future efforts should focus on wider implementation of POCT, structured GP training, and increased awareness of early intervention in suspected ischemic conditions. These measures can improve early diagnosis, reduce treatment delays, and enhance overall clinical outcomes.

Discussion: Early and accurate diagnosis of ACS in primary care remains central to effective pre-hospital management. Integration of POCT and ECG allows GPs to identify high-risk patients, initiate appropriate actions, and ensure timely referral. These practices support well-coordinated regional networks for acute cardiac care and improve patient outcomes.

Conclusion: Systematic use of ECG and POCT improves the diagnostic efficiency of general practitioners managing suspected ACS. It shortens the time to treatment and contributes to better patient outcomes within a collaborative healthcare system

Context: Gender and racial inequalities in access to and utilization of health services are shaped by multiple factors, including professional practices and the availability of targeted care strategies. Effective procedures for welcoming patients and identifying the

specific needs of these populations are essential to ensure quality care. However, the intersection between race/ethnicity, gender, and tobacco use remains underexplored in Latin America, including Brazil.

Objectives: To analyze population data on tobacco, use in Brazil, categorized by race and gender, and to examine access to Primary Health Care (PHC) services, with emphasis on smoking cessation programs and harm reduction strategies. Additionally, to map the existing literature on the intersections of race, gender, and access of LGBTQIA+ populations to PHC services.

Methods: This was a descriptive cross-sectional study using data from the 2023 Vigitel survey, considering variables related to tobacco use, race, gender, and access to health services. The quantitative analysis was complemented by a narrative literature review on healthcare access among LGBTQIA+ populations and racial intersections.

Results: The prevalence of adult smokers was 9.3% (11.7% among men and 7.2% among women). The use of electronic cigarettes was reported by 2.1% of participants (2.9% men and 1.4% women), despite their illegal marketing in Brazil. Regarding self-rated health, 6.0% reported a poor condition; hypertension (27.9%) and diabetes (10.2%) were the most frequently reported chronic diseases. Notably, 72.9% of individuals living below the poverty line self-identified as Black, revealing an overlap between socioeconomic and racial vulnerabilities that may limit access to smoking cessation and harm reduction strategies.

Discussion: Despite significant advances in tobacco control, structural inequalities related to race, gender, and sexual orientation persist, influencing both consumption patterns and access to treatment. The scarcity of detailed population data continues to hinder the development of culturally sensitive and equitable public health strategies.

Conclusion: The inclusion of race, gender, and sexual orientation dimensions in epidemiological studies and public policies is essential for promoting equitable care strategies that incorporate cessation and harm reduction approaches with sensitivity to social and cultural contexts. Policies grounded in social justice, diversity, and comprehensive care are crucial to reducing historical inequalities and strengthening Primary Health Care.

ID 1046- Unmasking Primary Hyperparathyroidism Through Elderly Screening: A Primary Care Case Featuring Severe Osteoporosis

Sehong KIM, Juhye CHUNG

The Catholic University Of Korea, Seoul, Corée (République de)

Context: Sarcopenia, an age-related loss of skeletal muscle mass and strength, increases the risk of adverse health outcomes and socioeconomic burden; however, the metabolic causes of sarcopenia are unclear.

Objectives: This study investigated the association between plasma metabolites and incident sarcopenia and evaluated their predictive value for the incidence of sarcopenia.

Methods: This prospective cohort study included 33,797 participants aged 40-69 years from the UK Biobank who were free of sarcopenia and had plasma metabolomic data available. Plasma metabolite levels, including amino acids, fatty acids, lipid/lipoprotein subclasses, creatinine, and glycoprotein acetyls, were measured using nuclear magnetic resonance-based profiling. Incident sarcopenia was defined using the ICD-10 codes or criteria for low skeletal muscle mass and muscle strength.

Results: During a follow-up period of over 14 years, 829 participants developed sarcopenia. Of the 249 metabolites tested, 38 were significantly associated with the incidence of sarcopenia. The area under the ROC curve (AUC) of sarcopenia incidence for the 38 metabolites was 0.696 (95% CI: 0.666-0.726), and the AUC for conventional risk factors was 0.738-0.892, according to the models. The combined model, which integrated

conventional risk factors and metabolites, significantly improved prediction (AUC: 0.779-0.898).

Discussion: This study identified 38 plasma metabolites associated with incident sarcopenia. Incorporating these metabolites into models with conventional risk factors yielded statistically significant improvements in prediction beyond that of conventional factors alone; however, the gain was modest, and its clinical relevance remains to be determined. These findings suggest that although the clinical utility of these metabolites for predicting sarcopenia incidence has not yet been fully established, they may nevertheless provide insights into underlying biological pathways and could contribute to the development of preventive or therapeutic strategies in geriatric care.

Conclusion: This prospective study identified multiple plasma metabolites significantly associated with the incidence of sarcopenia in a large community-based cohort. Incorporation of these metabolites into predictive models significantly improved the accuracy of sarcopenia risk prediction beyond conventional factors.

ID 2236- Unnecessary access to the Emergency Room: role of General Practice

Aurélien FALCON, Pierrik FAURE

Ujm, Saint Etienne, France

Context: Osgood-Schlatter disease (OSD) is a common traction apophysitis of the tibial tuberosity in adolescents, typically associated with sports participation and repetitive strain of the patellar tendon. Despite its frequency, current management is largely empirical, relying on expert consensus rather than high-level evidence. Since 2018, several studies have explored new conservative and minimally invasive treatments, yet their methodological quality and clinical relevance remain uncertain.

Objectives: To update and synthesize current evidence on the effectiveness of non-surgical treatments for Osgood-Schlatter disease, to assess methodological quality using validated Cochrane tools, and to determine whether recent studies provide stronger evidence supporting a specific therapeutic strategy.

Methods: A systematic literature review was conducted following the PRISMA guidelines and registered in PROSPERO (CRD420251028687). All studies evaluating non-surgical interventions for OSD were included without language restriction, provided they reported at least one relevant clinical outcome (pain, symptom duration, return to sport, functional recovery, or quality of life). The databases searched included PubMed, Embase, CENTRAL, and Medline, complemented by grey literature. The risk of bias was assessed using the Cochrane tools ROB 2 (for randomized trials) and ROBINS-I (for non-randomized studies).

Results: Among 3,491 records identified, 16 original studies published between 1948 and 2022 met the inclusion criteria, involving 1,162 patients. Four double-blind randomized controlled trials assessed subpatellar injections of dextrose plus lidocaine versus lidocaine alone, with conflicting results. Twelve non-randomized studies investigated various conservative treatments—rest, stretching, physiotherapy, taping, nonsteroidal anti-inflammatory drugs, shockwave therapy, platelet-rich plasma, and immobilization—showing heterogeneous designs and high risk of bias.

Discussion: Overall, the methodological quality of available studies remains low. Only injective approaches have been evaluated through randomized trials, but none compared invasive versus conservative modalities. Evidence supporting traditional conservative management remains indirect but consistent with expert recommendations. The heterogeneity of study populations and outcome measures limits comparability and meta-analytic synthesis.

Conclusion: Current evidence on non-surgical management of Osgood-Schlatter disease remains weak. Classical conservative measures—activity modification, stretching, muscle strengthening, and taping—should

remain first-line approaches (recommendation grade C). Future high-quality comparative trials are needed to assess the true effectiveness of these non-invasive therapies and guide standardized treatment protocols.

ID 1484- Unnoticed intrauterine device migration into the pelvis: a case report

Slavica CONIC

Health Center Dr Simo Milosevic, Belgrade, Serbie

Context: The thyroid gland acts as an internal thermostat and the main regulator of metabolism. In addition to functional disorders, the pathological morphology of the thyroid is a serious problem, from micronodous, polynodous goiters to carcinoma (Ca). Women suffer from thyroid autoimmune diseases 5-10 times more often than men, and 3 times more often from malignancies.

Objectives: The aim of the study is to examine the frequency of thyroid disease in men, according to the type of pathology in a random sample; to determine the frequency of Ca thyroid; to determine the frequency of Ca thyroid patients with smoking status and according to BMI (body mass index).

Methods: Men, older than 50 years of age, were randomly selected, regardless of clinical findings, and underwent ultrasound and hormonal status.

Results: The total number of subjects was 40 (N-40). Based on this, they were divided into groups: n1(10 subjects) - morphological pathological findings, functional pathological findings; n2 (16 subjects) morphological pathological findings, normal thyroid function; n3(2) morphologically normal findings, functionally pathological; n4(12). morphologically and functionally normal thyroid. According to BMI values, 3 subjects were of normal nutrition; 2 were obese, and the rest had an increased body mass (35/ 87.5%). Five subjects used cigarettes. After the diagnosis, aspiration biopsy (FNA) was indicated in 12 (30%) subjects, and according to the results of the said diagnosis, surgical intervention was performed in 6 (15%) subjects, of whom 4 (10%) were diagnosed with carcinoma; 2 (5%) underwent thyroidectomy (benign characteristics) Among the subjects with a malignant outcome, there was not a single smoker.

Discussion: Diseases of the thyroid gland are not rare in men.The incidence of serious disorders, such as cancer and other morphological pathology that requires monitoring and even operative treatment, is statistically significant in a small sample. Subjects in whom cancer was diagnosed by screening were asymptomatic.

Conclusion: Considering the incidence of the disease by gender, screening diagnostics in men is not common. Considering the results of this study with the outcome of early detection of cancer without dissemination, screening diagnostics should be carried out regardless of gender in the elderly population

Lena EVEN [(1)] , Jean-Francois MICHEL [(2)]

(1) Independent General Practitioner, Luxembourg, Luxembourg
(2) Université Du Luxembourg, Luxembourg, Luxembourg

Context: Continuing medical education (CME) is a professional duty and a legal requirement for physicians in many European countries. However, in Country XXX, no structured national framework for CME accreditation, evaluation, or financial support currently exists. Understanding current CME practices is essential to guide the development of an effective and equitable system.

Objectives: This study aimed to describe the CME activities, preferences, and perceived challenges among general practitioners (GPs) in Country XXX, and to identify priorities for improving the national CME framework.

Methods: A descriptive cross-sectional survey was conducted between March and April 2025 among registered GPs in Country XXX. Data

were collected through an anonymous online questionnaire including closed and open-ended questions. Quantitative data were analysed using descriptive statistics, while free-text responses provided qualitative insights into individual experiences and expectations.

Results: A total of 174 GPs completed the survey, representing a substantial proportion of the national GP population. Most participants engaged regularly in CME, combining various formats such as face-to-face events, digital learning, and self-directed study. While in-person education remained central, digital formats and self-study units were increasingly valued for their flexibility. Scientific independence from pharmaceutical sponsorship emerged as a key quality criterion. Participants reported several barriers of the current system, including insufficient thematic diversity, lack of centralized coordination and accreditation, limited visibility of existing opportunities and absence of financial support.

Discussion: CME among GPs in Country XXX is widely practiced and marked by a growing diversity of learning formats. However, significant structural gaps remain. The findings underline the need for a more coherent national strategy that guarantees independence, transparency, and equitable access to high-quality CME.

Conclusion: A national CME framework, featuring accreditation, quality assurance, and a central digital platform, would help integrate CME as an inherent part of professional practice. Reinforcing these structures is crucial to sustain medical competence, foster continuous professional development, and enhance patient-centred care.

ID 97- Updating of a Knowledge Agenda using an innovative online methodology directly involving General Practitioners combined with a invitational conference

Maria PORTELA [(1)] , Indira ISLAS [(2)], Jordan HERRING [(3)]

(1) George Wasington, Washington Dc, États-Unis
(2) National Hispanic Medical Association, Washington Dc, États-Unis
(3) Sttanford, California, États-Unis

Context: Across XXX, primary care relies heavily on immigrant clinicians—family physicians, nurse practitioners, and aides who sustain access in communities that would otherwise go without. Yet the very people who keep clinics open often face the narrowest pathways to leadership, fair pay, and professional belonging. This study quantifies their contribution and the inequities that persist within the workforce they help sustain.

Objectives: To describe the scope, distribution, and advancement of immigrant clinicians in XXX primary care and to examine disparities in compensation and leadership representation compared with locally born peers.

Methods: We analyzed pooled workforce microdata from XXX covering the period 2003–2023. Variables included occupation, work hours, region, gender, earnings, and supervisory roles. Weighted regression models adjusted for education, hours, and geography to estimate adjusted odds of leadership and pay gaps. Sub-analyses explored gender and region-of-birth differences.

Results: Immigrant clinicians comprised roughly one-third of the primary-care workforce and were over-represented in safety-net and shortage areas. After adjustment, they earned less and held fewer leadership roles than locally born counterparts despite equivalent hours and qualifications. Gender and region-of-birth stratification revealed compounded inequities: immigrant women experienced the steepest gaps. Workforce diversity aligned closely with local patient demographics, underscoring a missed opportunity for language and cultural concordance.

Discussion: Findings highlight a paradox: the same clinicians bridging national access gaps face systemic barriers that limit their own advancement. Equity in recognition, compensation, and leadership is not only a matter of fairness but of health-system resilience.

Conclusion: Primary care in XXX depends on global talent, yet the structures governing that talent remain exclusionary. Policies that streamline credentialing, modernize visa pathways, value linguistic and cultural labor, and track equity metrics in pay and promotion could transform this dependence into shared belonging. Keywords: workforce diversity; immigrant clinicians; primary care; underserved areas; equity; leadership

ID 1834- Urban–Rural Differences in Depression Severity Among Patients with Type 2 Diabetes in Primary Care

Tom COLLICOTT, Santhi BETHAPUDI, Christopher JOHNSON

Durham West Primary Care Network, Nhs England (north East And North Cumbria), Durham, Royaume-Uni

Context: Artificial intelligence (AI) is increasingly entering clinical workflows through transcription and documentation systems, often referred to as “AI scribes.” In UK general practice, these tools promise to reduce administrative burden and support clinician focus during consultations. Their introduction, however, raises complex questions about safety, accountability, governance, and patient trust.

Objectives: To explore the governance, ethical, and professional framework surrounding the implementation of AI scribe technology within UK general practice, and to examine whether AI represents an emerging and likely development in the delivery of primary care.

Methods: A narrative literature review and policy synthesis were undertaken. Data sources included published NHS digital governance frameworks, clinical safety standards (DCB0129/0160, DTAC), regulatory and professional guidance (RCGP, MHRA), and evaluation reports of AI scribe deployment in general practice. Key themes were identified around safety, data protection, consent, and clinical accountability.

Results: AI scribes demonstrate potential to improve documentation efficiency and clinician workload management. However, consistent governance frameworks, data protection clarity, and transparent patient communication are essential. Risks identified include misinformation (“AI hallucination”), variable data handling practices, and ambiguity regarding legal bases for data processing. Existing regulatory standards were not designed for adaptive AI systems, creating uncertainty around liability and consent processes.

Discussion: While AI scribes align with the NHS Long Term Plan and broader priorities for digital transformation in UK primary care, their adoption must remain clinician-led, ethically governed, and evidence-informed. The current infrastructure for risk management and data governance requires adaptation to reflect AI-specific challenges.

Conclusion: The integration of AI into general practice appears increasingly likely but must be approached cautiously and with appropriate oversight. Safe and effective implementation will depend on the evolution of clinical governance and safety standards, independent validation mechanisms, and ongoing engagement with both clinicians and patients. AI scribes should be viewed as tools that augment, not replace, clinical judgment.

Context: Preservation of muscle mass during aging reduces the risk of frailty and age-related chronic diseases. Preservation of muscle mass during aging reduces the risk of frailty and age-related chronic diseases.

Objectives: We aimed to evaluate lifestyle factors and common cardiometabolic diseases as possible predictors of accelerated muscle loss in middle-aged and older men.

Methods: Men aged 40 years and older who underwent health examinations at a tertiary care hospital in Korea in 2010-2011 and after a 6-year follow-up were included in the study. Lifestyle and health status were evaluated through a standardized questionnaire. Body composition including muscle mass was estimated using bioelectrical impedance analysis. Relative change in appendicular muscle mass (ASM) was calculated as the difference in ASM between the baseline and follow-up. Accelerated muscle mass loss was defined when ASM decreased greater than 3% for 6 years. Logistic regression analysis was executed to examine the association of muscle mass loss with lifestyle factors and common cardiometabolic diseases.

Results: A total of 2,270 men aged 40 years and older were included in this study. The number of participants with ASM loss more than 3% for 6 years was 467 (20.6%). Diabetes mellitus was associated with accelerated muscle mass loss after adjustment for age, body mass index, activity and calories intake (odds ratio [OR] 2.09, 95% confidence interval [CI] 1.39-3.14, P < 0.001)

Discussion: Sarcopenia is associated with resistance, impaired fasting glucose, and diabetes. The loss of muscle mass in older adults with diabetes is thought to be due to multiple factors, including the following possible mechanisms: First, loss of anabolic activity due to increased insulin resistance. Second, loss of anti-inflammatory responses (tumor necrosis factor-α, highly expressed in adipose tissue of insulin-resistant obese patients, induces interleukin-6, thereby inhibiting muscle tissue differentiation) leads to sarcopenia. This loss is also attributed to changes in muscle fiber composition (a decrease in aerobic type 1 fibers and an increase in glycolytic type 2 fibers) and mitochondrial dysfunction associated with muscle aging. Conversely, sarcopenia acts as a risk factor for diabetes.

Conclusion: Diabetes mellitus is a predictor for accelerated muscle mass loss in middle-aged and older men.

Soyoung KIM, Minseon PARK

Seoul National University Hospital, Seoul, Corée (République de)

Context: As population aging accelerates, healthcare expenditures are steadily increasing. In Korea, poor diet quality has been linked to various chronic diseases, but evidence on its association with actual medical costs remains limited.

Objectives: This cross-sectional study examined the association between diet quality, measured by the Korean Healthy Eating Index (KHEI), and med-ical expenditures among Korean adults.

Methods: We used data from the Korea National Health and Nutrition Examination Survey (2016–2021). Adults aged ≥20 years with complete data on diet, sociodemographics, and healthcare use were included. Medical costs were estimated from self-reported service use and converted to USD. KHEI scores were categorized into quartiles. Multivariable linear regression was used to assess the association between KHEI quartiles and log-transformed costs. Subgroup analyses were conducted by age (<57 vs. ≥57 years), and sensitivity analyses treated KHEI as a contin-uous variable. A two-part model addressed skewed, zero-inflated cost data.

Results: Compared to Q1, participants in Q4 had significantly lower inpatient (β = -0.080; 95% CI: -0.139 to -0.020) and total costs (β = -0.086; 95% CI: -0.144 to -0.027). In the younger group, Q4 was associated with lower total costs (β = -0.115; 95% CI: -0.198 to -0.031). Higher continuous KHEI scores were also linked to lower costs. In the two-part model, Q4 participants had a higher probability of incurring any cost but lower conditional costs (Q3 vs. Q1: β = -0.173; Q4 vs. Q1: β = -0.160; both p < 0.05).

Discussion: Higher adherence to a healthy dietary pattern, measured by the Korean Healthy Eating Index (KHEI), was associated with lower inpatient and total healthcare expenditures after adjusting for sociodemographic and health factors. Although participants with higher KHEI scores were older and had more chronic conditions, they incurred lower medical costs, possibly due to better disease management. The inverse association was significant mainly among younger adults, suggesting age-specific differences in how diet affects healthcare use.

Conclusion: Higher diet quality was associated with reduced healthcare costs in Korean adults, especially among younger individuals. Promoting healthy eating may help lower economic burdens in aging soci-eties.

Context: Triglyceride–Glucose Index, a simple proxy of Metabolic Syndrome

Objectives: The triglyceride–glucose (TyG) index has recently been proposed as a surrogate marker of metabolic syndrome risk, but its association with individual metabolic risk components has not been clearly established. This study aimed to investigate the relationship between the TyG index and various metabolic risk variables in a representative sample of the Korean general population.

Methods: We analyzed data from 6,614 participants (mean age, 46.7 ± 22.5 years; mean BMI, 23.3 ± 4.2 kg/m²; 54.3% female) from the 2021 Korea National Health and Nutrition Examination Survey (KNHANES). Sociodemographic data (height, weight, neck circumference) and cardiometabolic parameters (waist circumference, blood pressure, fasting plasma glucose, total cholesterol, HDL cholesterol, triglycerides, and fasting insulin) were collected. Pearson's correlation analyses were performed using SPSS for Windows (version 18.0; IL, USA). Two-sided p values < 0.05 were considered statistically significant.

Results: The TyG index showed a strong positive correlation with the HOMA-IR index, glycated hemoglobin (HbA1c), and white blood cell count after adjustment for age, sex, BMI, waist circumference, blood pressure, total cholesterol, and HDL cholesterol ($p < 0.001$).

Discussion: . Further controlled clinical studies are warranted to confirm these findings and clarify the underlying mechanisms.

Conclusion: The triglyceride–glucose index may serve as a significant and practical marker of metabolic syndrome in the general population.

ID 395- Usefulness of critical flicker fusion threshold (CFFT) as a measurement tool of fatigue symptom in primary care

Shehroz AHMED, Helen DOYLE, Charles DINGA, Pauline ALBYRNE

Drdoyle'ssurgery,shanacloon,duncannon, Wexfor, Irlande

Context: Patients on antiplatelet medication, such as Aspirin and Clopidogrel, are at increased risk of gastrointestinal complications. PPIs are frequently co-prescribed for gastroprotection, but certain PPIs (e.g., Omeprazole) can negatively interact with Clopidogrel due to shared metabolic pathways (CYP2C19). This audit was undertaken in a rural Irish GP practice to evaluate prescribing practices and ensure safety in a population with increasing multimorbidity and polypharmacy.

Objectives: To assess the extent of PPI co-prescription in patients taking antiplatelet therapy. To determine whether the choice of PPI aligns with recommended guidelines, particularly for patients on Clopidogrel.

Methods: A retrospective chart review of patients aged >16 years prescribed antiplatelet therapy was performed. Data collected included PPI co-prescription status and appropriateness of PPI choice. Audit standards

were based on JACC recommendations, and data were analysed using Excel.

Results: Total patients on Aspirin: 38 PPI co-prescribed: 22 (57.9%) No PPI documented: 16 (42.1%) PPIs used: Esomeprazole (8), Pantoprazole (7), Lansoprazole (6), Omeprazole (1) 2 patients were on Clopidogrel: 1 prescribed Pantoprazole (appropriate) 1 prescribed Omeprazole (interaction risk identified)

Discussion: This audit shows inconsistent adherence to gastroprotection recommendations for patients on antiplatelet therapy, with over 40% having no documented PPI cover. This may reflect incomplete documentation, OTC PPI use, or missed prescribing opportunities. One case of inappropriate PPI selection in a patient on Clopidogrel highlights the need for improved awareness of drug–drug interactions, particularly the avoidance of Omeprazole due to CYP2C19 inhibition. Strengthening medication reviews, especially within CDM clinics, and improving documentation practices will help reduce gastrointestinal risk and optimise patient safety.

Conclusion: There is inconsistent PPI co-prescribing in patients taking antiplatelet therapy, with a notable proportion lacking gastroprotective cover. An inappropriate PPI choice was identified in a patient on Clopidogrel. Improvements are needed in prescription review, documentation, and guideline-based selection of PPIs (preferably Pantoprazole when Clopidogrel is used) to enhance patient safety and reduce adverse outcomes

ID 2175- Uses of Information and Communication Technologies by patients: typology, perceptions and determinants

Théo DUGUET

Sorbonne University, Paris, France

Context: Childhood overweight and obesity are public health concerns, with rising prevalence observed across many countries. Several factors are linked to this trend, including exposure to antibiotics. While recent studies suggest a potential link, few data exist for children older than two years old, and none have been conducted in the French population.

Objectives: Investigating the association between antibiotic prescriptions during general practitioner consultations and the onset of overweight or obesity among French children aged 2–17 years.

Methods: A retrospective cohort study was conducted using data from the French primary care database XXXX (2012–2022). Children aged 2–17 with an initial BMI classified as normal were included. Antibiotic exposure was assessed both as the average annual number of prescriptions received and as the absolute number of prescriptions. The main outcome was the onset of overweight or obesity (IOTF criteria). Relative risks (RRs) were estimated using quasi-Poisson regression models, adjusted for sex, age, and medical centres.

Results: Among 8,353 included children (47,054 person-years), 1,026 developed overweight or obesity. A significant dose–response relationship was identified in the trend analysis between the mean annual number of antibiotic prescriptions and the onset of overweight or obesity (RR = 1.20; 95% CI: 1.11–1.29; $p < 0.001$), indicating a 20% higher risk for each additional antibiotic prescription per year. When considering the absolute number of antibiotic prescriptions between ages 2 and 4, a significant association was also observed (RR = 1.09; 95% CI: 1.03–1.14; $p < 0.001$). Both high and non-high ecological impact antibiotics were implicated.

Discussion: Although antibiotics are often essential in paediatric care, this study from a real-word database found a significant dose–response association between antibiotic exposure and the development of overweight or obesity in children aged 2-17 years. These results align with previous epidemiological studies, biological plausibility, and veterinary evidences of antibiotics used as growth promoters. It represents the first evidence from French primary care.

Conclusion: These findings strengthen concerns that antibiotic exposure may

contribute to overweight and obesity during childhood. They support the need for strengthened antibiotic stewardship in primary care and further evaluation of modifiable risk factors for overweight and obesity.

Satis Waran Nair KRISHNAN

Dr, Drogheda, Irlande

Context: General practitioners face growing administrative workloads, with clinical documentation contributing significantly to stress and burnout. This practice-based reflection describes the supervised introduction of an artificial-intelligence (AI) language model (ChatGPT) into routine documentation at a single Irish general practice. The initiative aligns with WONCA's values of liberty, equity, fraternity, and humanism by exploring responsible innovation that supports clinician well-being and enhances patient safety.

Methods: Over three months, ChatGPT (GPT-5) was used to generate structured SOAP-style consultation notes, referral letters, and patient-education summaries under clinician supervision. Baseline manual documentation metrics were compared with those recorded after implementation. Outcomes assessed included average documentation time, completeness of safety-netting statements, and note readability. Qualitative feedback was gathered from GPs regarding usability, confidence, and perceived impact on patient interaction.

Originality: To our knowledge, this is one of the first documented primary-care reflections on real-world AI integration in clinical documentation. The approach illustrates how digital tools can be ethically and safely embedded into existing workflows while maintaining clinician oversight and confidentiality compliance.

Lessons learned and future implications: AI-assisted documentation reduced average note-completion time by approximately 32 %, improved inclusion of safety-netting statements from 68 % to 96 %, and enhanced record clarity. Staff reported improved focus on patient communication and reduced cognitive fatigue. Lessons learned include the importance of transparent governance, data protection, and balancing empathy with technology.

Discussion: The introduction of supervised AI support demonstrated measurable workflow improvements while maintaining safety and professionalism. Although limited to a single-practice reflection, findings suggest that AI can complement—not replace—human clinical judgment. The experience underscores the need for ethical responsibility, transparency, and patient trust, reinforcing the role of family doctors as innovators who integrate technology while preserving empathy and equity.

Conclusion: Supervised AI assistance can enhance documentation efficiency and patient safety without compromising professional judgment or data integrity. Broader multicentre evaluation is warranted to develop evidence-based frameworks for equitable and human-centred AI adoption in family medicine.

ID 1118- USS Examination Techniques for the assessment of common pathologies of the Shoulder, Knee and Wrist in Family Medicine

Prathamesh KARPE

Hod&associate Professor,gam&rc,shiroda Goa,india, Shiroda, Inde

Context: Context: Ayurveda, the science of life, describes comprehensive methods for maintaining health and managing disease through medicinal, surgical, and parasurgical approaches. Among these, Agnikarma (therapeutic cauterization) and Viddhakarma (controlled micro-needling) are classical interventions indicated in various musculoskeletal, neurological, and pain-related disorders. Their application in modern

integrative pain management has shown encouraging outcomes. Keywords: Ayurveda, Agnikarma, Viddhakarma, Pain Management, Integrative Medicine, Case Reflection,Kshipra marma.

Methods: This reflection is based on three clinical cases. Case 1: A 45-year-old male with bilateral knee osteoarthritis (VAS 7/10) underwent Agnikarma using a heated Suvarna Shalaka (gold probe) on tender points. Pain reduced to 2/10 immediately and to 1/10 after five days. Case 2: A 45-year-old obese female with anosmia, frontal headache, and joint pain received Viddhakarma using a 26G needle at nasal and eyebrow points, followed by Agnikarma on painful joints. Complete relief from headache and joint pain was achieved with partial restoration of smell. Case 3: A 65-year-old female with radiating shoulder pain to right hand,(VAS 8/10) was treated with Viddhakarma on 2 fingers above Kshipra marma and 4fingers above and below flexed right elbow joint,lateral aspect and Agnikarma on the shoulder girdle. Pain reduced to 1/10 post-procedure immediately.

Originality: Originality: These procedures offer rapid, sustained pain relief with negligible adverse effects, serving as non-pharmacological alternatives to opioids and NSAIDs. They integrate traditional dosha-based reasoning with modern procedural safety.

Lessons learned and future implications: Agnikarma and Viddhakarma are effective, minimally invasive, and low-cost methods for acute and chronic pain management. Their inclusion in integrative pain clinics could enhance patient outcomes and reduce drug dependency.

Discussion: The observed cases demonstrate significant pain relief through Agnikarma and Viddhakarma, likely via enhanced circulation and neural modulation. These safe, low-cost techniques offer effective non-pharmacological alternatives to NSAIDs or opioids. Their integration into modern pain clinics may strengthen evidence-based, holistic approaches to global pain management.

Conclusion: The revival of classical Ayurvedic procedures holds promise for global integrative medicine by combining ancient therapeutic wisdom with modern clinical practice.

ID 45- Vaccination Coverage and Associated Factors of Hepatitis B, Measles-Mumps-Rubella, Varicella, and Tetanus-Diphtheria-Acellular Pertussis Among Primary Health Care Workers in Qatar: A Retrospective Study (2020–2024)

Jia Yun LIU, Shu Chuen LAU

Cardinal Tien Hospital, New Taipei City, Taïwan

Context: Insulin resistance and impaired glucose regulation are major contributors to the development of type 2 diabetes mellitus (T2DM). Inositol, a naturally occurring carbocyclic sugar, has shown as a low-risk intervention to improve metabolic outcomes. Although its efficacy in managing polycystic ovary syndrome (PCOS) is well established, its metabolic applications remain unclear.

Objectives: This systematic review aimed to evaluate the effects of inositol supplementation in adults with various metabolic risk factors.

Methods: A systematic search of PubMed was conducted to identify studies published between January 2015 and May 2025 that investigated the effects of myo-inositol or D-chiro-inositol supplementation in adults with metabolic risk factors. Eligible studies were limited to human and English trials with outcomes related to glycemic parameters. Studies exclusively focused on PCOS or lacking relevant metabolic endpoints were excluded. The primary outcome was change in insulin resistance, assessed by the homeostasis model assessment of insulin resistance (HOMA-IR). Secondary outcomes included fasting plasma glucose (FPG), oral glucose tolerance test (OGTT) results, incidence of gestational diabetes mellitus (GDM), and adverse effects. Key study characteristics and metabolic outcomes were extracted and synthesized descriptively.

Results: A total of twelve studies were included. Most trials reported significant

reductions in HOMA-IR following myo-inositol supplementation, either alone or in combination with other agents. Improvements were also observed in glycemic markers such as fasting glucose and OGTT results. Four out of five studies reported significantly lower GDM incidence in intervention groups. No serious adverse events were reported.

Discussion: Inositol supplementation appears to be a safe and effective for improving insulin resistance, as evidenced by consistent reductions in HOMA-IR across diverse at-risk populations. The observed improvements in secondary glycemic outcomes and the low incidence of adverse effects further suggest its potential role as an adjunctive therapy for early metabolic risk management. However, variations in study design and participant characteristics highlight the need for more standardized research protocols.

Conclusion: Current evidence supports inositol supplementation as a promising adjunctive intervention to enhance insulin sensitivity and metabolic outcome. Future studies should determine the optimal dosage, timing, and target populations—particularly among individuals with prediabetes—to facilitate its integration into routine metabolic care.

ID 1145- Vaccine hesitancy

Kwang Yoon KIM

Department Of Family Practice And Community Health, Ajou University School Of Medicine, Suwon, Corée (République de)

Context: This study explored whether measuring extracellular fluid (ECF) changes can serve as a quantitative indicator of treatment effectiveness for chronic venous disease (CVD).

Objectives: The Clinical-Etiology-Anatomy-Pathophysiology (CEAP) classification to describe patients with chronic venous disease (CVD) has limitations in that it cannot be quantitatively evaluated. Thus, we aimed to determine whether measuring changes in extracellular fluid (ECF) can be an objective and quantitative indicator after CVD treatment.

Methods: In this retrospective, single-center study, changes in ECF and symptoms of CVD were analyzed using bioelectrical impedance analysis (BIA) at baseline (V0), after 1 month (V1), and after 3 months (V2) between April and November 2023. Subgroup analysis was performed to determine whether sex, body mass index (BMI), baseline CEAP grade, and additional diuretic use could affect further ECF reduction.

Results: Compared with V0, ECF in both legs significantly reduced over the intervention period. At V1, compared with V0, significant ECF reduction in the right leg (RL) (-0.47%, P = 0.0085) and left leg (LL) (-0.57% and P = 0.0021) were observed. ECF reduction at V2 was more pronounced compared to 1 month after treatment in the RL (-0.66%, P = 0.001) and LL (-0.71% and P = 0.0003). Sex, baseline CEAP grade, and additional diuretic use did not affect the difference in the decline of ECF after treatment, but BMI caused significant differences in the degree of ECF reduction after treatment.

Discussion: Using bioelectrical impedance analysis, we found significant ECF reduction in both legs after 1 and 3 months of treatment. The reduction was more pronounced at 3 months. This suggests ECF measurement could be a reliable method to assess CVD treatment outcomes, with BMI being a key factor in the degree of fluid reduction.

Conclusion: Changes in ECF evaluated by BIA can be an objective indicator of the treatment effect of chronic venous insufficiency. Diuretic combination with a venoactive drug did not bring additional benefits. The decrease in ECF after CVD treatment was more pronounced in patients with BMI less than 23.

(2) Wonkwang University Sanbon Hospital, Wonkwang University School Of Medicine, Gunpo, Corée (République de)

Context: Many studies have evaluated the impact of oral inflammatory diseases on muscle strength in the elderly, but previous studies have been limited to cross-sectional designs. To reveal the causal effects of this relationship, we conducted this prospective study.

Objectives: The aim of our study was to determine the association between oral health and baseline grip strength, and the causal effects of oral health on muscle strength after 4 years in an elderly Korean population using nationally representative data.

Methods: This prospective study used the database from the Korean Longitudinal Study of Ageing (KLoSA). The participants included 6,940 individuals aged 55 years or older. Oral health satisfaction (OHS) was assessed using the General Oral Health Assessment Index (GOHAI), and muscle strength was measured by maximum handgrip strength at baseline and every 2 years during the 4-year follow-up. Multiple confounding factors were evaluated.

Results: This study included 2,936 men (mean OHS score 51.4, mean maximum handgrip strength 31.6 kg) and 4,001 women (mean OHS score 51.2, mean maximum handgrip strength 20.2 kg). Baseline OHS was associated with grip strength in both men (β=1.16, P=0.028) and women (β=1.11, P=0.001). Using a mixed-effects model, we found that changes in OHS over the study period were associated with changes in handgrip strength over time in women (β=0.045, P<0.001), and were marginally associated in men (β=0.02, P=0.059). The sarcopenia group at 4 years was associated with poor baseline OHS status in women (adjusted OR 1.41, 95% CI 1.10-1.96).

Discussion: Low grip strength not only affects physical function but also has a broader impact on various poor health outcomes in the elderly. This study implicates that maintaining and enhancing oral health is important for preserving muscle function in the elderly.

Conclusion: We observed an association between baseline oral health and handgrip strength, and a positive longitudinal influence of oral health on changes in muscle strength in elderly Koreans over 4 years.

Corresponding author: Jungun Lee, tracheo@kdh.or.kr

ID 372- Validation of indications for point-of-care of ultrasound in general practice based on international expert consensus: systematic literature review

Michael COLE

Imperial College London, London, Royaume-Uni

Context: Addressing inequities in health outcomes requires that medical curricula facilitate critical evaluation of the structural determinants of health and the intersectional oppression of marginalised groups. To support Primary Care Placement Leads in enhancing their curricula, I applied a health justice lens - a structured evaluative framework designed to promote equity-focused education. This work is sustainable as it aligned with continuing initiatives, including curriculum 'deep dive' processes, assessment question-writing days, and faculty development activities, and informs ongoing strategy.

Methods: The health justice lens assessed materials across three intersecting EDI themes: representation, humility, and advocacy. Representation analysed the diversity of people depicted in case studies and materials, assessing whether they reflect local populations, redress under-representation, and subvert stereotypes. Humility focused on person-centredness, accessibility, and decolonising within content, outcomes, and assessments. Advocacy explored how learners apply knowledge to challenge health injustices in primary care. The process followed a structured EDI mapping approach: meetings with placement leads; review of existing mapping; systematic resource review using the health justice lens; collaborative discussions; feedback to management; implementation of adjustments; and presentation of findings and future considerations. Strengths included strong engagement and reflective dialogue; limitations included time and curriculum space.

Originality: This approach operationalises EDI review through a health justice framing that integrates representation, humility, and advocacy across curriculum, assessment, and faculty development. It differs from existing audits by embedding health justice and decolonising principles into curriculum design processes in a context-specific, iterative and sustainable manner.

Lessons learned and future implications: The experience highlighted the value of iterative collaboration and reflective discussion in embedding EDI principles. Findings now inform curriculum deep dives, assessment question-writing, and faculty development, supporting sustainable, health justice-oriented educational practice.Specific examples of changes included the innovative 'Stop and Think' bias resource.

Discussion: The mapping process was deeply interpersonal and reflective, relying on open communication to navigate faculty members' diverse lived experiences and positionalities. Establishing trust and shared understanding was essential when introducing new health justice perspectives within an already content-dense curriculum, highlighting the need for dialogue-led, empathetic curriculum change.

Conclusion: Using a health justice lens provides a transferable, systematic method to align primary care education with broader institutional equity goals, advancing healthcare training.

ID 758- Validity and Prevalence of Pediatric Feeding Disorders in a General Population Sample Using the MCH-FS

Eva KICKHOEFEN, Chiara THOMAS, Katrin DÖRR, Riho ATSUMI, Viet Duc BUI, Vitalii MININ, Andy MAUN

Institut Für Allgemeinmedizin, Freiburg Im Breisgau, Allemagne

Context: People from marginalized groups continue to face structural inequities in healthcare (e.g. longer waiting times, higher rates of misdiagnosis, feeling dismissed in clinical encounters). These inequities not only affect individual health outcomes but also contribute to higher overall healthcare costs through delayed diagnoses, inadequate treatments, and increased use of emergency services. Promoting diversity-sensitive and respectful communication among medical students and healthcare professionals early in their education is key to building equitable and inclusive care.

Objectives: By the end of the session, participants will be able to: 1. Recognize and reflect on key diversity dimensions such as culture, migration, disability and LGBTQIA+ identities. 2. Identify and question their own stereotypes and unconscious biases. 3. Explain why diversity-sensitive communication is essential for equitable, high-quality care. 4. Apply inclusive communication strategies and use practical tools and resources for working with diverse patient groups in primary care.

Teaching method and workshop: The workshop combines brief theoretical input, self-reflection exercises, and small-group activities to foster applied learning, practical skill development, and peer exchange. Participants engage in case-based discussions and collaborative problem-solvin

Expected outcomes: Participants will gain a deeper understanding of diversity and inclusion in healthcare, acquire practical strategies and resources to promote equitable, patient-centered communication, and benefit from peer discussion and networking opportunities.

Conclusion: We are all influenced by unconscious biases. Reflecting on them and practicing inclusive communication enables healthcare professionals to promote equity in care and contribute to a more inclusive society.

ID 2279- Verbal consent as a key care enhancer in nursing homes medical care: an uncontrolled before-after study

Seungmin OH

Seoul Medical Center, Seoul, Corée (République de)

Context: With advances in medical technology and early detection, the survival rate of cancer patients has increased significantly. However, as the number of elderly cancer survivors grows, concerns regarding their post-treatment quality of life (QoL) have become more critical.

Objectives: The purpose of this study is to identify the factors that affect the quality of life of elderly cancer survivors and to establish the basis of support programs in primary health care to help elderly cancer survivors return to their stable and high-quality daily lives.

Methods: Raw data of the National Health and Nutrition Examination Survey(2016-2020) were used. Retrospective data searching was performed and a sample of 513 cancer survivors aged 60 years or older was included. The median age is about 65.8 years. The data were analyzed by descriptive statistics, t-tests, ANOVA, Pearson correlation, and multiple regression analysis.

Results: The most significant factors affecting the quality of life of elderly cancer survivors were activity limitation(β=.32, p<.001), subjective health status(β =-.21, p<.001), age(β=-.14, p<.001), economic status(β=.14, p=.003) and gender(β=-.06, p<.001).

Discussion: Physical independence is a major determinant of well-being among older cancer survivors. Self-perception of health beyond clinical test results also plays a vital role in perceived life satisfaction. Overall, the findings underscore the multifactorial nature of QoL, requiring a holistic, interdisciplinary approach that integrates physical rehabilitation, mental health counseling, and socioeconomic assistance.

Conclusion: Quality of life in elderly cancer survivors is influenced by multiple, interrelated factors—particularly physical activity limitation, perceived health status, age, economic condition, and gender. To enhance QoL, primary health care systems should prioritize personalized, community-based interventions that promote physical function, improve subjective health perception, and provide socioeconomic and emotional support. Strengthening multidisciplinary collaboration among healthcare professionals, social workers, and community organizations will be essential in helping elderly cancer survivors maintain independence and achieve stable, meaningful lives after treatment.

(4) Centre Hospitalier Gustave Dron, Department Of Infectious Diseases, Service Universitaire Des Maladies Infectieuses, 59210, Tourcoing, France, Tourcoing, France

Context: For people living with human immunodeficiency virus (PLWHIV), the advent of antiretroviral therapy has significantly improved both prognosis and quality of life. HIV infection is now considered a chronic disease. As patients age and comorbidities increase, the general practitioners (GPs)'s central role remains insufficiently described.

Objectives: To analyse the perceptions of GPs in the Hauts-de-France region in 2025 who have at least one PLWHIV among their patients, focusing on their views regarding the specificities and their position in their overall management of these patients.

Methods: A quantitative, descriptive, cross-sectional study was conducted using on a questionnaire sent to GPs practising in the Hauts-de-France region who are registered as the primary care physician for at least one PLWHIV. Qualitative variables were compared using Chi-square or Fisher tests, quantitative ones with Student or Mann–Whitney tests (Shapiro–Wilk for normality); significance was set at $p \leq 0.05$.

Results: Among the 773 practitioners contacted, 71 were included. GPs were most comfortable in vaccination (median 6/10 [IQR:

5-8]) and least comfortable in the management of iatrogenic risks (median 4/10 [IQR: 2-5]). Sixty-two percent routinely asked their patients about self-medication, and 95% checked for potential drug interactions when prescribing a new treatment. Nonetheless, vigilance regarding high-risk molecules (such as divalent cations and proton pump inhibitors) remained inadequate. Most GPs believed they played an essential role in overall care, particularly in reporting “affection de longue durée” (97%) and monitoring vaccinations (93%), with varying levels of compliance depending on the recommendations (75% reported pneumococcal vaccination, 29% hepatitis A vaccination). Some cancer screenings were well followed (e.g. no specific guidelines for prostate or breast cancer), while others, such as adaptation for anal margin screening were less applied (56%).

Discussion: GPs expressed a willingness to be involved in the follow-up of PLWHIV, despite moderate self-assessed confidence. Their practices are generally in line with recommendations, particularly regarding vaccinations, but attention to drug interactions and certain specific screenings remains suboptimal. Nearly half would like additional training. Strengthening coordination with specialists appears crucial.

Conclusion: GPs lack confidence in managing PLWHIV but express a genuine desire to be involved in patient care.

ID 1738- Violence Motivated by Gender, Racism, and Xenophobia in São Paulo, Brazil: Implications for Medical Education

Emine Merve ERSEVER

Ankara University, Ankara, Türkiye

Context: Objectives: The current investigation sought to evaluate the impact of a 24-week squat exercise regimen on body composition and muscle oxygenation among overweight and obese older adults, with particular emphasis on outcomes related to sarcopenia.

Methods: A prospective case series involved overweight and obese older adults performing body-weight squats three times a week for 24 weeks. Body composition measures, including skeletal muscle index (SMI), fat mass, and limb lean mass, were taken via dual-energy X-ray absorptiometry (DXA) at baseline and after the intervention. Muscle oxygen saturation (SmO_2) was also measured using an optical sensor on the dominant leg, focusing on the vastus lateralis (VL) and biceps femoris (BF). Descriptive analyses reported changes as median or mean ± standard deviation values.

Originality: This study offers a novel perspective on community-based exercise interventions for obese older adults living in geographically disadvantaged areas, a group rarely represented in rehabilitation research. Combining body composition analysis with non-invasive muscle oxygenation monitoring it introduces an accessible approach to evaluate physiological changes outside clinical settings.

Lessons learned and future implications: Implementing such interventions through collaboration between primary care teams and community physiotherapists could help reduce health inequalities and promote active aging. Future studies should include larger samples and long-term follow-up to validate these outcomes and guide the integration of practical exercise models into public health frameworks

Discussion: Nine participants (6 males, 3 females; mean age 68.2 ± 3.9 years; mean BMI 32.3 ± 4.9 kg/m²) completed the intervention. From baseline to post-exercise, median changes were observed in BMI (−0.88 kg/m²), body weight (−2.0 kg), fat mass (−1.5 kg), and SMI (+0.04 kg/m²). Muscle oxygenation improved in both VL and BF muscles, with a median increase in SmO_2 of +0.8%

Conclusion: Twenty-four weeks of regular squat exercise was associated with reductions in body fat and improved local muscle oxygenation among inactive obese older adults. These findings suggest that simple, home-based resistance exercises can enhance metabolic efficiency and functional health in elderly populations with limited access to structured rehabilitation or exercise programs

Corresponding author: Emine Merve Ersever, merversever@gmail.com

ID 1735- Virtual Care as Deployed to Improve Access to Primary Care in 3 Canadian Provinces: A policy focused qualitative study

Sang Yeoup LEE, Ye Li LEE

Pusan National University Yangsan Hospital, Yangsan, Corée (République de)

Context: Functional constipation affects 10–12% of the global population, significantly impairing quality of life. Current treatments are often insufficient, creating a need for safe, effective long-term strategies. Probiotics are promising, particularly spore-forming Bacillus coagulans. While the B. coagulans MTCC 5856 (LactoSpore®) strain has shown efficacy in diarrhea-predominant irritable bowel syndrome, its effectiveness in managing functional constipation is clinically unverified.

Objectives: The primary objective of this study was to evaluate the efficacy and safety of B. coagulans MTCC 5856 supplementation on clinical symptoms and the fecal microbiome in adults with functional constipation.

Methods: This 8-week, randomized, double-blind, placebo-controlled trial enrolled 80 adults (aged 19–75) with functional constipation, as defined by the Rome IV criteria. Participants were randomly assigned (1:1) to receive B. coagulans MTCC 5856 (2×10^9 CFU/day) or placebo. The primary endpoint was the change from baseline in the constipation Visual Analogue Scale (VAS) score at weeks 4 and 8. Secondary endpoints included IBS Quality of Life (IBS-QOL), IBS Symptom Severity Score (IBS-SSS), and gut microbiome composition. An intention-to-treat (ITT) analysis was performed using linear mixed-effects models.

Results: In the ITT analysis (n=80), the B. coagulans group showed significantly greater improvement in constipation VAS scores versus placebo at week 8 (adjusted mean difference: 28.8; 95% CI, 14.1–43.4; $p < 0.001$) and week 4 ($p = 0.012$). At week 8, significant improvements were also seen in VAS-IBS ($p < 0.001$), IBS-QOL ($p = 0.033$), and IBS-SSS ($p = 0.019$). However, no significant differences in fecal microbiome composition or diversity were found between the groups. No intervention-related adverse events were reported.

Discussion: This study is the first RDBPC to demonstrate that B. coagulans MTCC 5856 significantly improves symptoms in adults with functional constipation. The fact that this strain also shows benefit in IBS-D suggests a potential bidirectional regulatory effect on gut motility. Symptomatic improvement occurred without significant alterations to the overall microbial composition, suggesting that the mechanism of action may be functional (e.g., metabolic) rather than structural.

Conclusion: Eight-week supplementation with B. coagulans MTCC 5856 was effective in improving clinical symptoms and quality of life in adults with functional constipation and demonstrated an excellent safety profile.

(3) Monash University, Melbourne, Australie

Context: Counselling women about osteoporosis prevention in primary care is typically performed in post-menopausal women as part of a ‘healthy checkup’ or following low trauma fracture diagnosing osteoporosis. However, implementing lifestyle change earlier can influence rates of osteoporosis after menopause. Patient perspectives are relevant in considering approaches to counselling perimenopausal women to improve compliance and thus overall bone health.

Objectives: This session aims to present perspectives on the methods and timing of osteoporosis prevention advice given to

women in perimenopause, based on our experience in xxx general practice, by considering guideline recommendations and what patient and practitioner barriers to implementation exist. Reference to international guidelines will be included to support reflection for primary care physicians across continents.

Teaching method and workshop: This session is designed to encourage self-reflection on possible change to practice and will be presented using mixed methods that incorporate: 1. Presentation of information on preventative advice from various guidelines that are useful to the family ph

Expected outcomes: Learning outcomes include: 1. Review the recommendations on lifestyle advice to prevent osteoporosis in perimenopausal women. 2. Understand patient perspectives and family practitioner barriers to implementation when counselling perimenopausal women on os

Conclusion: In recognition of the barriers to counselling women about osteoporosis prevention earlier than the first fracture, this session is offers practical suggestions that incorporate evidence based knowledge and guidelines to empower the primary care clinician to provide up to date advice for women in perimenopause. Consideration of the role of menopause hormonal therapy, lifestyle measures and screening activities will be reviewed to support improvements in women's preventative health activities.

ID 2266- Visceral Leishmaniasis - Human Immunodeficiency Virus Coinfection and Mortality in XXX, XXX(2015–2024): Epidemiological Characterization and Intervention Strategies

Michal SHANI, Limor ADLER, Shlomo VINKER, Yochai SCHONMANN, Galia ZACAY, Ilan YEHOSHUA, Robert HOFFMAN, Jossef AZURI, Haymann ANTHONY

Tel Aviv University, Tel Aviv, Israël

Context: Primary care faces numerous challenges, including an aging population, physician shortages, evolving roles of medical staff, increasing bureaucracy, and the growing impact of telemedicine and artificial intelligence. These changes raise critical questions about the future role of family physicians.

Objectives: To evaluate the perceptions of family physicians about the future of family medicine.

Methods: We conducted focus group discussions using a semi-structured interview developed by the TLV-GPRN (Tel Aviv General Practitioner Research Network). Discussions explored key themes related to the future of family medicine. The meetings were transcribed and analyzed using a thematic analysis approach.

Results: Three focus groups were conducted: two with young family physicians and one with senior family medicine leaders. A total of 18 practicing family medicine specialists participated. The interviews were held via Zoom between October and December 2024. Family physicians expressed confidence in their ability to adapt to future challenges while maintaining comprehensive patient care. They emphasized the importance of adopting new technologies to enhance diagnosis, patient management, and efficiency while minimizing administrative burdens. A key concern was balancing their broad expertise with increasing topic specific specialization demands. Participants highlighted the need for structured support to integrate AI and digital tools into daily practice while preserving the physician-patient relationship.

Discussion: Family physicians feel prepared to evolve with the healthcare landscape but emphasize the need for strategic technology implementation and role adaptation.

Conclusion: Policymakers should incorporate their perspectives when designing future healthcare systems to ensure that changes align with primary care needs and patient-centered care principles.

ID 796- visual hallucinations in a blind patient

Diana Marinha CRUZ, José M. SEARA, Daniel GONÇALVES

Ulsam, Viana Do Castelo, Portugal

Context: This is a clinical case of a 71-year-old woman who went to an urgent consultation for pain in the distal region of the sole of the right foot; she denied trauma or effort. On physical examination, there was an induration, which was painful on palpation.

Methods: Ultrasound and X-ray evaluation showed a foreign body (FB) associated with a granuloma in the distal end of the metallic linear image, measuring 6.5 cm, projected at the base of the second metatarsal. Sent to traumatology, a partial extraction of the FB was performed. It showed extensive corrosion, causing a metallosis reaction. The patient kept a part of the FB with about 3 cm, with adequate healing, and she recovered completely.

Originality: When asked about the discovery, she remembered an episode of trauma with a rod from an umbrella, more than 40 years ago, which was supposedly removed by a healer. She was unaware that that piece of the object remained.

Lessons learned and future implications: This is a rare case of a 71-year-old woman with a metallic FB retained in the foot for an extended period after the trauma, without symptoms. Despite surgical removal, a residual fragment remained; nevertheless, the patient achieved full recovery without apparent complications. Although a fragment of an FB remained on her foot, this did not prevent the patient from fully recovering and continuing to walk, without complaints, during two years of follow-up. However, it is unpredictable if any other symptoms may develop in the future.

Discussion: This case highlights the importance of thorough clinical history-taking and consideration of remote traumatic events in the differential diagnosis of unexplained pain in the foot or other anatomical regions in elderly patients. However, unusual FBs can also appear in other age groups, particularly in patients of other nationalities, which is increasingly common with the emigration of patients whose countries have very different social, cultural, and health conditions.

Conclusion: This case underscores the extraordinary capacity of the human body to tolerate retained foreign materials for prolonged periods. Clinicians should maintain some suspicion for FBs in patients presenting with atypical localized pain, even when the inciting event may have occurred decades earlier.

ID 2059- Vitamin D Levels and Prophylactic Supplementation in Adults Aged 80 Years and Older: Frailty-Oriented Implications for Primary Care Practice

Carmen DE SANTIAGO, Paolo Augusto ROMERO MERINO, Rosa Maria GONZALEZ LOPEZ, Carlos Eduardo GOMES RODRIGUEZ

Portillo, Valladolid, Espagne

Context: Hydatidosis is a parasitic zoonosis caused by Echinococcus granulosus, still prevalent in rural areas where livestock and domestic animals coexist. Although hepatic involvement is most common, secondary pulmonary dissemination is unusual and can mimic malignancy. Early recognition in primary care is essential to prevent complications and unnecessary interventions. We present the case of a woman with a history of hepatic hydatidosis who developed multiple pulmonary lesions, initially suspected to be metastatic cancer, and who was followed for several years in coordination between primary care, internal medicine, and thoracic surgery.

Methods: A 67-year-old woman, resident in a rural area and with occupational exposure in a butcher shop, consulted for chronic cough and progressive dyspnea. Chest X-ray revealed multiple nodular opacities in both lungs. CT scan showed multiple cystic lesions compatible with hydatid cysts in hepatic segments IV–VIII and numerous pulmonary nodules of varying size. Serology was positive for Echinococcus granulosus. The patient was treated with albendazole (Eskazole® 400 mg/12 h) under regular clinical and analytical monitoring. Given

the diffuse pulmonary dissemination and absence of surgical indication, a conservative approach was adopted.

Originality: This case illustrates an uncommon presentation of metastatic hepatopulmonary hydatidosis years after surgical treatment of hepatic cysts. The pulmonary spread simulated neoplastic metastases on imaging, representing a diagnostic challenge. Its follow-up within the framework of primary care coordination underscores the relevance of family physicians in the long-term management of chronic parasitic diseases.

Lessons learned and future implications: Primary care has a pivotal role in early suspicion, coordination with specialized care, and sustained follow-up in chronic infectious diseases. Health education and prevention—particularly in rural populations with livestock exposure—remain key strategies.

Discussion: Hydatidosis remains a neglected zoonosis in developed countries, often underdiagnosed. Differential diagnosis with malignant lung disease is complex, especially when lesions are multiple and bilateral. Medical treatment with albendazole can stabilize or reduce cystic lesions, although complete eradication is rare in disseminated forms. Continuous monitoring in primary care, ensuring adherence and managing comorbidities, is fundamental.

Conclusion: Metastatic hepatopulmonary hydatidosis is a rare but important differential diagnosis of multiple lung lesions. This case highlights the value of an integrated, multidisciplinary, and long-term follow-up approach led by primary care.

ID 235- Vitamin D supplementation during winter: a cross-sectional survey in a family medicine practice

Carmen DE SANTIAGO, Paolo Augusto ROMERO MERINO, Rosa Maria GONZALEZ LOPEZ, Ayeiza Maria FELIPE LEMES

Portillo, Valladolid, Espagne

Context: Post-traumatic epilepsy (PTE) is a well-known delayed complication of traumatic brain injury (TBI). In primary care, recognition can be challenging when seizures present only as sensory phenomena, such as olfactory auras, rather than convulsive episodes. These subtle manifestations may lead to underdiagnosis and delayed treatment, affecting patients' quality of life and functional outcomes.

Methods: We describe the clinical follow-up of a young adult male with a history of moderate TBI involving multiple intracranial haemorrhages and diffuse axonal injury type II. He later developed a generalized tonic–clonic seizure preceded by a persistent olfactory aura described as a "smell of gasoline." Neurological examination, brain MRI, EEG, and response to antiepileptic therapy were evaluated.

Originality: Olfactory auras are rare in post-traumatic epilepsy and often overlooked in general practice. This case uniquely correlates mesial temporal structural changes with clinical presentation, emphasizing MRI as a crucial diagnostic tool even when EEG appears normal.

Lessons learned and future implications: Subtle sensory auras can be the first manifestation of structural post-traumatic epilepsy. MRI should be prioritized in atypical or non-convulsive cases regardless of EEG findings. Family physicians must remain vigilant for non-classical seizure forms to prevent diagnostic delays and optimize neurological outcomes.

Discussion: MRI revealed left hippocampal atrophy with subtle T2-FLAIR hyperintensity compatible with early mesial temporal sclerosis, while EEG remained normal. Levetiracetam controlled convulsive seizures but not olfactory auras. Switching to lacosamide initially caused irritability, prompting temporary withdrawal, after which a new seizure occurred temporally associated with cannabis use. Gradual reintroduction of lacosamide (150 mg twice daily) achieved full seizure control. This case highlights the importance of correlating MRI findings with clinical features, especially when EEG results are inconclusive.

Conclusion: In patients with delayed-onset epilepsy following TBI, olfactory auras may represent focal temporal seizures. MRI-based assessment can guide targeted therapy and improve outcomes. Primary care physicians play a key role in recognizing atypical seizure patterns and coordinating timely referral for neuroimaging and specialist evaluation.

ID 22- Vizz, Blujepa, Imaavy, Mounjaro … Exploring the namescape of novel drugs approved by the FDA between 2021 and 2025

Niva KALLUS, Maya LIBSTER

Bar-Ilan University, Azrieli Faculty Of Medicine, Sefad, Israël

Context: This case report describes a 34-year-old man with a history of adult-onset PFAPA (Periodic Fever, Aphthous Stomatitis, Pharyngitis, Adenitis), von Willebrand disease and Factor XI deficiency who experienced an anaphalactic allergic reaction to Hexakapron.

Methods: Case report

Originality: Original and rare

Lessons learned and future implications: The rarity of such reactions presents a diagnostic challenge, as there are no widely accepted, specific tests for TXA-induced allergies. Treatment of these patients in case of bleeding from any cause raises a therapeutic dilemma, to date the most common and widely used anti hemorrhagic medication remains TXA. In this patient it is worth to consider whether the co-morbidity of adult-onset PFAPA, a rare rheumatologic presentation

Discussion: Hexakapron (tranexamic acid - TXA) is a widely used antifibrinolytic agent that is generally well-tolerated, with allergic reactions being uncommon. Severe hypersensitivity responses, such as anaphylaxis, are exceedingly rare, making the occurrence in this case particularly noteworthy. The rarity of such reactions presents a diagnostic challenge, as there are no widely accepted, specific tests for TXA-induced allergies. Skin testing may help confirm the diagnosis, although its sensitivity and specificity are not well-established, and drug provocation tests may sometimes be required to confirm the connection between the drug and the allergic reaction but carries a risk of invoking a life threatening event. Treatment of these patients in case of bleeding from any cause raises a therapeutic dilemma, to date the most common and widely used anti hemorrhagic medication remains TXA. As the response is not dose dependent and can manifest with even nominal exposure, as in this patient during allergy testing, it remains a challenge to manage bleeding.

Conclusion: This case highlights a challenge and treatment dilemma in this patient and others like him who on the one hand have a bleeding disorder and are prone to bleeding, but are severely allergic to Hexacpron on the other hand limiting the available treatment course in case of bleeding from any cause. In conclusion, while the incidence of allergic reactions to Hexakapron remains low, continued awareness, research, and case reporting are critical for advancing our understanding and ensuring patient safety.

ID 302- Vonoprazan versus PPIs in Acute Peptic Ulcer Disease

Zaineb FOURATI

Centre De Soins De Base De Sidi Mansour-Sfax-Tunisie, Sfax, Tunisie

Context: Le cancer du sein est la première cause de mortalité par cancer chez la femme en Tunisie. L'identification des facteurs de risque permet d'adapter les recommandations de dépistage et d'orienter celles à haut risque vers un suivi spécialisé. Cette étude vise à analyser la prévalence des facteurs de risque du cancer du sein dans une population consultant dans un centre de soins primaires.

Objectives: Analyser la prévalence des facteurs de risque du cancer du sein dans une population consultant dans un centre de soins primaires.

Methods: Notre étude est de type descriptif transversale. Elle a été menée auprès d'une population cible composée de femmes âgées de 20 ans et plus, consultant au dispensaire de Sidi Mansour à Sfax lors d'une journée de dépistage organisée le 28 octobre 2024. Les données ont été recueillies à l'aide d'une fiche de renseignement détaillée. Pour l'analyse des données, les participantes ont été classées selon leur niveau de risque de cancer du sein (faible, moyen, élevé) à l'aide du modèle de Gail (Breast Cancer Risk Assessment Tool).

Results: Un total de 40 participantes (n=40) a été inclus dans l'étude. La répartition des niveaux de risque de cancer du sein a révélé que 22,5 % des femmes présentaient un risque faible, 62,5 % un risque moyen et 15 % un risque élevé. Les facteurs de risque les plus fréquents étaient l'absence d'allaitement maternel (42 %), suivi de la ménopause tardive (survenant après 55 ans, 12,5 %), des antécédents familiaux de cancer du sein (25 %) et de l'obésité (7,5 %).

Discussion: La majorité des participantes présentent un risque moyen ou élevé selon le modèle de Gail, ce qui souligne l'importance d'un dépistage renforcé. Les facteurs modifiables identifiés, tels que l'obésité et l'absence d'allaitement maternel, représentent des cibles prioritaires pour les interventions préventives. Les antécédents familiaux et la ménopause tardive confirment l'importance d'une évaluation personnalisée pour identifier les femmes à haut risque

Conclusion: L'évaluation des facteurs de risque est essentielle pour identifier les femmes nécessitant un dépistage renforcé. Les résultats de cette étude permettront d'adapter les stratégies de prévention et de dépistage en soins primaires pour optimiser la prise en charge .

ID 1510- What can we eat for our health within planetary boundaries? An information sheet.

Zaineb FOURATI

Centre De Soins De Base De Sidi Mansour-Sfax-Tunisie, Sfax, Tunisie

Context: Le dépistage précoce du cancer du sein est un pilier essentiel de la réduction de la mortalité liée à cette maladie. Cependant, la participation aux programmes de dépistage reste insuffisante dans de nombreuses régions, en raison de barrières psychosociales, culturelles et économiques.

Objectives: Explorer les facteurs motivants et les barrières perçues par les femmes concernant le dépistage du cancer du sein.

Methods: Type d'étude : Étude descriptive transversale. Population cible : Femmes âgées de 30 ans et plus consultant au dispensaire de Sidi Mansour lors d'une journée de dépistage organisée le 28 octobre 2024. Collecte des données : Utilisation d'une fiche de renseignement structurée recueillant des informations sur les motivations et les obstacles liés au dépistage.

Results: *Nombre total de participantes : 40 femmes (n=40). *L'âge moyen : 51,92± 14,73 ans. *Participation antérieure à une campagne de dépistage : 6 % seulement. *Toutes les participantes (100 %) ont jugé le dépistage comme une méthode efficace pour la détection précoce du cancer du sein. *Une appréhension concernant les résultats a été exprimée par 78 % des femmes. *Pour les facteurs motivants : *Peur de la maladie : 54% *Désir de la prévention :20% *Influence des campagnes : 12% *Antécédents familiaux de cancer : 8% *Pour les barrières : *Peur de la douleur / examen : 44% *Distance géographique : 18% *Manque du temps : 14% *Manque de l'information : 8%

Discussion: *La peur de la maladie est le principal facteur motivant, ce qui souligne l'importance des campagnes éducatives axées sur les bénéfices du dépistage. *Les barrières psychosociales, telles que la peur de la douleur et l'appréhension liée aux résultats, restent des obstacles majeurs. *Les facteurs économiques et géographiques limitent également l'accès au dépistage, particulièrement dans les zones rurales ou défavorisées.

Conclusion: *Cette étude met en évidence l'importance des campagnes de sensibilisation et des recommandations médicales pour motiver les femmes à participer au dépistage du cancer du sein. *Les interventions futures devraient cibler les barrières psychosociales et culturelles, tout en renforçant l'éducation sanitaire et l'accès aux services de dépistage, en particulier pour les femmes à risque élevé.

ID 406- What do increasing pollution levels mean for sore throat – a narrative review

Niva KALLUS

Clalit Healthcare Services, Tel Aviv, Israël

Context: This case discusses a 33 year old male patient who presented over the course of one year (2023-2024) with recurrent episodes of high fever (38-39 ^{o}C), malaise, myalgia, pharyngitis, and adenitis. On physical examination at each time a notable tonsillar enlargement and erythema, as well as exudate were observed. The diagnosis of adult onset PFAPA was made based on ruling out other conditions and clinical course of his disease.

Methods: Case report

Originality: Original

Lessons learned and future implications: FAPA can present in adults — consider it in recurrent pharyngitis with fever Diagnosis is clinical and by exclusion Steroid responsiveness is a strong diagnostic clue Avoid repeated antibiotics; manage as autoinflammatory disease

Discussion: Adult PFAPA underrecognized due to rarity and diagnostic overlap Key differentiator: regular periodicity + rapid steroid response No infectious or autoimmune etiology Awareness critical to prevent unnecessary antibiotics and referrals

Conclusion: While the diagnosis in children is based most often on a set of criteria first proposed by Marshall et al. and later modified by Thomas et al., building on their clinical observations. The latter set of criteria, often referred to as the modified Marshall criteria, they are not applicable to adults as the first criteria requires the patient to be under 5 years old at the first episode. However, this patient presented with all the signs and symptoms of PFAPA (fever ranging 38-39 ^{o}C, sore throat, swollen glands, hoarseness, tonsillar exudate, myalgia, and malaise), excluding age of first onset and thus the diagnosis was determined based on ruling out other conditions and clinical basis. It is unclear whether the hematological disorder he presented is related in this case to the presentation of PFAPA and requires further investigation. This patient illustrates the difficulty of diagnosing this syndrome in an adult due to lack of unifying criteria that exist in pediatrics (modified Marshall criteria) and the need for clinicians to stay vigilant and aware of the adult presentation to prevent unnecessary and potentially harmful use of antibiotics.

ID 478- What is the clinical pathway of women with lipedema ? A mixt study among French patients

Lilach MALATSKEY [(1)] , Evie KEMP [(2)], Dikla AGUR COHEN [(3)]

(1) Azrieli Faculty Of Medicine, Bar Ilan University, Zichron Yaakov, Israël
(2) Nhs Occupational Health Physician (retired), Haifa, Israël
(3) Ruth And Bruce Rappaport Faculty Of Medicine, Technion, Haifa, Israël

Context: Background: Physicians often face substantial personal and professional challenges, leading to high rates of burnout, psychological distress, and an elevated risk of suicide, which can significantly impact both doctors' well-being and patient care. Recognizing these challenges, the Israeli Medical Association established the 'MIFNE' service to provide tailored mental health support for physicians and their families.

Objectives: Aims: This study explores the development, implementation, and impact of MIFNE on physician mental health and identifies key trends in service usage and satisfaction.

Methods: Methods: Data were collected from October 2020 to March 2024. A mixed-

methods approach was employed, using referral data, demographic analysis and feedback from satisfaction surveys to evaluate the service's effectiveness.

Results: Results: In the first three and a half years, MIFNE received 964 referrals, averaging 270 per year, with increases during the COVID-19 pandemic and the October 7th war. Demographic analysis indicated higher service usage among female physicians, residents, and younger doctors. The main reasons for referral were family issues, anxiety, depression, and work-related stress. Satisfaction surveys showed high ratings for accessibility (94%), confidentiality (98%), professionalism (91%), and service quality (84%), with 65% of participants reporting a substantial positive impact on their mental health.

Discussion: The critical need for mental health support programs for physicians has been well-documented, especially in light of rising levels of stress, burnout, and psychological challenges in this profession. Despite growing awareness of the well-being concerns faced by physicians, time constraints, privacy issues, and stigma remain formidable barriers for doctors to access care and support, and initiatives specifically designed to address these obstacles are lacking. The MIFNE service, a pioneering initiative by the IMA, was designed to address these gaps

Conclusion: Conclusions: MIFNE's comprehensive support model effectively addresses the mental health needs of physicians and their families, with the flexibility to develop new services and targeted interventions, particularly during times of crisis. The service's success highlights its potential as a model for global healthcare systems to improve provider well-being and resilience.

ID 2208- What place for advocacy and political engagement? Ethical reflection on the role of the clinician and researcher

Tinsae Abeya GELETA

National Yang Ming Chiao Tung University, Taipei, Taïwan

Context: Hypertension screening and early treatment are essential for preventing severe health complications such as stroke, heart failure, and coronary heart disease. Screening allows for the identification of hypertension at an asymptomatic stage, facilitating timely control before irreversible damage occurs. However, in low- and middle-income countries such as Ethiopia, hypertension screening practices are poorly understood and inadequately addressed in national disease prevention strategies.

Objectives: This study aims to examine the barriers and enablers of hypertension screening practices among middle-aged adults in Ethiopia.

Methods: This study employed a descriptive qualitative research design, conducted between April and May 2025 in Ethiopia. The study used a purposive sampling technique to recruit study participants. Data were collected through in-depth interviews and conducted by an experienced qualitative data collector. The interviews were transcribed verbatim, translated from the local language into English, and inductive thematic analysis was performed using ATLAS.ti software version 7. Finally, the results were presented thematically with thick descriptions.

Results: In-depth interviews were conducted with three participants from rural, urban, and semi-urban areas. An inductive thematic analysis revealed three main themes and seven subthemes related to hypertension screening: Theme one, Personal barriers to hypertension screening; theme two, External barriers to hypertension screening; and theme three, Enablers of hypertension screening.

Discussion: This study examines the barriers and facilitators of hypertension screening practices among middle-aged adults. Findings from thematic analysis and interviews are categorized into three main themes and nine categories. The study identified several barriers to hypertension screening, such as cultural beliefs, limited support from health professionals, community-related factors, inadequate health facility services, and individual-level challenges. Conversely,

enabling factors included community mobilization, the involvement of community and religious leaders, the presence of role models, facility-based screening programs, awareness initiatives, and accessible diagnostic services.

Conclusion: Overall, the findings suggest that barriers to hypertension screening go beyond individual factors. They include community, interpersonal, and health service-related challenges. Addressing these complex barriers necessitates a collaborative effort involving communities, government entities, religious institutions, and non-governmental organizations.

ID 1685- What solutions to improve communication with deaf patients in primary care consultations? The example of video remote interpreting in French Sign Language (FSL)

Chowdhury Md NAVIM KABIR

Government Employee Hospital, Dhaka, Bangladesh

Context: Prevalence of Diabetes Mellitus in South Asian countries is a burning issue. In recent times association of anxiety with newly diagnosed type 2 diabetes mellitus patients have been increasing. In this regard, sub cutaneous Insulin for treating with anxiety can be more effective on both glycemic control and anxiety reduction.

Objectives: Determine the efficacy of early insulin administration on the diabetic patients associated with anxiety disorders.

Methods: 535 patients [age range [(27-45) +_ 2 years] came to Medicine outdoor patient department with complain of insomnia, anxiety from February 2024-August 2025. Printed questionnaire was supplied to the participants for desired data. Participants were advised to do Oral Glucose Tolerance Test (OGTT) under sharp supervision. Patients of different systemic diseases, diagnosed as diabetic, pregnancy were excluded for avoiding bias outcome. Finally,470 patients were included for the study who were advised to start sub cutaneous insulin (3 times per day according to requirement) with practical training and follow-up after 1 month.

Results: Range of Initial Fasting Blood Sugar value of 37 % patient (group A) was (7.2-7.9) mmol/L, 45% was (group B) (8.0-10.5) mmol/L and remaining was (10.6-13.0) mmol/L. The 2 hours after breakfast glucose(2HABFS) for Group A (11.6- 12.5) mmol/L, group B (12.7-14.0) mmol/L, group C (14.3-15.0) mmol/L. In group A, anxiety affected rate was 29%, group B 41% and group C it was 30%. During follow up, the FBS reduction for group A 25%, group B 33%, group C 38%. In 2HABFS, the reduction rate for group A 25%, group B 31 %, group C 39%. In anxiety, group A became 10%, group B 15% and group C 12.5%.

Discussion: Simultaneous use of Sub cutaneous insulin can be a effective prevntive way for controlling diabetes associated anxiety,

Conclusion: Anxiety individually controlled by oral drugs but when it is associated with Diabetes it's management should be started earlier by insulin for its proven reduction capability.

(3) Iweps, Namur, Belgique

Context: Long COVID (LC), a multisystem disorder with persistent symptoms >=4 weeks after a COVID-19 infection, has impacted healthcare systems substantially. In XXX, a care trajectory post-Covid-19 (CT) was launched in July 2022, in which diagnosed LC patients with symptoms >=12 weeks can benefit from reimbursement of treatment costs when consulting healthcare provider(s)(HCP) in primary care for their rehabilitation. In this care pathway, general practitioners have a key position and are point of referral.

Objectives: Identifying the characteristics and healthcare utilization of LC patients included in a CT.

Methods: COVIMPACT is a longitudinal online cohort study in the XXX adult population recruited after SARS-CoV-2 infection, including people suffering from LC. In the last wave, questions focused on CT inclusion, allowing for comparing CT versus non-CT LC respondents. All variables with significant bivariate association with CT inclusion were included in a backward multivariable logistic model.

Results: Among all LC sufferers visiting HCP for their persistent symptoms (N=1246), 5% (N=64) were included in CT while 23% responded to not yet have heard or being informed about this CT. In total, 42% of CT patients were (very) satisfied with their inclusion, 28% answered neutral and 30% were dissatisfied. Being included in CT did not significantly differ among XXX regions, nor was there effect of respondents' age, educational level, ethnicity or urban residency. CT patients were mainly female and had few chronic conditions (p<.01). Compared to non-CT LC sufferers, CT patients had numerous LC symptoms (p<.01), suffered more from breathing and memory problems and persistent fever (p<.05), symptoms lasted longer, majority was not recovered and daily life was strong impacted by LC. Total number of consultations was higher and they consulted specialists (p<.05), physiotherapist (p<.01), mental health professional (p<.001) more frequently than non-CT LC sufferers.

Discussion: About one in three of the included CT patients were not satisfied with the benefits and care delivery received for their Long COVID rehabilitation.

Conclusion: As patients included in CT experience major daily impact of LC compared to non-CT LC sufferers, these CT patients have increased care needs and higher healthcare utilization.

Sameera ALHAJRI, Anees A ALYAFEI,, Sandy SEMAAN, Maryam AL MUSLEMANI, Asma AL NUAIMI

Primary Health Care Corporation,, Doha, Qatar

Context: Healthcare workers (HCWs) are at increased risk of occupational exposure to vaccine-preventable diseases. Immunization protects both staff and patients. Although international guidelines recommend comprehensive vaccination for HCWs, uptake remains suboptimal in many countries, including Qatar. Limited published data exist for the Primary Health Care Corporation (PHCC), the largest primary healthcare provider in Qatar. This study aimed to evaluate vaccination coverage and associated factors among PHCC healthcare workers for hepatitis B (HBV), measles-mumps-rubella (MMR), varicella (VAR), and tetanus-diphtheria-acellular pertussis (Tdap).

Objectives: To measure the vaccination coverage for HBV, MMR, VAR, and Tdap among PHCC healthcare workers between 2020 and 2024, and to explore demographic and occupational factors associated with vaccine uptake.

Methods: A retrospective observational study was conducted using electronic medical records and HR data from 31 PHCC health centers. All healthcare workers employed for at least 3 months during 2020–2024 were included. Vaccination status for HBV, MMR, VAR, and Tdap was retrieved. Descriptive statistics were used to report coverage rates. Chi-square tests and logistic regression were used to identify predictors of vaccine uptake. Statistical significance was set at $p < 0.005$.

Results: Among 7,463 employees, the mean age was 40.8 years, with 65.1% female and 72.2% non-Qatari. Clinical staff made up 64.2% of the workforce. Vaccine coverage was: HBV 16.8%, MMR 5.9%, VAR 1.8%, and Tdap 12.9%. Younger age, female gender, non-Qatari nationality, fewer years of service, and higher education levels were significantly associated with greater uptake. Non-clinical staff had higher HBV coverage, while clinical staff had better varicella coverage.

Discussion: The study reveals suboptimal vaccination coverage in PHCC despite strong policy support. Multiple demographic and occupational disparities were found. These findings highlight gaps in staff immunization and the need for targeted interventions.

Conclusion: Vaccination coverage among PHCC healthcare workers remains below international targets. Strengthening occupational vaccination programs with tailored strategies based on staff characteristics is essential to enhance coverage and improve healthcare safety.

Corresponding author: Sameera Alhajri, shajri@phcc.gov.qa

ID 1274- When Continuity Makes the Difference: A Family Doctor's Role in the Diagnosis of a Ovarian Mass in an Adolescent

Sameera ALHAJRI, Anees A ALYAFEI, Sandy SEMAAN, Maryam AL MUSLEMANI, Asma AL NUAIMI

Primary Health Care Corporation, Doha, Qatar

Context: Healthcare workers (HCWs) are a priority population for vaccination due to their high exposure risk and key role in maintaining healthcare system resilience. While COVID-19 vaccination campaigns have achieved notable success globally [1], seasonal influenza uptake remains inconsistent. This study assessed COVID-19 and seasonal influenza vaccination coverage among HCWs at the Primary Health Care Corporation (PHCC) in Qatar between 2020 and 2024, and identified associated demographic and occupational determinants.

Objectives: To measure COVID-19 and seasonal influenza vaccine coverage among PHCC HCWs and analyze associations with age, gender, nationality, job role, service duration, and education.

Methods: A retrospective study was conducted using data from PHCC's electronic medical records and Human Resources Database, covering 31 health centers. All HCWs employed ≥3 months were included. Descriptive statistics summarized uptake. Chi-square tests assessed associations with demographic and occupational factors. Significance was set at $p < 0.05$.

Results: Among 7,463 HCWs, COVID-19 vaccine uptake was 94.05% (18,844 doses). Influenza

coverage was 65.20% (4,866 HCWs, 16,533 doses), exceeding the global average of 41.7% [4] but below the WHO 75% target [2]. Higher uptake was associated with older age, non-Qatari nationality, female gender (for COVID-19), and shorter service duration ($p < 0.05$). Education level was significantly associated with both vaccines. Clinical role was significant only for COVID-19.

Discussion: COVID-19 uptake aligns with high-income country benchmarks [1], while influenza coverage remains suboptimal. Post-COVID vaccine fatigue, shifting risk perception, and reduced seasonal vaccine focus may explain this decline. Tailored strategies—such as reminders, peer modeling, and education—can improve uptake. Older HCWs showed higher compliance, consistent with global studies. Females had higher COVID-19 uptake; males had higher influenza uptake, reflecting gender-based variation. Non-Qatari staff had higher uptake, likely due to institutional requirements. While job role did not affect influenza uptake, non-clinical staff had higher COVID-19 coverage.

Conclusion: Sustained institutional efforts are needed to reduce vaccine fatigue and improve annual influenza uptake, especially among younger, Qatari, and longer-serving HCWs. Tailored education and mandates may strengthen future compliance and protect healthcare system integrity.

ID 797- When Familiar Support, Exercise and Modern Therapy Converges: A Diabetic Turnaround

Praveena MAHALINGAM

Nhs, London, Royaume-Uni

Context: Cervical cancer is highly preventable, yet women living with HIV (WLWH) remain six times more likely to develop it than the general population (WHO, 2020). In the UK, NICE guidelines recommend annual cervical screening for WLWH aged 25–64, but adherence is inconsistent. Primary care, as the first point of patient contact, is ideally placed to uphold the principles of liberty, equity, fraternity, and humanism by ensuring inclusive, accessible, and patient-centred preventive care. This audit explores how a London general practice addressed disparities in cervical screening uptake among WLWH through system-level and educational interventions

Objectives: To assess adherence to annual cervical screening recommendations in WLWH, identify barriers to engagement, and evaluate interventions designed to promote equitable and humanistic care.

Methods: A retrospective audit was conducted using the EMIS database to identify all WLWH aged 25–64 registered between 2020–2023 (n=38). Data were reviewed for coding accuracy, recall intervals, and reminder notifications. Interventions included tailored patient communication, staff training on HIV-specific screening guidance, and patient education regarding cancer risk and screening importance. Outcomes were measured through improvements in coding accuracy and screening uptake.

Results: 84% of patients were coded correctly; however, only 40% underwent annual screening. Barriers included inconsistent recall intervals, variable reminder systems, and limited patient understanding. Following intervention, screening uptake improved by 30%, supported by improved staff confidence and clearer patient communication. These findings demonstrate that structured, human-centred approaches can significantly reduce inequities in preventive care.

Discussion: A systematic review found that WLWH face barriers such as fear of results, limited access, and system inefficiencies (Khalil et al., BMC Cancer, 2021). Women receiving tertiary HIV care without primary care input are less likely to be screened (Cohen et al., Indian J Cancer, 2021), highlighting the need for integrated models. Practices should update recall systems, train staff on annual screening criteria, send automated reminders, and offer consultations for non-engagement to enhance participation and trust.

Conclusion: Embedding equity and humanism into primary care can transform cervical screening access for WLWH. By addressing systemic and interpersonal barriers through integrated care and tailored communication, primary care can lead the way in reducing cervical cancer disparities across Europe.

ID 1306- When Intoxication Leads to Seizures: What Does the Emergency Department Reveal?

Vytenė MENKEVIČIENĖ

Polyclinic Of Alytus, Alytus, Lituanie

Context: Despite the proven health benefits, the rate of breastfeeding remains low according to WHO data. Breastfeeding counseling has been shown to increase the frequency of exclusive breastfeeding (Sikorski et al. 2003), so providing support to all women, is one of the most important steps in changing these statistics. Unfortunately, according to scientific data (Levinienė et al. 2013, Marks et al. 2015, Biggs et al. 2020), medical professionals are not well trained to support breastfeeding women.

Methods: As a family doctor, I often found myself not being able to provide breastfeeding woman with the information they needed. This encouraged me to seek opportunities for building my knowledge and becoming a small but important change, I became a certified lactation consultant (CLC). In this way, I started to provide real support to women after childbirth, rather than just being a passive source of information.

Originality: I am one of the very few general practitioners in my country that is also a certified breastfeeding specialist. I realise that I will not be able to create a significant change in breastfeeding statistics on my own, but I still believe that you need to start the change where you are.

Lessons learned and future implications: In order to provide appropriate support to all women after giving birth, it is important to develop easy-to-use and accessible sources of eviden-based information on breastfeeding for healthcare professionals, such as mobile applications. To increase the availability of breastfeeding support to all women, regardless of their financial situation, a breastfeeding specialist should be part of the primary healthcare team.

Discussion: My goal is to encourage my colleagues to expand their knowledge about breastfeeding by inspiring them with my example, so they can provide timely help and much-needed support to women after giving birth. I became a trainer, giving presentations to colleagues on breastfeeding topics and participating in projects aimed at promoting breastfeeding in my country.

Conclusion: Knowing that providing information about breastfeeding and supporting women can increase the duration of breastfeeding, which will also have a positive impact on women's emotional health, each of us can become an important and so needed change.

ID 779- When is not only a matter of health

Vineet NAIR

Schulich School Of Medicine & Dentistry At Western University, London, Canada

Context: Many family doctors feel trapped by their own schedules—constantly behind, unable to meet patient demand, and with little time left for themselves. I felt similarly and thought that was how practice was just supposed to be. Patients waited weeks for appointments, staff were stressed, and a "good doctor" was supposed to be busy and running behind. Learning and implementing Advanced Access—a scheduling model designed to balance supply and demand so clinicians can “do today’s work today”—transformed my practice, my patients’ experience, and my own sense of control.

Methods: Implementation began with the understanding of the principles and learning the steps required: 1. Assess Current State (using the fundamental formula that underlies all of our practices) 2. Team Meetings and Buy-In 3. Eliminate Backlog 4. Increase Supply 5. Decrease and Control Demand

Originality: This change was not imposed by administration or policy—it came from my desire to improve my practice life. The focus was on practical, low-cost steps any clinician can apply. It also linked scheduling reform to personal well-being, proving that system improvement can directly enhance professional satisfaction.

Lessons learned and future implications: My experience with Advanced Access has been clear: I am able to have more control over my practice and could finish on time and enjoy real flexibility. My patients could usually be seen the same or next day; staff felt calmer and more capable; and my stress levels dropped. With an organized and responsive schedule, this can be the reality for more of us.

Discussion: The success of Advanced Access lies in its simplicity. It does not require new software or funding—only the commitment to measure, adjust, and stay consistent. It is fundamental in its nature and helps with the most important aspect of your patients' care - their ability to see you when they need to!

Conclusion: Implementing Advanced Access was the best practice change I ever made. It improved access for patients, strengthened team morale, and gave me back control of my time and my freedom.

ID 1204- When the eyelid falls… but the alarms rise

Nathan LAGARIGUE

University Hospital Of Bordeaux, Bordeaux, France

Context: Secondary use of health data has gained increasing attention, especially since the COVID-19 pandemic. While hospitals have long relied on Health Data Warehouses (HDWs), primary care is now developing its own systems for data collection and valorization, opening new perspectives for data exploitation. However, the parallel development of hospital and primary care HDWs risks fragmentation, making their interconnection a key lever to improve care coordination, analyze patient pathways, and strengthen territorial health policy.

Objectives: This study aimed to identify the main issues, barriers, and facilitators to linking hospital-based HDWs with those from primary care, in order to understand the conditions for effective and meaningful data integration.

Methods: Nine semi-structured interviews were conducted with general practitioners and professionals from public organizations involved in the regulation, organization, and governance of health data and services. An inductive thematic analysis was used to identify tensions, expectations, and potential courses of action.

Results: Results indicate a strong interest in the secondary use of primary care data, seen as a lever for research, care quality, and alignment of policies with local needs. However, support is conditional on an ethical, secure, and transparent framework. While convergence of HDWs is widely desired, significant barriers remain, including fragmented governance, lack of interoperability, cultural tensions, asymmetries in data access, and mistrust toward certain institutions. Identified facilitators include recognition of data producers, concrete feedback on data use, and shared governance. Overall, successful interconnection relies on fostering trust and demonstrating tangible utility for stakeholders.

Discussion: This study highlights that primary care professionals are supportive of data reuse and HDW interconnection when clinical utility is clear, feedback to contributors is meaningful, governance is transparent and inclusive, and institutional trust is established. These conditions extend beyond technical feasibility, reflecting deeper human, professional, and organizational expectations.

Conclusion: In conclusion, linking hospital and primary care HDWs depends primarily on shared governance, trust among actors, and collective construction of meaning around data. Understanding these socio-organizational requirements is essential to harness the full potential of health data for research, quality improvement, and territorial health system planning.

Andrea BALBARINI [(1)], Amanda Joan KEEFE [(2)]

(1) Ausl Modena, Lama Mocogno, Italie
(2) Asfo, Aviano, Italie

Context: Point-of-care ultrasound (POCUS) has become an increasingly valuable tool in general practice (GP), allowing clinicians to enhance diagnostic accuracy and guide frontline decisions. Among its most relevant applications for GPs, are the assessment of pulmonary diseases (such as pneumonia, pleural effusion, and interstitial syndromes) and the evaluation of suspected lower limb deep vein thrombosis (DVT) through compression ultrasound (CUS). Integrating POCUS into daily practice can optimize patient management and reduce the need for immediate referral to secondary care.

Objectives: The objectives of the workshop include: acquiring basic knowledge of lung ultrasound in common respiratory conditions, understanding of CUS in suspected lower limb DVT and learning practical skills to perform focused POCUS examinations.

Teaching method and workshop: A blended format combining short lectures with a hands-on session will be used. Faculty will provide interactive teaching, demonstrations, and guided practice on ultrasound machines. After a brief introduction on ultrasound in General Practice, the first

Expected outcomes: Participants will acquire essential knowledge of POCUS applications in pulmonary and vascular medicine, practice key ultrasound techniques, and improve confidence in integrating sonographic findings into clinical reasoning in primary care.

Conclusion: This workshop provides an accessible and clinically relevant introduction to the use of POCUS in pulmonary and vascular medicine for GPs. By combining theoretical knowledge with practical skills, it aims to empower primary care physicians to adopt ultrasound as a valuable extension of their clinical examination.

ID 1424- When the Story Behind the Symptoms Emerges

Pedro Alejandro GONZALES FLORES, Oswaldo Franco YBARCENA ÁLVAREZ, Sebastián MELGAR TORENA, Josep GUIL SANCHEZ, Samuel Enrique BETANCURT POLO, Javier Rodrigo ROMERO ARGOTE, Adriana GARCÍA-PANTALEÓN PORCUNA

Mollet's Hospital, Mollet Del Vallès, Espagne

Context: Within the climate emergency, the use of MDI (metered dose inhalers) contributes to the increase in atmospheric CO2. These medications are widely used in patients with respiratory conditions, but the type of inhaler should be changed to dry powder or fine mist to improve environmental sustainability.

Objectives: 1. Establish a clinical and therapeutic profile of respiratory patients treated in the emergency department. 2. Determine the number of MDI inhalers both upon admission and upon discharge from the hospital.

Methods: Medical records of patients treated in the emergency department between January 1 and April 30 ,2025 who presented with exacerbation of bronchial asthma or chronic obstructive pulmonary disease (COPD) were reviewed. Demographic variables (age, sex), clinical variables (comorbidities), and treatments used were obtained. The data were processed using the SPPS program.

Results: A total of 218 patients were enrolled, of whom 89 had asthma and 129 had COPD. In the asthma group, 57.3% were women, while in the COPD group, 81.4% were men. The average age in the asthma group was 51.2 ± 10.2, while in the COPD group it was 74.6 ± 18.4 years. Main comorbidities in both groups were high blood pressure, diabetes mellitus and dyslipidemia. Total number of MDI inhalers in the asthma group prior to admission was 78 (ratio 0.87), while in the COPD group it was 140 (ratio 1.08). At discharge, the number was 90 (ratio 1.01) in the asthma group and 176 (ratio 1.36) in the COPD group. Rescue MDI use was +85.7% for salbutamol and +76.9% for ipratropium in the asthma group, and +37.14% for salbutamol and +23.53% for ipratropium in the COPD group.

Discussion: Use of MDI devices whose propellant gases contribute to the increase in environmental CO2 is widespread in the management of respiratory patients worldwide, and their widespread use has grown exponentially in recent decades. Use is even greater when it comes to rescue medication.

Conclusion: 1. There is a high proportion of MDIs in the patients studied. 2. The use of MDIs is even greater upon hospital discharge and when used as rescue medication. 3. The use of DPI and SMI devices should be promoted.

ID 1506- When the superficial veins speak: a case report of recurrent superficial thrombophlebitis

Pascaline FAURE

Sorbonne University, Paris, France

Context: Given the whopping number of drugs on the market, finding a unique brand name has become a major challenge for manufacturers. Therefore, naming agencies must imagine novel strategies that do not contravene health authorities' stringent regulations.

Objectives: The main objectives of our study were to (1) review the most widely used

naming strategies and (2) identify the novel ones, based on a corpus of all 220 drugs that were approved by the FDA between 2021 and 2025.

Methods: We conducted a mixed analysis. The primary outcome was the lexicological matrices. We first examined how the names were formed from a linguistic point of view. We investigated whether some letters and sounds were more popular than others. We checked whether the names or part of the names had a meaning in English, and whether they conveyed an imagery or a value. Eventually, we extracted and analysed those that were particularly interesting from a linguistic and a semantic point of view.

Results: 80% of the names contained three or more syllables. 40% contained the letter Y. 9% exhibited double letters. 4% included a silent H. 12% started with O. 4% had an unconventional structure. 15,5% contained the [vi] sound. From a semantic point of view, 80% of the names were motivated either because they embedded part of the name of the drug's molecule or included a reference to the drug's medical indication. 14% embedded part of a real word that had a meaning in English.

Discussion: Most names have three syllables to be distinctive. Distinctiveness is also enhanced using downstroke letters like Y, and including a silent H. Several names embed meaningful words that convey positive values. Developing brand names that include double letters and use imageries to address specific consumers (e.g., African-Americans) are among the most novel naming strategies.

Conclusion: The FDA recommends that the brand name be neutral not to influence consumers and prescribers. But the prescription drug market is highly competitive. Therefore, developing a unique name is paramount for pharmaceutical companies. As for the future, naming agencies will need to discover unusual sequences of letters, borrow images from new fields and rely on AI.

Context: Artificial Intelligence (AI) is increasingly recognized as a transformative force in healthcare, offering opportunities to enhance diagnostic accuracy, streamline administrative processes, and improve patient outcomes. In resource-constrained settings like Kosovo, the integration of AI into primary care could address systemic challenges such as workforce shortages, fragmented health data systems, and the growing burden of chronic diseases.

Objectives: This study aims to investigate the integration of Artificial Intelligence (AI) in diagnostic medicine within Kosovo's primary healthcare system, focusing on the perspectives of family physicians. The primary objectives are:To explore how family physicians in Kosovo perceive the potential benefits and challenges of incorporating AI technologies into primary care.

Methods: Using a qualitative research design, semi-structured interviews were conducted with approximately 70 family physicians across diverse regions of Kosovo. Participants were selected through purposive sampling to ensure variation in experience, specialty, and geographic context. Thematic analysis, supported by NVivo software, was employed to identify key patterns and insights.

Results: Preliminary findings from the interviews indicate that family physicians in Kosovo recognize the potential benefits of AI in enhancing primary care delivery. Many participants expressed optimism about AI's ability to improve diagnostic accuracy and reduce the burden of administrative tasks. For instance, several physicians noted that AI tools could assist in identifying patients at risk for chronic diseases, enabling early interventions and personalized care plans.

Discussion: The integration of AI into primary care in Kosovo presents both opportunities and challenges. The positive perspectives of family physicians suggest a willingness to embrace technological advancements that can enhance patient care. However, addressing ethical concerns and ensuring that healthcare providers are adequately trained to use AI tools are essential steps in the implementation process. Moreover, fostering collaboration among stakeholders, including policymakers, healthcare administrators, and technology developers, is crucial for creating an environment conducive to AI integration By working together, these stakeholders can develop guidelines and best practices that prioritize patient care while leveraging the advantages of AI technologies.

Conclusion: The integration of AI in primary care has the potential to transform healthcare delivery in Kosovo, as highlighted by the perspectives of family physicians in this study. This study contributes to a growing body of literature on AI in primary care by centering the voices of frontline practitioners in a low-resource European context.

Maja ZELJKO [(1)] , Emanuela MUSTAI [(2)]

(1) Johannesbad Klinikum, Furth Im Wald, Allemagne
(2) Sanaklinik, Cham, Allemagne

Context: 38 Year old Pat.has consumed alcohol since the age of 12.She has not had a period of abstinence since the age of 12 no even during pregnancy,during pregnancy consum only reduced.

Methods: After clinical deterioration Family took the Pat. first to family doctor and after check to an acute hospital where liver cirrhosis CHILD C 13 points was diagnosed with Ascites,splenomegaly,encephalopathy GRAD III, esophageal varices GRAD II and the pat.is on the waithing list for transplantation registered with requirement to remain abstinent for 1 Year and to make long -term detoxycation Therapy.After 4 Weeks in acut Hospital the pat.was transferred to a long-term Detx Clinic.In admission laboratory and ultrasound liver cirrhosis CHILD C 10 points was diagnosted with encephalopaty GRAD I-II,normochromic normocytic Anemia ,thrombocytopenia,esophagus varices GRAD I-II and hypokalemia.In Ultrasound liver cirrhosis with splenomegaly and minimal ascites.After 5 Month of abstinence by Clinic discharge the pat.had liver cirrhosis CHILD B 8-9 points,normochromic Anemia with Thrombocitopenya.After 1 Year abstinence th pat.came again to alcohol rehab Clinic for a Long-Term Therapy and on admission labaratory and ultrasound was diagnosed liver cirrhosis CHILD A 5 points with out Anemia and Thromocytopenia.

Originality: Liver cirrhosis CHILD C is a classification for decompensated liver cirrhosis ,carrying a poor prognosis with a 1-year survival rate of approximately 45-49%,and a 2-year survival rate around 35%..In this case we have seen that by alcoholic liver cirrhosis with abstinence pat.can remove in CHILD A with much better survival rate.

Lessons learned and future implications: From this case we have learned that abstinece by alcoholic liver cirrhosis can improve life expectancy.It is very impotrant to have alcoholic advice center and family doctor who can advice the patient and Family.

Discussion: Liver cirrhosis CHILD C has very shortly life expectancy and it is very important ro recognize who has problem with alcohol and to motivate to alcohol treatment.

Conclusion: From this case we have to learn how important is prevention od alcohol illness,to have advice center for young people to explane what does it mean alcohol dependence.Very important is to have a family to suport people who have problem with alcohol,and to have good contact with Family doctor.

Marc BRODSKY, Jason STARR, Krishnan NARASIMHAN

Stamford Health, Stamford, États-Unis

Context: American Medical Association (AMA) endorses financial health as a part of well-being programs for medical residents. Medical education may contribute to debt, impose time constraints to develop financial competencies, and delay savings. The medical literature describes financial planning aspects of medical education that were intended to foster personal financial well-being such as meeting current and ongoing financial obligations, feeling secure about future fincances, and making choices that allow enjoyment in life.

Objectives: To evaluate change in knowledge, skills, and attitudes of medical residents who participate in a learning activity in financial planning that may be related to workforce well-being which may impact burnout prevention and employment retention.

Methods: Medical residents at Stamford Health are participating in a financial planning learning activity during the 2025 - 2026 academic year as part of the standard didactic curriculum. We estimate a convenience sample size of current residents (N=72) in the medicine, family medicine, obstetrics and gynecology, and surgery residency programs. At the beginning of the first financial planning session, the medical residents were asked to self-administer a SurveyMonkey. Then, at the end of the third session (the last session), the medical residents will be asked to complete a post-survey to evaluate change in financial planning knowledge, skills, and attitudes. Paired t-tests using a p-value of 0.05 will be performed for each item between pre- and post- responses. Descriptive statistics will include PGY level and residency program. Financial planning knowledge, skills, and attitudes will be measured using Likert scale of 1 (strongly disagree) to 5 (strongly agree).

Results: Ten family medicine residents have completed the pre- survey. Poster will update pre- and post-survey results.

Discussion: Medical education literature describes previous financial wellness curricular development and implementation. Financial well-being may relate to the scope of physician wellness that addresses distress, burnout, and depression. The discussion section will compare findings of this study with previous studies, acknowledge limitations, and suggest future research directions.

Conclusion: Preliminary findings of this convenience sample of medical residents who are participating in a financial planning curriculum represent low quality of evidence and follow-up suggestions will be made to address limitations of interpretation of this data.

Context: Stimulation of the vagus nerve influences biomarkers associated with both the hypothalamic–pituitary–adrenal (HPA) axis and the autonomic nervous system.

Objectives: The goal of the study was to evaluate the effect of transcutaneous vagus nerve stimulation (tVNS) on stress biomarkers and related symptoms and compare the effect of unilateral and bilateral stimulation.

Methods: Total of 37 participants remained throughout the entire study. One-centimeter hair segments were taken and analyzed, representing cortisol and cortisone accumulation over the most recent month. The segments were taken before the study and after 4 weeks of stimulation. Three questionnaires (GAD-7, PHQ-9, PSQI) were used to evaluate anxiety and depressive symptoms as well as sleep quality during the study.

Results: Analysis of hair cortisol showed statistically significant reduction across the full sample ($n = 37$, $V = 514$, $p = 0.013$), with no significant change following unilateral stimulation ($n = 17$, $p = 0.159$) and a significant decrease in cortisol in the bilateral group ($n = 20$, $V = 165$, $p = 0.024$). Cortisone reduction was observed in the full sample ($p = 0.059$), with no significant change in the unilateral group ($p = 0.431$) and a near-significant effect in the bilateral group ($p = 0.058$). Changes in cortisone were moderately and positively correlated with changes in cortisol (Spearman's $\rho = 0.50$, $p = 0.002$). Significant improvements were observed across all self-reported measures following four weeks of VNS. PHQ-9 decreased significantly - total sample $n = 37$, $p < 0.05$, unilateral $p = 0.0005$ and bilateral $p = 0.002$. GAD-7 also showed significant reductions overall ($p < 0.05$), and in both subgroups ($p = 0.002$ unilateral; $p = 0.008$ bilateral). PSQI improved significantly in the full sample ($p < 0.05$) and in both groups (unilateral $p < 0.05$ and bilateral $p < 0.05$).

Discussion: TVNS may reduce long-term cortisol accumulation while improving depression, anxiety, and sleep outcomes. The findings highlight bilateral stimulation as particularly effective for modulating chronic stress physiology, although further research is needed to confirm these effects.

Conclusion: These findings support the potential of tVNS as a non-invasive intervention targeting both physiological and psychological aspects of stress-related disorders.

ID 2128- Working With Women in Situations of Vulnerability Based on the Trajectory of Malala Yousafzai

Ayeisha ASIM

Nimdta, Londonderry, Royaume-Uni

Context: General Practice (GP) workforce shortages are well established, with one strategy being to inspire more medical students into a career in primary care. The factors that influence a medical student's career choice are well described, including the active role of General Practitioners in undergraduate medical education. However, less is known about the perceptions of General Practitioners about their role in undergraduate medical education and what factors enable or inhibit this.

Objectives: To identify the facilitators and barriers faced by General Practitioners when engaging with undergraduate medical education, as reported in the literature and through a consultation exercise.

Methods: A scoping review methodology was conducted according to the six-stage framework developed by Arksey and O'Malley (2005) and enhanced by levac et all. OVID Medline, Embase and Web of Science, were searched for the relevant concepts, and records were screened at abstract and full-text levels. Data extracted was analysed and emerging themes were identified by thematic analysis as advised by Braun and Clarke (2006). The findings of the scoping review were then presented,as the 6th step of scoping review, to the stakeholders in interviews, which included Teaching GP, non-teaching GPs, members of RCGP, members of DOH and NIGPCPA.

Results: 1088 unique articles were initially identified and screened at the abstract level, then at full text level. 10 articles were identified for inclusion. Predominant themes identified included lack of empowerment, respect, funding, and recognition. Further, pre-existing workload and the valuing of General Practice

and tutors played a determining role in GP Tutor's involvement with undergraduate teaching.

Discussion: The identification of facilitating factors and barriers through this reserach allows policy makers to form informed policies that increase GP tutors engagement with Medical students, increasing the quantity and quality exposure of medical students to Primary care, thereby affecting their fuiture career choices in favour of General Prcatice.

Conclusion: The scoping review highlighted the increased workload, financial undercompensation for GPs and lack of respect as the key inhibiting factors, while contrastingly, a sense of empowerment and value from the students and universities, as a motivational factor the GPs, to teach medical students in Primary care.

ID 886- Workplace exercise programs for improve health and work productivity

Olgun GÖKTAŞ

Uludağ University Family Health Center, Bursa, Türkiye

Context: There are some differences between countries in the practice of family medicine, which is the basis of countries' health systems and has a complex structure. These different characteristics make it difficult to develop family medicine standards globally. Family medicine practice is a medical discipline and has core values. Today, different practices of family medicine among countries lead to deviations from the core principles.

Objectives: It is important to clarify the standards in terms of the application of the basic principles of family medicine for acting for more liberty, equity, and fraternity. The Göktaş definition of family medicine/general practice raises awareness in the literature for this purpose.

Methods: The Göktaş Definition in 2018 in the literature added the rights, freedoms, spiritual power, and personal agenda of the family physician to the definition made by WONCA Europe (World Organization of Family Doctors) in 2011. Prepared in this direction, the Global Health Project puts WONCA, the World Health Organization (WHO), and the United Nations (UN) in an important position regarding family medicine.

Results: These institutions are invited to cooperate in this project. For this purpose, information on family medicine standards applied by the Family Physicians' Associations of the countries is collected and shared with www.fmgpglobal.world. Finally, the global revision and integration of these standards is aimed.

Discussion: With the global horizon project of the Göktaş Definition, a global healthcare model acting for more liberty, equity, and fraternity will be developed on the basis of family medicine. The cooperation of WONCA, WHO and the UN is important.

Expected outcomes: The Göktaş Definition of family medicine/general practice is the pioneer of the Global Health Project for acting for more liberty, equity, and fraternity.

Gurinder DOAD

Context: Amlodipine is one of the dihydropyridine commonly used to treat hypertension. We present case of a young woman who noticed gum hypertrophy 2 months after starting the amlodipine

Methods: Observation made. Pt was seen by Dentist and agreed the amlodipine most likely culprit Prior to medication use , she had regular check up with dentist and her gums were normal She took no other medications except amlodipine which was started after she was diagnosed with hypertension She had no history of gum bleeding. She had regular diet consisting of fruits , vegetables and proteins including fish

Originality: Gum hypertrophy from dihydropyridine amlodipine is rare but it's possible this may be due to under reporting

Lessons learned and future implications: Advise patients before starting and increasing to maximum dose that gum hypertrophy is a rare possibility which may not resolve after discontinuing the medication

Discussion: Precise mechanism for this adverse effect of gum hypertrophy due to amlodipine remains elusive. However, there exist complex interplay between amlodipine, oxidative stress,inflammatory responses and tissue remodeling process within gingival tissues our patients gum hypertrophy did not resolve after discontinuation of amlodipine

Conclusion: Amlodipine common calcium channel blocker used to treat hypertension can cause gum hypertrophy which patients need to be made aware of before starting the medication and needs to have their gum examined regularly

ID 484- Wrist-type home blood pressure monitoring device improves usability and preserves sleep quality compared with conventional ambulatory monitoring

Amina SMAILOVA

Context: According to Health XXX surveillance data, the incidence of first-episode acute rheumatic fever (ARF) hospitalisations among Māori has declined by approximately 35% when comparing 2007/2008 with 2024/2025.

Objectives: Guided by Te Tiriti o Waitangi and an explicit equity-focused approach, a comprehensive framework of prevention and care initiatives has been implemented. This includes regular updates to national clinical guidelines for sore throat management, ARF, and rheumatic heart disease, alongside ongoing review and prioritisation of actions within the Rheumatic Fever Roadmap 2023–2028.

Methods: Community-embedded services work in prevention and further care Hauora providers, school clinics, Mana Kidz programme, providing nurse-led care for >34,000 children across 88 South Auckland schools, and a targeted “swab and treat” local pharmacy programme in high incidence rate areas (June 2024–June 2026), delivering timely sore throat assessment, swabbing, and antibiotic treatment. In parallel, support of community-centred clinical studies strengthens prevention and management strategies. For example, a recent study published, which is under review, in PLOS Global Public Health demonstrates that subcutaneous benzathine penicillin (SCIP), administered 10-weekly, is safe, well tolerated, and improves adherence.

Results: Despite this reduction, the risk profile has remained unchanged, with the highest incidence consistently observed among children aged 5–14 years. In 2024/2025, a total of 194 first-episode ARF hospitalisations were reported nationwide; Māori were approximately 18 times, and Pacific peoples 70 times, more likely to be hospitalized than the non-Māori, non-Pacific population.

Discussion: These inequities are further amplified in rural and remote communities, positioning rural general practitioners as a critical component of the coordinated, multi-organisational response to ARF in XXX.

Conclusion: Despite these advances, rural GPs remain pivotal, as they encounter the main gaps in care delivery. Their experiences and insights must actively inform the implementation of national programmes and integration of local initiatives, ensuring that ARF prevention strategies are both effective and contextually relevant across rural XXX.

Context: Bariatric surgery has become a powerful therapy for patients with obesity and type 2 diabetes mellitus (T2DM) whereby significant weight decreases are achieved, and metabolic remission can take place. However, remission rates differ widely, making predictive tools that support personalized care crucial.

Methods: The intent of the present study was to generate and test machine learning (ML) and deep learning (DL) models for predicting T2DM remission following bariatric surgery in addition to detect major clinical and behavioral predictors through explainable AI approaches.

Originality: Cross-sectional study at King Fahad Specialist Hospital from January to April 2024. Clinical, anthropometric, and behavioral data were used to train classification models (10 ML and 4 DL).

Lessons learned and future implications: SHapley Additive exPlanations (SHAP) were employed to interpret the models. Analysis of performance metrics including ROC AUC, accuracy, precision, recall, and F1-score was also performed.

Discussion: Bottleneck Network showed the highest ROC AUC of 0.889, followed by Random Forest (0.863). SHAP analysis revealed the percentage of weight regain, BMI, A1c levels, and dietary habits as significant predictors.

Conclusion: Explainable AI models provide a logical and interpretable model to predict T2DM remission after bariatric surgery for the personalized decision-making and personalized care of patients. Keywords Bariatric surgery, Hypoglycemia, machine learning
